The countries within the boundaries of the Argentine Republic which are not included in the territories of any one of these thirteen republics, occupy perhaps one-fourth of its area. They are, on the north, the Gran Chaco, or Great Desert, and on the south, the whole tract south of the old boundary-line, with the exception of that portion which, by a decree of the junta of Buenos Ayres, has lately been appropriated to that state. As the inhabitants of both countries are, with few exceptions, nomadic tribes, there are no towns. But the Spaniards have formed a settlement on the Cusu Leubu, called Nuestra Señora del Carmen. It is built on the northern banks of the river, about fifteen miles from its mouth. The houses are small and irregularly placed. The population consists of about 2000 persons, of whom 500 are negroes. It has some commerce with the tribes of the Puelches, who live on the plains west of the town. Carmen sends a representative to the junta of Buenos Ayres. To keep the Indians who live on this large plain in due restraint, and to prevent them from invading the white settlements, the government of Buenos Ayres has established two lines of fortifications. A few forts have been erected along the course of the Cusu Leubu at those places where there is an easy passage over the river. The other line of forts runs along the western boundary-line of the state of Buenos Ayres, from the Bahia to the Fort of Melinque, and this line is intended to protect more immediately the settlements which lie to the east of it. But no line of forts protects the inhabitants of San Luis against the invasion of the native tribes.

Manufactures.—The most important branch of manufacturing industry is that of *ponchos*, or oblong square pieces of woollen cloth, with a hole in the middle, to pass the head through; they are used by the gauchos and other people as cloaks. The finest are made of vicuña skins, in the town of Santiago del Estero. Some woollen fabrics for men's and women's dresses are also made, as well as saddle-cloths. In some parts some coarse cotton-cloth was formerly made by the country-people for their own use, but this branch of domestic industry has been nearly abandoned since the introduction of British manufactures.

Commerce.—The internal commerce of the states is considerable, as most of them have some products which are either not at all or only to a small amount raised in the neighbouring states. Thus the cotton of Corrientes and of Catamarca, and the wines and brandies of Rioja, San Juan, and Mendoza, are transported from the places where they are grown, to the states which are most distant from them. Under the Spanish dominion great numbers of horses and mules (60,000) were annually sent to Peru and Bolivia, but at present the number exported to those countries appears to be small. The commerce by land with Chile is not considerable, being almost limited to the exports of the state of Mendoza, which have been already mentioned.

The maritime commerce of these countries, while they were under the sway of Spain, was not great. The official valuation of the average imports from 1792 to 1796, inclusive, did not exceed 2,606,754 Spanish dollars (586,520*l.*), though every article was sold at an exorbitant price. Since these countries have obtained their independence, and have been accessible to the vessels of all nations, the imports have increased so much that, at the comparatively low prices at which articles are now sold in those countries, their value in peaceable years amounts to about 7,000,000 dollars (1,575,000*l.*). But this commerce has experienced great interruptions and vicissitudes. Between 1821 and 1825 it was in the most flourishing state. From 1826 to 1828 foreign vessels were excluded by the Brazilian blockade. After that time the country was distracted by civil wars and political revolutions. Another interruption has recently been caused by the blockade of the French, which still lasts. Before the Brazilian blockade, the port of Buenos Ayres was the only place whence the produce of these states was sent to foreign countries; but since that time great part of the northern provinces have sent their produce to Monte Video, and received foreign merchandise by the same way. In 1822 the imports of Buenos Ayres amounted to 11,267,622 dollars (2,539,715*l.*), viz.:—

---

[*] A load or cargo is equal to about 200 lbs.

	Spanish Dollars.
Great Britain sent to the value of .	5,730,952
France	820,109
Holland, Germany, Sweden, and Denmark	552,187
The Mediterranean . . .	848,363
The United States of North America	1,368,277
Brazil	1,418,768
China	165,267
The Havanna	248,025
Chile and Peru	115,674
	11,267,622

In the following years the value of the imports increased considerably; but after the Brazilian blockade, when Monte Video began to share this trade with Buenos Ayres, it decreased to the above-stated amount of about seven millions, which diminution however may partly be attributed to the political disorganization which has prevailed up to the present time.

The goods imported from Great Britain into Buenos Ayres consist of cotton cloth, plain and printed calicoes, linens, woollens, and silks; and besides hardware and cutlery, coarse and fine earthenware, glass, iron and steel, leather, tin and pewter wares, and tin plates, arms and ammunition, and a number of minor articles. France imports superfine cloth and linens, merinos, cashmeres, silks and cambrics, lace, gloves, shoes, silk stockings, looking-glasses, fans, combs, and jewellery. From Germany are imported cloth, linens, and cottons; from Holland, cloth, linens, gin, butter and cheese, and Westphalia hams; from Belgium, arms, especially swords and pistols; and from Sweden, iron, cordage, canvas, pitch, tar, and deals are imported. From the Mediterranean, Sicilian and Spanish produce are sent, of which the most important are the cheap red wines of Sicily, the common wines of Catalonia, brandies, olive oil, maccaroni, and dried fruits. They were formerly brought by British vessels from Gibraltar, but are now mostly carried in Sardinian ships. From Spain are imported some serges and silks, velvets, and Spanish snuff. Formerly great quantities of paper were brought from Spain, but that article is now sent from Genoa. From the United States of North America are imported spirits, soap, sperm candles, dried and salt provisions, tobacco, furniture, and deals. Some years ago great quantities of flour and coarse unbleached cotton-cloth were imported from these parts, but very little is now brought. Brazil sends to Buenos Ayres tobacco, sugar, coffee, and rice; and a great quantity of the maté, or Paraguay tea, of an inferior description. From China are brought in British vessels tea, silks, crapes, nankeens, wearing-apparel, tortoise-shell, earthenware, matting, and some minor articles. Havanna sends to Buenos Ayres sugar, coffee, and tobacco.

Exports from Buenos Ayres in 1822, 1829, and 1837.

Articles.	Value in 1822. Dollars.	Value in 1829. Dollars.	Value in 1837. Dollars.
Silver, coined and bullion	1,115,153	291,173	277,791

Mules are occasionally exported to the West Indies and to the island of Mauritius. All the articles which occur in the above list are brought to Europe—except the jerked beef, which goes to the Spanish West Indies and Brazil; the corn and flour, which are exported to the last-mentioned country; and a considerable portion of wool and sheep-skins, which are carried to the United States of North America.

The average number of vessels which annually enter the port of Buenos Ayres is 240. In 1837 only 228 entered, and of this number 61 were British, 40 from the United States of North America, 42 from Brazil, 24 from France, 20 from the ports of the kingdom of Sardinia, 12 from Spain, 9 from Denmark, 7 from Hamburg, 4 from Sweden, 4 from Bremen, 2 from Portugal, and Tuscany, Holland, and Russia sent each one.

As the produce of the central and northern provinces is carried by land to Montè Video, and thence exported to foreign countries, we shall add the articles exported from that harbour, observing that the republic of Uraguay, of which Monte Video is the only commercial port, supplied probably less than one-fourth of the exported goods.

Table of exports from Monte Video in 1836, showing the quantities of each article, and the countries for which they were shipped:—

	England.	France.	United States.	Spain.	Sardinia.	Antwerp.	Brazil.	Havanna.	Total Quantity

More copious particulars on the commerce of the Argentine Republic are given in Sir Woodbine Parish's valuable book on Buenos Ayres and the provinces of the Rio de la Plata, from which these statistical facts are taken.

History.—Though Amerigo Vespucci sailed along the coast before the end of the fifteenth century, it does not appear that he observed the wide æstuary of the Rio de la Plata. It was discovered by Juan Diaz de Solis, who was sent to these parts in 1512, by the Spanish government, and he took possession of it, but did not form a settlement.

Sebastian Cabot was sent from Spain, in 1530, to make discoveries in South America. He traversed the La Plata, and following the course of the Rio Paraná to its confluence with the Paraguay, sailed up the first-mentioned river, but being prevented from proceeding far by shoals and cataracts, he entered the Paraguay, which he ascended to a point above the place where Asuncion is situated. He built also a small fort at the place where the Rio Tercero, or rather the Carcarañal, joins the Paraná (32° 30′ S. lat.), which he called Santo Spiritu, which however was destroyed by the Indians soon after his departure. The favourable account that he gave of the country called Paraguay induced the Spaniards to send a considerable force to these parts under the Adelantado Don Pedro de Mendoza, in 1534, who built a fort near the spot on which the town of Buenos Ayres now stands; and he then sailed to Paraguay to found the town of Asuncion. The fort was soon destroyed by the Indians. The Spaniards concentrated their forces in Paraguay, and from thence they gradually began to establish their settlements over the country.

In 1573, Don Juan de Garay founded the town of Santa Fé. In the mean time other Spaniards, who, for some time before had held undisturbed possession of Alto Peru, or the present republic of Bolivia, advanced southward, passed the Abra de Cortaderas, and founded Salta, Tucuman, and Cordova, about the same time that Garay built Santa Fé. The town of Buenos Ayres was founded by Garay in 1580. He built a fort sufficiently strong to repel the attacks of the Indians. All the countries thus conquered were joined to the viceroyalty of Peru, of which they formed a portion until 1777, when Buenos Ayres was divided from it, and constituted a separate viceroyalty. In the seventeenth century the Jesuits entered the country for the purpose of civilising the Indians and converting them to Christianity. Their progress was at first slow, but after the year 1692, when they obtained more extensive privileges, the conversion and civilisation of the Guaranis, who inhabited both banks of the Paraná above the island of Apipé, went on rapidly; and about the middle of the last century it was stated and believed that the Jesuits had succeeded in forming a powerful state. On the suppression of the Jesuits in 1768, it was found that the country was inhabited by about 100,000 peaceful and industrious Guaranis. Since that time the Missiones, as they are called, have rapidly decreased in population. At present the number of the inhabitants is stated to be under 8000. Though the attempts to convert the other tribes who inhabit the northern provinces were not attended with great success, the Spaniards had suffered less from their incursions than from the attacks of the southern tribes, who, from the time that they had obtained horses, adopted the habits of the Mongols and other nomadic nations of Upper Asia, and by their unexpected incursions laid waste the neighbouring Spanish settlements, and drove off their herds of cattle. If these natives had submitted to the orders of the hereditary chiefs, like the Mongols, they would probably have expelled the whites from the plains and confined them to the mountainous regions. The Spaniards tried all means to bring about a pacification, and they partly succeeded in 1740, when the course of the Rio Salado of Buenos Ayres and the parallel of 35° S. lat. were agreed upon as the boundary between the southern Indians and the Spanish settlements.

In 1805 the town of Buenos Ayres was taken by the British, but they were soon expelled. The inhabitants of the Argentine Republic, like those of the other Spanish colonies, did not submit to the authority of Joseph Bonaparte, and, in 1810, they organised an independent government in the name of king Ferdinand VII. But after Ferdinand recovered the throne of Spain, his measures respecting the American colonies created such disgust, that the states united and declared their independence in the town of San Miguel de Tucuman, the 9th of July, 1816; and in 1819, a federal government was projected, but the states refused to accede to it because they were made too dependent on the federal government. At the same time disunion and civil war broke out, which were attended by a rapid succession of political changes. The provincial government of Buenos Ayres underwent twenty changes between the 10th of November, 1819, and the end of January, 1821. In 1821 the government seemed to have acquired some consistency, at least at Buenos Ayres. But the ascendancy which the military acquired in the war with Brazil, brought on other revolutions after the conclusion of peace (1828), which continued until 1836, when Rosas was created dictator for life. At present the French have declared war against Buenos Ayres, and are blockading the port.

Journal*, vol. ix.; Head's *Rough Notes taken during some Journeys across the Pampas and among the Andes.*)

PLATÆA, or PLATÆÆ, was a city of Bœotia under the ridge of Mount Cithæron, about 60 stadia, or rather more than 7 miles, south-west of Thebes. The river Asopus ran between, at nearly an equal distance from each. The Bœotians, who migrated from Arne in Thessaly, did not colonise Platæa until after they had occupied the rest of Bœotia (Thucyd., iii. 61); and it was from the first distinguished by a spirit of resistance to Thebes in her assertion of supremacy over the neighbouring country. The Platæans in fact were resolved to maintain their independence, and the Thebans were determined if possible to reduce them to the same condition as the other Bœotians. To prevent this, Platæa allied herself with Athens, the Lacedæmonians having referred them to that state as more capable of affording them assistance than themselves (B.C. 519). This connection appears to have determined the fortunes and conduct of the Platæans in succeeding times, for they were the allies of Athens at the battles of Marathon, Artemisium, and Platæa (B.C. 479), when the rest of the Bœotians joined the Persians, and also in the Peloponnesian War. One of the first events of this war was the unsuccessful seizure of Platæa by the Thebans, and one of the most remarkable was the siege of the same city by the Lacedæmonians, on the refusal of the inhabitants to give up their alliance with the Athenians. They held out to the last extremity, and on their surrender were put to death by the Lacedæmonians to the number of 200, the rest having escaped by a sortie in the night. This was done at the instigation of the Thebans (B.C. 427), who afterwards razed the city to the ground. The citizens were subsequently (B.C. 386) restored, in the year after the peace of Antalcides. (Paus., ix. 1, 3.) The city was however again destroyed by the Thebans, in B.C. 374 (Clinton's *Fast. Hell.*); and though Philip of Macedon promised to rebuild it, and its restoration was proposed on the capture of Thebes (B.C. 335) by Alexander, the final restoration of the Platæans was not effected till B.C. 315, sixty years after their last expulsion by the Thebans. (Clinton's *Fast. Hell.*, ii., p. 396.)

PLATA'LEA, the generic name by which Linnæus designates the *Spoonbills*. [HERONS, vol. xii., p. 167.]

PLATANTHE'RA is a genus of Orchidaceous plants, struck off Habenaria on account of the stigmatic processes of the column being small and inconspicuous, or altogether obsolete, instead of being lengthened into horn-like projections below the arms of the anther. The species are numerous, and inhabit the temperate parts of the Old World, but are rarely ornamental, and never of any known use. The 'British Flora' comprehends two species, *P. bifolia* and *P. chlorantha*, both white flowered, and called *Butterfly Orchis.*

PLA'TANUS. [PLANE.]

PLA'TINA, or PLA'TINUM, an important metal, although is was not known earlier than about the middle of the last century. It was first made known in Europe by Mr. Wood, assay-master in Jamaica, who met with its ore in 1741. In 1750 he published a paper upon it in the 'Philosophical Transactions.'

The name of this metal is the diminutive of *plata*, silver, given to it on account of its colour, and it was originally called *platina del Pinto*, because it was found in the auriferous sand of the river Pinto. It has since been found in Brazil, Columbia, St. Domingo, and in the Uralian Mountains.

Platina is separated from the sand and other matters with which it is mixed, by washing with a great quantity of water, from which the heavier parts of course subside, and these contain the ore in question.

The ore of platina is composed of irregular rounded grains, which are sometimes flattened; they are of various sizes, often very small, and occasionally they exhibit traces of crystallization; but these are probably derived from the presence of some other metal. These grains possess no cleavage. Fracture hackly. Hardness 4·0 to 4·5. Specific gravity 17·332. Opaque. Lustre metallic. Colour steel grey.

Berzelius has analyzed many varieties of this ore, from which we select two examples: (1) the ore of Barbacoas, in the province of Antioquia, Colombia, and (2) that of Goroblagodat in Siberia;—

	(1)	(2)
Platina	84·30	86·50
Palladium	1·06	1·00
Rhodium	3·46	1·15
Iridium	1·46	..
Osmium	1·03	..
Iron	5·31	8·32
Copper	·74	·45
Gangue	·60	1·40
	97·96	98·82

The process of purifying platina and of rendering it malleable is one of considerable complication and difficulty, and it is one which our space will not permit us to detail; we therefore merely refer to the late Dr. Wollaston's extremely interesting paper on the subject, contained in the 'Philosophical Transactions' for 1829.

The following are the properties of pure platina:—its colour is greyish-white, intermediate between silver and tin. When it is free from iridium, it is so very ductile, that it may be drawn into very fine wire, not exceeding the 2000th part of an inch in diameter; it is also very malleable, and may be beaten into thin leaves. According to Berzelius, when perfectly pure, it is softer than silver, and it is susceptible of receiving a fine polish. Of all metals it is the least expansible. Its density varies: when fused, it is 19·50; when forged, it is as high as 21·4 to 21·5.

Platina suffers no change by exposure to the air, nor is it oxidized when heated in it. It does not under any circumstances decompose water. It is infusible in the strongest heat of a smith's forge, but it may be melted by voltaic electricity or by the oxyhydrogen blowpipe. Of all metals, except iron and copper, it is the most tenacious: a wire of the diameter of 0·787th of a line is capable of sustaining a weight of about 274 pounds. Like iron, platina possesses the very valuable property of welding at a high temperature, and this enables us to form it into chemical vessels of great and daily use.

Oxygen and Platina, it follows from what has been already stated, have but little affinity for each other. It is not acted upon, and consequently is not oxidized, by the agency of any acid whatever; but when it is treated with nitro-hydrochloric acid (aqua regia), it is converted into a chloride, and when the protochloride is digested with heat in a solution of potash, a black oxide, or protoxide, is formed, part of which is dissolved by the excess of alkali, and part is precipitated; when sulphuric acid is added to the alkaline solution to saturation, the oxide of platina which it held in solution is precipitated of a greenish colour. It is a hydrate, which, when heated, first loses water and afterwards oxygen, and is reduced to the metallic state.

Protoxide of Platina is nearly black, very bulky, and has a good deal the appearance of charcoal. It decomposes readily and even with detonation at a heat below redness. It is soluble in sulphuric acid and hydrochloric acid, and in its nascent state some vegetable acids dissolve it. It is easily reduced by combustible bodies. The salts which it forms with acids are but little permanent, it being separated readily into metallic platina and peroxide.

It consists nearly of

One equivalent of oxygen	8
One equivalent of platina	98
Equivalent	106

Sesquioxide of Platina.—According to Mr. E. Dury, when sulphate of platina is decomposed by ammonia, and the precipitate boiled in a weak solution of potash, and then cautiously dried, *fulminating platina* is formed, which, when treated with nitric acid, leaves a grey powder, which is a sesquioxide, composed of

One and a half equivalents of oxygen	12
One equivalent of platina	98
Equivalent	110

It is also stated that this oxide may be obtained by heating *spongy platina* with potash, and then treating the residue with dilute nitric acid.

Binoxide of Platina may be prepared by precipitating sulphate or nitrate of platina with potash, and keeping the portions separate. The first is a hydrate of the peroxide, and the last a subsalt. The hydrate is to be moderately heated, so as to expel the water, but not any of the oxygen: the hydrate of this oxide is yellow, but when the water is expelled it becomes black.

It combines with most acids, and forms salts, which are brown or red; it has however a greater tendency to combine with alkalis and oxides than with acids.

It is composed of

Two equivalents of oxygen	16
One equivalent of platina	98
Equivalent	114

Chlorine and Platina do not act upon each other, unless the chlorine be in the nascent state, for if the metal be exposed to the gas even at red heat, or in solution in water, no action takes place between them, but the

Protochloride of Platina may be obtained by dissolving the metal in aqua-regia, or nitro-hydrochloric acid; in this case the nascent chlorine dissolves it, and by evaporating the solution to dryness, and exposing the residue to a heat of about 392°, until chlorine ceases to be evolved, the protochloride remains. This chloride is green, unalterable in the air, insoluble in water, or in sulphuric or nitric acid, but hydrochloric acid partially dissolves it, and the solution is red. At a high temperature it is totally decomposed, the chlorine being expelled, and metallic platina left. The caustic alkalis, potash and soda, decompose it, and separate protoxide of platina, which dissolves in an excess of the alkalis, and yields a deep green-coloured solution.

It is composed of—

One equivalent of chlorine	36
One equivalent of platina	98
Equivalent	134

Bichloride of Platina is obtained by evaporating a solution of platina in nitro-hydrochloric acid to dryness at a very gentle heat, when it remains as a red hydrate, which becomes brown when the water is expelled. This salt is deliquescent; very soluble in water, alcohol, and æther; the solutions which it forms are of a pure yellow colour; light decomposes them, metallic platina being deposited. When the solution contains excess of hydrochloric acid, orange yellow crystals are obtained, which are considered as a hydrochlorate of the bichloride; when subjected to a moderate degree of heat, the bichloride becomes protochloride, and at a red heat it is totally decomposed, chlorine being expelled, and metallic platina left.

It is composed of—

Two equivalents of chlorine	72
One equivalent of platina	98
Equivalent	170

Bromide of Platina is obtained by dissolving platina in a mixture of hydrobromic and nitric acids. It is of a reddish-brown colour and becomes a crystalline mass by evaporation. It is decomposed by heat. It is probably a bibromide, composed of—

Two equivalents of bromine	156
One equivalent of platina	98
Equivalent	254

Carbon and Platina have lately been combined by Zeise; they form a black powder, which is composed of—

Two equivalents of carbon	12
One equivalent of platina	98
Equivalent	110

Sulphur and Platina form two compounds: the

Protosulphuret of Platina may be formed by several processes, as by heating these elements together in an exhausted glass tube, or heating the ammonio-chloride of platina with half its weight of sulphur until the hydrochlorate of ammonia and excess of sulphur are entirely expelled; or by adding hydrosulphuric acid to protochloride of platina.

It is a grey or blackish powder of a metallic lustre, unaltered by exposure to air or water, and scarcely attacked even by boiling acids, but is decomposed when ignited with chlorate of potash. It consists of—

One equivalent of sulphur	16
One equivalent of platina	98
Equivalent	114

Bisulphuret of Platina is procured by mixing a solution of sulphuret of potassium with one of chloride of platina; the precipitated sulphuret is a black powder, which is to be dried in vacuo over sulphuric acid.

When it is exposed to dry on paper in the air, the sulphur absorbs oxygen, and becomes sulphuric acid, which acts upon and chars the paper.

It is formed of—

Two equivalents of sulphur .	32
One equivalent of platina . .	98
Equivalent . .	130

Phosphuret of Platina is prepared by subjecting spongy platina to the action of phosphorus: it is hard, brittle, of a silvery white colour, has a crystalline fracture, and is more fusible than silver; it is partially decomposed by heat, and completely so by roasting.

Iodine and Platina may be combined.

Protiodide of Platina is obtained by decomposing a solution of the protochloride with one of iodide of potassium: after the mixture has been for some time heated, a black, heavy, finely divided precipitate is obtained, which adheres to the fingers like charcoal; it has neither taste nor smell; is unalterable in the air, and neither water nor alcohol acts upon it at any temperature. It may be heated to above 482° Fahr. without decomposing, but at the heat of boiling mercury the vapour of iodine begins to rise, and at a still higher temperature it is entirely decomposed, spongy platina remaining. It is not acted upon by acids even when heated, but it is gradually decomposed by a solution of potash or soda.

It is composed of nearly

One equivalent of iodine . .	126
One equivalent of platina .	98
Equivalent . .	224

Bi-iodide of Platina is readily formed by mixing solutions of iodide of potassium and bichloride of platina; a crystalline black powder is precipitated on the application of heat, which, after washing with boiling-water, is to be dried in vacuo over sulphuric acid or by a water-bath. It is inodorous, insipid, and stains the fingers like the protiodide, and is not acted upon by boiling water, but is decomposed at a temperature of about 268°. It is soluble in cold alcohol, but more readily so in hot, and the solution is of a greenish-yellow colour, and not decomposed by water. Cold sulphuric acid does not act upon it, but when they are heated together, a portion of iodine is expelled.

It is composed of—

Two equivalents of iodine .	252
One equivalent of platina .	98
Equivalent . .	350

Boruret of Platina is obtained by fusing spongy platina with boracic acid and charcoal; the compound is hard, and slightly crystalline; when dissolved in aqua-regia, it yields chloride of platina and boracic acid.

Seleniuret of Platina. Spongy platina combines with selenium, with the evolution of much heat; it is a grey powder, which by exposure to heat and air is decomposed, the selenium evaporating, and the metal being left. Platina crucibles are acted upon by compounds of selenium, when the latter are heated in them.

Siliciuret of Platina is formed when platina is heated with charcoal in an earthen crucible: the silicium is yielded both by the earthy matter of the charcoal and of the crucible. A compound thus obtained was found by Berzelius to have a specific gravity of 13·3; it was granular and very hard; when put into aqua-regia, it was acted upon, and soon covered with a sufficient crust of silica to retard the action of the solvent.

The principal binary compounds of platina and non-metallic elements having now been described, we shall give a brief account of the more important binary compounds which its forms with the metals, or the

ALLOYS OF PLATINA. Most metals combine with platina, but little is known of its compounds with the metals of the alkalis and earths. According to Berzelius, potassium has considerable affinity for it, and they unite at a high temperature. When the alloy is treated with water, it is decomposed, and black scales are formed, which are composed of hydrogen and platina.

Arsenic and Platina readily unite: an alloy formed of 20 parts of the former metal and two of the latter is of a greyish-white colour, very brittle, fusible at rather above a red heat, is not acted upon by the air at common temperatures, but when it is heated it absorbs oxygen from the air, and is converted into arsenious acid, which is volatilized, and metallic platina remains. Jeannetty of Paris long employed this process for extracting platina from the native grains, and rendering it useful for crucibles, &c.

Antimony and Platina during combination evolve much light. This alloy is very brittle, fine-grained, and hard. It is decomposed at a high temperature, the antimony being oxidized and expelled.

Zinc and Platina form an alloy of a greyish-blue colour; it is so brittle that it is easily reduced to powder. At a high temperature the zinc burns, and a large proportion, but not the whole of it, is volatilized.

Tin and Platina yield an amalgam which is large-grained, brittle, and hard. The presence of a small quantity of platina is sufficient to destroy the malleability of tin.

Iron and Platina. Iron and steel render platina more fusible. Faraday and Stodart have examined the alloys of platina and steel, which appear to combine in all proportions. The alloys which contained from 1 to 3 per cent. of platina seemed best adapted for cutting instruments. When equal weights of the two metals are combined, a fine, hard, brilliant alloy of specific gravity 9·862 is obtained; it takes a fine polish, does not tarnish, and appears to be well adapted for mirrors; when 80 parts of platina are combined with 20 parts of steel, the alloy has a specific gravity of 15·88.

Nickel and Platina, combined in equal weights, form a pale yellow alloy, susceptible of a high polish, and obedient to the magnet.

Cobalt and Platina form a fusible alloy.

Copper and Platina combine in all proportions, and form alloys which are ductile or brittle, yellow or white, according to the relative quantities used. The colour of copper is diminished by platina.

Bismuth and Platina form brittle alloys, which are not entirely decomposed by cupellation.

Silver and Platina form alloys in all proportions; their colour is intermediate as to that of the metals. They are fusible and ductile, if the silver be in the larger proportion. Like the alloys of platina and iron, those of platina and silver are completely soluble in nitric acid, when there is a sufficient quantity of silver; they are also attacked by sulphuric acid, which dissolves the silver.

Lead and Platina readily combine, with the evolution of light. The affinity of these metals for each other is great, so that if platina and lead foil be rolled together, and one end of the roll be ignited, the mass becomes so strongly heated that it is dissipated in all directions.

Mercury and Platina amalgamate with difficulty; it is effected by exposing spongy platina and mercury to a high temperature. Mercury, when the amalgam consists of 37 platina and 63 mercury, is at first soft, but becomes eventually hard.

Gold and Platina combine in all proportions, and form fusible alloys. Platina destroys the colour of gold, even when it constitutes only 0·02 of the weight of the alloy.

Iridium and Platina. This alloy is perfectly malleable when the former metal amounts to only one or two per cent.; it is much harder than pure platina, and resists the action of heat and chemical re-agents much better than mere platina, and is particularly adapted for chemical vessels. A larger proportion of iridium renders the alloy so brittle that it cracks under the hammer.

SALTS OF PLATINA, or oxysalts, consist of acids and the oxides of the metal: they are not numerous, and have been but imperfectly examined.

Salts of the Protoxide. These are of an olive-green or greenish brown colour, and they are soluble in an excess of alkali, which renders them green; they are not decomposed by hydrochlorate of ammonia.

Salts of the Peroxide are yellowish-red or brownish-red; most of them are soluble in water, and perfectly decomposed at a white heat, leaving metallic platina; and there is thus obtained the metal in that finely divided state in which it is called *spongy platina.* These salts are precipitated by zinc, iron, and copper, and give a black precipitate of sulphuret of platina with hydrosulphuric acid and hydrosulphates.

The alkalis decompose these salts but imperfectly, on account of the formation of double subsalts. Protochloride of tin occasions no precipitate, but the solution becomes of a very characteristic and intense red colour.

Protosulphate of Platina is formed by adding the protoxide to the acid. It is a soluble salt, black or reddish, and which eventually becomes converted into persulphate and metallic platina.

Protonitrate of Platina is obtained by dissolving the protoxide in nitric acid; its properties are similar to those of the protosulphate.

Persulphate of Platina is procured by treating the bisulphuret with nitric acid. It is black, and may be combined with the alkaline sulphates, and it yields insoluble double subsalts when decomposed by the alkalis.

Pernitrate of Platina is of a deep brown colour, and is prepared by dissolving the peroxide in the acid; by evaporation it is easily converted into a subsalt, and double subsalts are formed when it is decomposed by the alkalis.

A numerous class of double salts, called *platino-chlorides*, have been formed and examined; they are obtained by adding the chlorides of potassium, sodium, &c., and hydrochlorate of ammonia, to the chlorides of platina; some are soluble and others are insoluble in water.

Mr. Brande gives the following statement of the

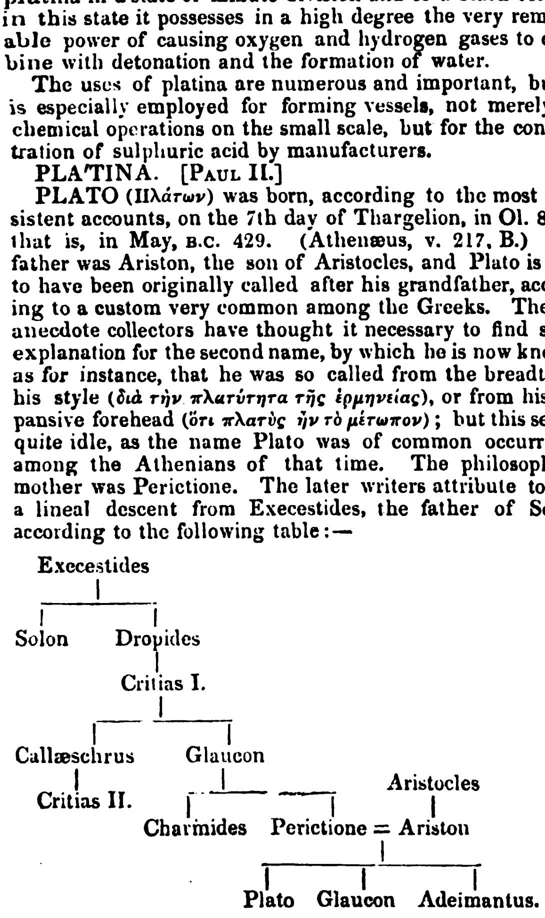
Characters of the Salts of Platina.—'The difficult solubility of the ammonio- and potassio-chlorides of platina, and the solubility of the corresponding sodium compounds, are very characteristic of this metal. Phosphate of soda produces no precipitate in chloride of platina; the ferrocyanide of potassium throws down the platino-chloride of potassium; cyanide of mercury occasions no precipitate; iodide of potassium communicates a reddish-brown colour to solutions of the chlorides of platina, and gradually produces a brown precipitate; and if the mixture be heated in a matrass, the glass acquires a strong coating of metallic platina. All the metals which reduce the chloride of gold, with the exception of palladium, act similarly upon chloride of platina, but its complete separation in the metallic state is slow: iron, zinc, cadmium, and copper are its most effective precipitants; they separate it in a black powder, which sometimes adheres in films to the glass.'

Tartrate of soda added to and heated with a solution of chloride of platina is a very effective precipitant of metallic platina in a state of minute division and of a black colour; in this state it possesses in a high degree the very remarkable power of causing oxygen and hydrogen gases to combine with detonation and the formation of water.

The uses of platina are numerous and important, but it is especially employed for forming vessels, not merely for chemical operations on the small scale, but for the concentration of sulphuric acid by manufacturers.

PLATINA. [PAUL II.]

PLATO (Πλάτων) was born, according to the most consistent accounts, on the 7th day of Thargelion, in Ol. 87, 3, that is, in May, B.C. 429. (Athenæus, v. 217, B.) His father was Ariston, the son of Aristocles, and Plato is said to have been originally called after his grandfather, according to a custom very common among the Greeks. The old anecdote collectors have thought it necessary to find some explanation for the second name, by which he is now known, as for instance, that he was so called from the breadth of his style (*διὰ τὴν πλατύτητα τῆς ἑρμηνείας*), or from his expansive forehead (*ὅτι πλατὺς ἦν τὸ μέτωπον*); but this seems quite idle, as the name Plato was of common occurrence among the Athenians of that time. The philosopher's mother was Perictione. The later writers attribute to her a lineal descent from Execestides, the father of Solon, according to the following table:—



It seems doubtful, however, whether Solon and Dropides were really brothers; that they were intimate friends and connections appears from the words of Plato himself in the *Timæus* (p. 20, E)[*]; but perhaps the claim of a direct descent from Execestides originated only in later times, when the admirers of the great philosopher lost no opportunity of exalting his family and investing his early youth with the wonders of fable. It is also stated that he was born in the island of Ægina, which was, about the time of Plato's birth, stripped of its inhabitants, and occupied by Athenian colonists (*κληροῦχοι*), among whom was Aristophanes, the comic poet.

As might have been expected from his connection with the most distinguished Athenian family, Plato received the best education that Athens could furnish: Dionysius taught him reading and writing (*γράμματα*); he was instructed in gymnastic exercises by an Argive wrestler named Ariston; his masters in music were Metellus of Agrigentum, and Draco of Athens, a pupil of the celebrated Damon. He was sufficiently skilled in wrestling to contend at the Pythian and Isthmian games, and his first literary attempts, the composition of dithyrambic, lyric, and tragic poems, show that he had profited by the instruction of his music-masters. He is also said to have applied himself to painting.

Plato's connection with Socrates is said to have commenced in B.C. 410. He had previously, and while very young, learned the doctrines of the Heracleitean philosophy from Cratylus (Aristot., *Metaphys.*, i., c. 6: *ἐκ νέου συγγενόμενος πρῶτον Κρατύλῳ καὶ ταῖς Ἡρακλειτείαις δόξαις*; Apuleus, *De Dogm. Plat.*, p. 2: *et antea quidem Heracliti secta fuerat imbutus*), who appears to have been a friend or acquaintance of Socrates. (Plato, *Cratyl.*, p. 430, C.) The assertion of Diogenes Laertius (iii. 6) that he learned the Eleatic doctrines from Hermogenes seems to be derived from this statement with regard to Cratylus, and from the circumstance that Hermogenes maintains the Eleatic opinions against Cratylus in the dialogue which bears the name of the latter.

On the death of Socrates (in May, B.C. 399), Plato betook himself to Megara, in company with several of his late master's followers. Related as he was to Critias and Charmides, who fell fighting side by side against Thrasybulus and his party, and professing, as he always did, sentiments harmonising rather with the oligarchical faction at Athens than with those of the truer patriots who wished for a restoration of the older constitution under which Athens had so long and so pre-eminently distinguished herself, it cannot be doubted that he was driven to this self-banishment from a fear for his own safety; and we shall be the more inclined to draw this inference when we recollect how intimately the prosecution of Socrates was connected with that reaction against the Thirty Tyrants and their supporters in which Lysias took so prominent a part. [SOCRATES.] We are not disposed to charge Plato, at this or at any other time of his life, with absolute treason against the liberties of his country; we are inclined however to hold with Niebuhr (*Kleine Schriften*, p. 476; *Philol. Mus.*, i., p. 494), that Plato may have been prejudiced against his native city in its constitutional form of government by the warm feelings of his youthful heart; 'but it is not the less true,' adds the historian, 'that, if so, he was not a good citizen.' While at Megara, he is said to have attended the lectures of Euclid, who was the head of a school there [EUCLID], and we find traces in several of his dialogues of an acquaintance with the peculiar doctrines of the Megaric philosophy. He afterwards went to Cyrene to visit Theodorus, the mathematician, who is introduced in the 'Theætetus' as living at Athens before the death of Socrates, and advocating the doctrines of Protagoras against that philosopher. From thence, we are told, he travelled to Egypt, where he spent thirteen years, collecting all the traditions which the priests could teach him; and it is said that he afterwards went to Persia to learn the doctrines of the Magi, and even became acquainted with the laws and religion of the Jews. (Lactant., *Institut.*, iv. 2; Clemens Alexandr., *Protrept.*, p. 46, A.) So late as in Strabo's time the traveller to Heliopolis was shown the house where Plato and his companion Eudoxus had lodged. (Strabo, p. 806, C.) That Plato visited Egypt is also stated by Cicero, in a remarkable passage (*De Republ.*, i. 10), and the story is not in itself improbable, especially if we admit the truth of his journey to Cyrene; it seems however exceedingly unlikely that he resided there so long as thirteen years, for he never speaks of Egypt like a person who was familiarly acquainted with the peculiarities of the country, and his philosophy was so much cultivated at Alexandria in later times, that a lie circumstantial, like that which Strabo relates, might easily have been fabricated on the spot. The other exaggerations with regard to Plato's travels in the East are highly absurd, and can only be accounted for from the great importance attributed to his philosophy by the early Christian writers, and by their wish to make out that the apparent coincidences between his system and the Christian revelation were not anticipations so much as proofs of his acquaintance with the traditions and prophecies of the East. There is probably more truth in the statement that, on his return from Egypt, he went to Tarentum to visit or renew his acquaintance with some renowned teachers of the Pythagorean school; he certainly did not go to Italy to learn the doctrines of this school; he might have learned them nearer home, for the celebrated Pythagorean Philolaus had been at Thebes before the death of Socrates; Cebes and Simmias heard him there (Cicero, *De Fin.*, v. 29; Diog. Laert., viii. 46); and Plato shows in his earliest works that he was not unacquainted with the tenets of the Pythagoreans.

---

[*] Critias is here made to say of Solon, *ἦν μὲν οὖν οἰκεῖος καὶ σφόδρα φίλος ἡμῖν Δρωπίδου τοῦ προπάππου*: and the scholiast on the passage says, *λέγονται γὰρ οἰκεῖοι καὶ οἱ συγγενεῖς.*

This journey to Magna Græcia seems to be connected with the first of three visits which he paid to Sicily. Curiosity to see an eruption of Mount Ætna is said to have been the motive for this first voyage to Syracuse, which, it is stated, he undertook in the fortieth year of his age, therefore in B.C. 389. (Athen., xi., p. 507, B; Diod. Sic., xv. 7; Pseudo-Plat., *Epist.* vii., p. 324, A.) It was on this occasion that he became acquainted with Dionysius I., tyrant of Syracuse; with his son, Dionysius II.; and with Dion, brother-in-law of the former and uncle of the latter. He had the misfortune to offend the elder Dionysius by some freedom of speech; and the tyrant got Pollis, the Spartan ambassador, in whose ship he was returning to Greece, to sell him at Ægina as a slave. He was bought by Anniceris of Cyrene, who gave him his freedom; and, on returning to Athens, he set up a school in the Academy, where he taught for twenty-two years. After this he paid a second visit to Syracuse, at the request of Dion, to endeavour to form by philosophical instruction the ill-educated mind of his nephew, the younger Dionysius. He failed in doing this; and Dion being banished soon after, Plato returned to Athens with the tyrant's permission. This second journey is placed in B.C. 367, and Plato stayed four months in Sicily. His third journey to Sicily is placed in B.C. 361; it seems to have been undertaken in the hope of reconciling Dion and Dionysius. Plato's stay at the tyrant's court became disagreeable and dangerous to himself, and it was not without difficulty that he obtained permission to return again to Athens, which he did in the following year. In B.C. 357 Dion collected an expedition in Greece for the purpose of liberating Syracuse from the tyranny of Dionysius: among the volunteers who joined this expedition was Speusippus, a nephew of Plato, who had accompanied him on his second journey to Sicily. Dion succeeded in his object, but was soon after murdered (B.C. 353), and with his death Plato's connection with Syracuse ceased.

Plato spent the last years of his life in the diligent prosecution of his philosophical and literary pursuits. Cicero tells us (*De Senect.*, c. 5) that he was actually engaged in writing at the moment of his death. His lectures were at first delivered in the garden of the Academy itself, but afterwards in a garden which he had bought, near the Academy, and between it and the village Colonus. Plato died in Ol. 108, 1 (B.C. 347), and was succeeded as lecturer in the Academy by his nephew Speusippus, though he had left Heracleides of Pontus, another of his disciples, as his deputy there, when he took Speusippus with him on his second journey to Sicily.

The following is the list of his scholars as given by Diogenes of Laërte:—Speusippus, Hippothales, and Callippus of Athens; Xenocrates of Chalcedon; Aristotle of Stagira; Heracleides of Pontus; Philippus of Opus; Hestiæus of Perinthus; Dion of Syracuse; Amyclus of Heracleia; Erastus and Coriscus of Scepsis; Timolaus of Cyzicus; Evæon of Lampsacus; Pithon and Heracleides of Ænus; and Demetrius of Amphipolis; to which list some added the Athenian orators Demosthenes, Hyperides, and Lycurgus, and the philosopher Theophrastus. See also the contradictory lists of tyrants and good statesmen who proceeded from the school of Plato, in Athenæus, xi., p. 508, fol.; and Plutarch, *Adv. Colot.*, p. 1126.

The works of Plato consist of a long series of dialogues, in all of which, excepting the 'Laws,' the principal interlocutor is Socrates. The form of the dialogue was not first introduced by Plato. He is said to have been preceded in that species of composition by Alexamenus of Teos and by Zeno of Elea. Of the former, Aristotle (in the first book of his 'Treatise on Poets,' as quoted by Athenæus, xi., p. 505, C) says, 'We cannot deny the name of discourses and imitations to the mimes of Sophron and to the dialogues of Alexamenus of Teos, which were *the first written of the Socratic dialogues.*' With regard to the statement about Zeno, it must be admitted that it rests upon a very uncertain basis. Diogenes only says, vaguely, '*They say* that Zeno of Elea was the first who wrote dialogues' (διαλόγους τοίνυν φασὶ πρῶτον γράψαι Ζήνωνα τὸν Ἐλεάτην), and Aristotle describes him as 'the answering and questioning Zeno' (ὁ ἀποκρινόμενος καὶ ὁ ἐρωτῶν Ζήνων: *Sophist. Elench.*, c. 10, sec. 2). It is more probable that Plato's adoption of the form of dialogue resulted rather from the nature of the case than from any direct imitation. The spirit of the dialectics of the Eleatic school, with which Plato's philosophy was so strongly imbued, depended mainly on its being in the form of question and answer. The very name 'dialectics' points to this: the word διαλέγεσθαι signifies merely 'to converse,' as appears from the use of the common word dialexis (διάλεξις), 'conversation,' to signify 'dialectics,' in Aristoph., *Nub.*, 317. αἵπερ γνῶμην καὶ διάλεξιν καὶ νοῦν ἡμῖν παρέχουσι; for of course no weight will be attributed to the explanation of the verb which Xenophon puts into the mouth of Socrates (Xen., *Memor.*, iv. 5, sec. 12), an explanation which is obviously derived from its secondary and technical meaning. That Plato then should write in the form of dialogue seems to be the natural consequence of his wish to investigate and analyze, dialectically and after the manner of Socrates, the various questions of philosophy then in vogue. Nor is it at all necessary to suppose that Plato was immediately indebted to any one for the dramatic tone which characterises his dialogues: indications of a real dramatic genius, and of imitative powers of the first class, are scattered so plentifully over all his works, that we cannot fail to recognise everywhere the hand of an artist who copies nature alone. It is not improbable that he studied, and with great profit, both Epicharmus and Sophron: Alcimus, quoted by Diogenes of Laërte (iii. 18), says that he transcribed most of the writings of the former; and according to Quintilian (i. 10, sec. 17), the philosopher was so fond of the mimes of Sophron, that he had a copy of them under his pillow when he died. It seems however likely that he did not become acquainted with the writings of these two authors till his first journey to Magna Græcia and Sicily; and it is certain that several of his dialogues, and some of those in which the dramatic element is most prominent, were composed long before that time, so that he could not have owed anything to them in the first instance.

But though the *form* of Plato's works was not much influenced by his acquaintance with other writers, it is impossible to overlook the fact that, for their *matter, they* were composed with a continual reference to the labours of his predecessors. In fact, Plato's whole system is rather critical and eclectic than dogmatical, and many of his dialogues are rather reviews of the speculations of former philosophers than formal enunciations of any doctrine of his own. The view which he took of philosophy was decidedly a literary one; he was the first of the Greek philosophers who can be considered as a student as well as an expounder of philosophy, as may indeed be inferred from the statement of Heracleides of Pontus, that he was among the first to collect books and import them to Athens. (Proclus, in *Tim.*, i., p. 28; Diog. Laert., viii. 15.) Besides the great ideas and peculiar system of Socrates, which he had learned during his intercourse with that philosopher, Plato was thoroughly conversant with the systems of Pythagoras, Heracleitus, Parmenides, Zeno, Anaxagoras, and Protagoras; his works abound with references to their writings, and some of his dialogues are controversial tracts directed against one or more of these philosophers; nor had he neglected his contemporaries of the Socratic school, some of whom, as Aristippus, Euclid, and Antisthenes, he criticises rather severely. Cicero, in the passage of his treatise 'De Republicâ' (i., c. 10), referred to above, seems to consider that the philosophy of Pythagoras, combined with the dialectics of Socrates, formed the main groundwork of Plato's philosophy: 'On the death of Socrates,' says he, 'Plato first went to Egypt to add to his stock of knowledge, and afterwards travelled to Italy and Sicily in order to learn thoroughly the doctrines of Pythagoras; he had a great deal of intercourse with Archytas of Tarentum and with Timæus the Locrian, and procured the commentaries of Philolaus; and as Pythagoras then enjoyed a great reputation in that part of the world, Plato applied himself to the society of Pythagorean philosophers, and to the study of their system. Accordingly, as he was devotedly attached to Socrates, and wished to put everything into his mouth, he interwove the elegance and subtilty of the Socratic mode of arguing with the obscurity of Pythagoras and the many branches of learning which the Pythagorean philosophy included.' That this is only a partial account of the matter we shall see presently; but Cicero is undoubtedly right in attributing a great deal to the influence of the Pythagorean philosophy on the opinions of Plato. It was from this, no doubt, that Plato was induced to pay so much attention to Epicharmus, who was not only a great comedian, but also a renowned Pythagorean philosopher. (See Clinton's *Fasti Hellenici*, vol. ii., p. xxxvi., note *g*, for the identity of Epicharmus *the philosopher* with Epicharmus *the poet*.) The benefits which Plato derived from a study of Epicharmus are distinctly asserted by Diogenes Laertius (iii. 9-16), and some lines are very pointedly quoted from one of his comedies, in which he prophesies that some future writer would confute and overthrow all opponents by adopting his sayings and clothing them in a different dress. Plato sometimes quotes Epicharmus by name (as in the *Gorgias*, p. 505, D), and in one passage he pays him the high compliment of naming him and Homer as the two chief poets, the one of comedy, the other of tragedy. (*Theætet.*, p. 152, E.) Plato seems to have been also familiar with the works of Empedocles, who stands half-way between the Pythagoreans and the Eleatics, and who, as Mr. Thirlwall suggests (*Hist. of Greece*, ii., p. 139, note), may probably be looked upon as the predecessor of Plato in his eclectic view of philosophy. There is certainly a direct reference to the doctrines of Empedocles in the *Sophistes*, p. 242, D; perhaps also, as Heindorf thinks, in the *Lysis*, p. 214, B, though Stallbaum considers that Anaxagoras is there referred to; and Hermann, in an essay recently published (*Opuscul.*, vol. vii., p. 106), has not hesitated to recognise the very words of Empedocles in a celebrated passage of the *Phædrus*, p. 246, B-C.

On the whole then it is clear that Plato was well acquainted with the labours of his predecessors and contemporaries. But though he may have learned much from them, and though he certainly had borrowed some of his leading views from his great teacher Socrates, we should nevertheless do him great injustice if we regarded him merely as a compiler and systematiser of what had been already advanced, and denied his claim to a place among the originators of great thoughts. Plato's whole system is based upon some grand and novel ideas, which may indeed have been faintly conceived by others, but which were never distinctly uttered and proclaimed till Plato made his appearance. The opposition between the law and the facts, between the general and the particular, between the objects of reflection and the objects of the senses, between the world of intelligence and the visible world, was never clearly pointed out till Plato's time. It is very true that Socrates did awaken the idea of science, and so lay the foundation of dialectics, on which the philosophy of Plato was chiefly built up (see this distinctly stated by Aristotle, *Metaphys.*, xii. 4, § 5); and it is for this reason that Plato has put into the mouth of his master his speculations on this subject. The merit of Plato is that he expressed distinctly and systematically what Socrates only struggled to articulate. The comprehensive view which Plato took of philosophy in all its bearings implied a critical acquaintance with all the branches of his subject and with the works of all his predecessors. From the nature of the case, it was impossible that Socrates should fulfil these previous conditions; he was not and could not have been a literary man, and it does not appear that he was qualified by his character and habits, even if he had possessed the necessary opportunities, to study the systems of other philosophers in an enlightened and critical spirit. The kindred genius of Plato was luckily fostered by every encouraging influence, and he stepped in to elaborate completely the plan of which his master had sketched the rude outline. With many features totally dissimilar, the relation between Socrates and Plato very nearly resembles that between Kepler and Newton; for Kepler's laws stand related to the 'Principia' of Newton much in the same way as the Socratic idea of science does to the dialectical system of Plato. In fact, the case is much the same with every great advance in philosophy; the conception must precede its articulate utterance.

Before we attempt to exhibit the method of Plato's philosophy as it appears in his writings, it will be as well to consider briefly the chronological arrangement of his dialogues, and the natural division according to which they may be classified. Owing to the great admiration in which Plato has been held from his own time down to the present, we have not only a complete collection of his works, but also several dialogues included among them, which, beyond all manner of doubt, were written by some imitators of the great philosopher. Thus, the 'Eryxias' and 'Axiochus' were probably written by Æschines, the Socratic philosopher; the 'Epinomis' by Philip of Opus; and 'The Second Alcibiades' by Xenophon. Leaving out of the question, then, these and other dialogues generally admitted to be spurious, we may divide the genuine dialogues into three classes, which we will arrange in the following chronological order, for reasons most of which have been adduced by Schleiermacher, Ritter, and others, but which our limits will not permit us to enter on in this place. In the first class we would place the dialogues composed by Plato before he set out upon his travels, namely, the 'Lysis,' 'Phædrus,' 'Laches,' 'Hippias major,' 'Protagoras,' 'Charmides,' 'Ion,' 'Meno,' 'Alcibiades I.' 'Euthydemus,' 'Euthyphro,' 'Apology,' and 'Crito.' To the second class we refer those which he wrote after returning from his travels, and before his second journey to Sicily, namely, the 'Gorgias,' 'Theætetus,' 'Sophistes,' 'Politicus,' 'Cratylus,' 'Parmenides,' 'Symposium,' 'Menexenus,' 'Philebus,' 'Phædo,' and perhaps also the 'Republic,' the 'Timæus,' and the 'Critias.' In the third class we place by itself the long dialogue on the 'Laws,' which is but loosely connected with the general system of Plato's works, and seems to be quite an extraneous part of his philosophy. However, notwithstanding this and other dissimilarities, we do not hesitate to recognise in the 'Laws' a genuine work of Plato. It is true that it is the only one of his dialogues in which Socrates does not bear a part; it is true that there is a striking difference of style between the 'Laws' and the other works of Plato; there is in fact a greater difference between the style of the 'Laws' and Plato's ordinary style, than between this last and the style of the epistles, or even than that of the dialogues, which are confessedly spurious; there is a profusion of anacolutha in it to an extent of which we find no example in the other works of Plato: and Ast has objected that the whole plan of the work is inconsistent with Plato's views as developed in the 'Republic.' But with regard to the non-introduction of Socrates, surely no argument of spuriousness can be drawn from this: because Socrates was generally the chief speaker, it was not necessary that he should always be so, and it is probable that the 'Laws' were written with an object totally different from that which Plato generally proposed to himself. With regard to the style, it may be argued, with Cousin, that the 'Laws' had not received the last touches of the author's pen; and it is said that Philippus found the work on the waxen tablets (ἐν κήροις), and copied it out: and with regard to the discrepancies between the 'Laws' and the 'Republic,' Ast seems to have overlooked the distinction which Plato himself has drawn between the two works; for the philosopher says that the second state is not intended to be a perfect one, but only so relatively; besides, the points of discrepancy which have been noticed are not such as to affect any leading principle in Plato's system of ethics; the age fixed for marriage is different in the two works, there is no military caste in the 'Laws,' and the cruel and heartless socialism of the 'Republic' is not mentioned in it: but all these are objections of little weight, and even if they were more difficult to encounter, they would be at once overthrown by the express and positive testimony of Aristotle to the genuineness of the work, and by the internal evidence which must convince every intelligent reader that no man but Plato then living in Greece could have written a treatise at once so comprehensive and so profound. Schleiermacher's arrangement of the works of Plato corresponds in its main features with the one suggested above; it deserves however a separate mention on account of the celebrity of this writer and the important effects which have been produced by his acute and careful examination of the connection of thought running through the dialogues. He also divides them into three classes,—1, elementary dialogues, or those which contain the germs of all that follows, of logic as the instrument of philosophy, and of ideas as its proper object; consequently, of the possibility of the conditions of knowledge; these are the 'Phædrus,' 'Lysis,' 'Protagoras,' 'Laches,' 'Charmides,' 'Euthyphro,' and 'Parmenides,' to which he subjoins, as an appendix, the 'Apologia,' 'Crito,' 'Io,' 'Hippias minor,' 'Hipparchus,' 'Minos,' and 'Alcibiades II.;' 2, progressive dialogues, which treat of the distinction between philosophical and common knowledge in their united application to the two proposed and real sciences, 'Ethics' and 'Physics;' these are the 'Gorgias,' 'Theætetus,' 'Meno,' 'Euthydemus,' 'Cratylus,' 'Sophistes,' 'Politicus,' 'Symposium,' 'Phædo,' and 'Philebus,' with an appendix containing the 'Theages,' 'Erastæ,' 'Alcibiades I.,' 'Menexenus,' 'Hippias major,' and 'Clitophon;' 3, constructive dialogues, in which the practical is completely united with the speculative; these are the 'Republic,' 'Timæus,' and 'Critias,' with an appendix consisting of the 'Laws,' the 'Epistles,' &c. We cannot here enter upon a criticism of this arrangement; we will only remark that we strongly object to Schleiermacher's separation of the 'Theætetus' from the 'Sophistes' and 'Politicus,' which form, with it, a trilogy of dialogues, like the three which are placed together in his third class; and we think that, according to his own principle, as the 'Phædo' is preparatory to the 'Timæus,' and as the 'Philebus,' as an approximate discussion of the idea of the good, is preliminary to the 'Republic,' these two dialogues should occupy the same relative position as the two which they precede. Thus much may suffice for the arrangement of the several dialogues according to some real train of succession. According to their contents, they also form three classes: the Dialectical, Ethical, and Physical dialogues. The formal division of philosophy into these three parts is subsequent to Plato's time, as it was first established by Xenocrates and Aristotle (Sextus Empir., *Adv. Math.*, vii. 16); but Plato certainly had started the idea of such a division, which is distinctly attributed to him by Cicero (*Academ. Post.*, i., c. 5, § 19), and it is clearly discernible in his works, though many of them may not be assignable to any one part in particular: thus the 'Theætetus' and its two connected dialogues are clearly dialectical; the 'Republic' and 'Laws,' ethical; and the 'Timæus,' physical. In endeavouring therefore to give a general view of Plato's philosophical system, we shall adhere to this division, and consider first his views on dialectics, on which his whole system was based, and then his applications of these views to the two provinces of moral and natural philosophy.

I. Plato's system of dialectics is based upon a view of the definition 'real,' which he was the first to bring forwards. The definition, he saw, consists in generalisation and division, i.e. it is made either *per genus* or *per differentiam*. The former process is the base of the second; the second is the development of the former. Consequently, as science, according to Plato, depends upon dialectics, and dialectics on the definition 'real,' in order to general scientific reasoning we must generalise and classify—*κατ' εἴδη σκοπεῖν* and *κατὰ γένος διακρίνειν*. The *ideas* of Plato are, strictly speaking, nothing more than general terms, the main part of the definition 'real,' as Leibnitz calls it, and Plato seems to have constructed his theory of ideas as a mean between the contradictory systems of Heracleitus and the Eleatics. The *Heracleitean* doctrine of a perpetual flux, modified into the dogma of Protagoras, *πάντων μέτρον ἄνθρωπος*,—'The individual man is the standard of all things,'—was directly opposed to Plato's notion of science as based upon an idea or general definition, which is in itself its own ground and authority; for it peremptorily denied *being* (*εἶναι, οὐσία*), and set up in its stead a mere *genesis* or *becoming* (*γίγνεσθαι*), so that nothing could be predicated of any thing as fixed. On the other hand, the *Eleatic* doctrines—1, that all is *one*, and that there is no multiplicity; 2, that all is one immutable being, and that there is no *becoming*, no change, no generation, augmentation, or decay—were equally opposed to Plato's belief in the reality of sensation, for they absolutely denied the *genesis*. Now as Plato was convinced of the reality, both of the permanent being (*οὐσία*), i.e. of the genus signified by the general term, and of the mutable genesis of the phænomena, of the idea as well as of the multiplicity of things, it was necessary that he should form some conception of science which would admit of both. The general science which Plato set forth with this view was called *dialectic*, or the art of conversing, and was based on an examination (the first which had been attempted) of the syntax of the Greek language. In order to make a sentence, to affirm or deny anything, to express a judgment of the mind, it was necessary, he saw, to have at least a *subject* of which something was to be affirmed or denied, and a *predicate* which affirmed or denied something of the subject. This predicate would generally be a verb, but it might be an adjective, as the Greek sentence tolerated an omission of the copula. Words, he says, whether subjects (*ὀνόματα*) or predicates (*ῥήματα*), express neither *entity* (*οὐσία*) nor *action* (*πρᾶξις*), neither *being* nor *becoming*, unless they are joined together in a sentence, and then some tense of *becoming* is predicated of some state of *being*: *δηλοῖ γὰρ ἤδη που τότε περὶ τῶν ὄντων* (the predicates), *ἢ γιγνομένων* (present), *ἢ γεγονότων* (past), *ἢ μελλόντων* (future), *καὶ οὐκ ὀνομάζει μόνον, ἀλλά τι περαίνει συμπλέκων τὰ ῥήματα τοῖς ὀνόμασιν*. (*Sophist.*, p. 262, D.) He speaks here of the mere name of the subject as predicating *being* of it, for we may always predicate *being* of every individual which has a name, in addition to the particular nature which it has (*Sophist.*, p. 251, A); indeed the act of naming or of affixing a general name, the name of the genus, to the individual, is the first step in classification, and in itself gives a fixity to things which is opposed to generation and becoming. (*Theætetus*, p. 157, A.) *Thinking* being the discourse of the soul with itself (*Theætet.*, p. 189, E; *Sophist.*, p. 263, E), and *speech* being a combination of words so as to form discourse for the cognizance of another (*Sophist.*, p. 259, E), thinking is a similar combination of thoughts for the cognizance of a man himself: and thus the science which regulates the combination of thoughts may be called *διαλεκτική*, or the science of discourse. (*Sophist.*, p. 252, E.) It is a science presiding over the faculty which investigates the properties of all sensations. (*Theætet.*, p. 185, B.) This science depends upon definition. Now definition necessarily presumes that some general term should be given, including a multiplicity of objects (*Euthyphr.*, p. 6, D; *Theætet.*, p. 146, D; p. 185, D), and it must then be explained wherein the term to be defined differs from others which belong to the same genus *with* it. (*Euthyphr.*, p. 11, E; *Theætet.*, p. 208, D.) The second process, or the *per differentiam*, is subordinate to the former, which is the all-important one in this science of dialectics.

The great object then of the dialectician is to establish what are those general terms which are the object of the mind when a man thinks. It is clear that they cannot be objects of sense, for these are in a continual state of transition. (*Parmenid.*, p. 152, A.) They must therefore be of the number of those things which we know by means of reflection (*διάνοια*) through the understanding (*λογισμός, νοῦς, νόησις*), for these things being fixed, belong to *οὐσια*, and can become the objects of science or certain knowledge. (*Parmen.*, p. 129, E; *Phæd.*, p. 65, C; *Respubl.* vii., p. 532, A.) Every thing of this kind is an *εἶδος*, that is, a general term. (*Resp.* x., p. 596, A; *Legg.*, x., p. 835-5), or quiddity (*Phædr.*, p. 237, B.) Consequently there is an *idea*, or *εἶδος*, of everything that is called by a general name. Hence the formula for the universal is neither *ἓν* only, as the Eleatics said, nor *πολλά* only, as the Heracleiteans asserted, but *ἓν καὶ πολλά*, 'the one and the many,' i.e. the subject of which many predicates may be asserted, and which therefore appears as manifold. (*Respubl.*, v., p. 476, A; *Sophist.*, p. 251, A; *Parmenid.*, p. 129, E, &c.) From all this it will appear that Plato, like a writer of our own time, regarded philosophy as an undressing of the world, as the means of discovering the certainty and eternity, which are in this world hidden and wrapped up in the garb of the mutable and the temporal. For if the sensible is true, which he maintains against the Eleatics, it is true only through the essence of which it partakes (*Phæd.*, p. 100, C; *Euthydem.*, p. 300, E; *Sympos.*, p. 210, E), and therefore the object of philosophy must be to strip off this garment of the sensible, and ascend to the supreme idea which contains all the subordinate ones, and which has nothing in it capable of being apprehended by the senses, for individual ideas are but hypothetical notions, for which a true ground can only be given by a higher hypothesis. (*Respubl.*, vi., p. 511, B, compared with *Phæd.*, p. 100, A, *Philebus.*, p. 20, D, and *Respubl.*, p. 610, C.) This supreme idea is *God*; and thus God is the common standard of all things, and not the individual man, as Protagoras said. (*Legg.*, iv., p. 716, C.)

Before we pass from this outline of Plato's dialectical system to its application to ethics and physics, it will be advantageous to the reader that he should see how Plato made this application himself. With this view we shall give a sketch of the mode of reasoning which the philosopher has adopted in two most important and interesting dialogues, the 'Gorgias' and 'Theætetus,' which are the counterparts of one another, and which Schleiermacher places at the head of the second class of Plato's works, the dialogues of which occupy a middle position between the elementary and constructive ones, and treat not of the *method* of philosophy, as is the case with dialogues of the first class, but of its *object*. The opposition between these two dialogues has been well pointed out by Schleiermacher, in his introduction to the former of them (p. 5, seqq.). The highest and most general problem of science is to seize upon essence and being while still enveloped in the fleeting and transitory phantasmagoria of the senses, to represent the former as that which is real and good in the latter, and to point out and reconcile the apparent opposition between these two contrasted objects of contemplation. There are two ways of effecting this: the immediate method, or that by which we pass at once from the true to its semblance; the indirect method, or that by which we pass from the feeling of opposition, as a datum, to the primary intention, which forms the starting point in the other case. In the opposition which it is the object of these methods to reconcile, the antithesis is between *being* and *semblance:* in ethics this amounts to the antithesis of *moral good*, in the province of being, to *pleasure*, or *pleasurable feelings*, in the province of semblance; and in physics this is the antithesis of *science*, in the one domain, to *sensation*, in the other. The 'Gorgias' is the development of the former antithesis; the 'Theætetus' of the latter.

The interlocutors in the *Gorgias* are—Gorgias, the celebrated sophist and rhetorician; Polus, a rich and arrogant Agrigentine, who had written a book on rhetoric; and Callicles of Acharnæ, an ambitious demagogue; to whom are opposed Socrates and his friend Chærephon, the latter of whom however takes but little share in the discussion. The business of the dialogue is divided into three parts. I. The refutation of Gorgias with regard to the subject of rhetoric. Gorgias says the subjects of rhetoric are justice and injustice, but that the rhetorician sometimes acts unjustly; 'but,' says Socrates, 'if justice and injustice are the subjects of the rhetorician's art, the rhetorician, as such, must be just always: therefore Gorgias contradicts himself.' II. The refutation of Polus with regard to the distinction between the good or the beautiful, and the pleasant. Polus says, 'to act unjustly has less of the *beautiful* (it is αἴσχιον) than to suffer injury, but the latter has less of the *good* (it is κάκιον) than the former.' Socrates replies, 'the *beautiful* (τὸ καλὸν) excels in pleasure (ἡδονῇ), in utility (ὠφελείᾳ) or in both: the *deformed* (τὸ αἰσχρὸν) is so called from the pain (λύπη) or evil (κακὸν) which attends it, or from both: to act unjustly (τὸ ἀδικεῖν) does not surpass the suffering of an injury (τὸ ἀδικεῖσθαι) in the *pain* which attends it; consequently it must surpass it in the *evil* or *badness* of it, therefore it is both worse (κάκιον), and has also less of the beautiful (τὸ καλόν); and therefore it will not be a reasonable object of preference. Again, it is well for the unjust man to be punished; for the act and the suffering are homologous: now the act of punishing an unjust man is just; therefore the suffering of the unjust man is just also: consequently, as before, it is καλόν; therefore it has some excellence either of pleasure or of profit: but its excellence is not of pleasure; therefore it is profitable for him. III. The refutation of Callicles with regard to the proposition that all *good* is exhausted in the *pleasant*. Callicles asserts that though τὸ ἀδικεῖν has more of deformity than τὸ ἀδικεῖσθαι, this is only by law or convention, and not by nature. For τὸ ἀδικεῖν is an endeavour to get more than others, and this is natural. Socrates first confutes Callicles' idea of a distinction between law and nature (p. 488, B, 489), and then brings three decisive arguments against his position that everything pleasant is good, the first in p. 495, D, the second in p. 495, E—497, D, the third in p. 499, E—499, B. To escape from the consequences of these arguments, Callicles makes a distinction between good and bad pleasures; but Socrates refutes this at once by showing that if we are to make this distinction, it follows that we seek for an object not because it is pleasurable, but because it is good (p. 499, B, 500, A); and then maintains that the rhetoric, or what is the same thing, the political principles of demagogues, like Callicles, are morally bad, for they have *pleasure* for their object, not *good*. Socrates then proceeds by himself to show that happiness consists in justice and order (p. 506-508); that life is not in itself desirable (p. 508-512), and so on: and the dialogue concludes with a fable relating to the state of the soul after death.

The interlocutors in the *Theætetus* are Theodorus, a mathematician of Cyrene, who is represented as attached to the materialism of Protagoras, and a young Athenian named Theætetus, who carries on nearly the whole of the argument with Socrates. The dialogue consists of a refutation of three positions with regard to science (ἐπιστήμη), which are put into the mouth of Theætetus. (I.) That science is sensation (αἴσθησις). This, says Socrates, is much the same as the dogma of Protagoras, 'the individual man is the standard of all things' (πάντων μέτρον ἄνθρωπος); for his φαίνεται, 'it appears,' is equivalent to your αἰσθάνομαι, 'I perceive;' but in this opinion of Protagoras is implied (1) that there is only a *genesis* and no *being*, and that all things are the offspring of flowing and motion; (2) that the objects of the senses have neither an objective nor a subjective existence, but exist only by the concurrence of object and subject: that is to say, according to his principle, τὸ πᾶν κίνησίς ἐστι, 'every thing is motion.' Now, there are two kinds of motion, (1) active, (2) passive; the first comprehends the αἰσθήσεις (perceptions), the second the αἰσθητά (things perceived), and qualities are generated from the concurrence of the percipient and the perceivable. Hence, it follows, according to Protagoras, that nothing *is* of itself, but *comes into being* by the instrumentality of something else (οὐδὲν εἶναι ἓν αὐτὸ καθ' αὑτὸ, ἀλλά τινι ἀεὶ γίγνεσθαι, p. 157, A). Socrates next proceeds to show, in defence of Protagoras, that the objection in respect to dreams and madness is of no force, and that the perceptions of a person mad or asleep are true as far as they go; for, in the first place, we have no means of proving that we are not asleep when we think ourselves awake; and next, it may be shown that, whatever we perceive, we alone perceive it, and that therefore the perception, if it is a perception at all, must be a true one. The opinion of Theætetus, thus far established, is of no validity unless we admit that Protagoras has overthrown his pretensions to superior wisdom by advancing this doctrine. Socrates however concedes that Protagoras might reasonably object to this confutation as not amounting to a regular proof. In the next place then he shows that if perception is science, we arrive at the absurd conclusion that it is possible to remember a thing once known, and yet not to know it. He checks himself however by suggesting (p. 114, C) that this *reductio ad absurdum* has been obtained by an acquiescence in the common acceptations of terms (πρὸς τὰς τῶν ὀνομάτων ὁμολογίας ἀνομολογησάμενοι), and then undertakes to defend the doctrine of Protagoras as far as it will go. Speaking then in the person of Protagoras, he begins by denying that perception (αἴσθησις) and memory (μνήμη) are the same affection (πάθος). Next, he denies that he considers all men alike in wisdom. He says that some opinions may be better than others; but he denies that any are false; and having, in the name of Protagoras, found fault with himself for his mode of arguing, he invites Theodorus to answer him in Protagoras's name. Theodorus having reluctantly consented to do so, Socrates proceeds (p. 170, A) to refute seriously the πάντων μέτρον ἄνθρωπος of Protagoras. In the first place he asserts that almost every action of man implies the belief that there are different degrees of wisdom, and therefore that there is such a thing as false opinion. Next, he shows that Protagoras himself must confess his opinion to be false, if it be conceded that most people think it so, and that all these think rightly. Again, this rule of Protagoras will not apply to the profitable, and this Socrates, after a digression on the difference between the babbling politician and the true philosopher, proceeds (p. 177, C) to prove by showing that the profitable belongs to the *future*, and that no one excepting the man of science can judge of the future as respecting the object of his science. These two last conclusions Theodorus admits to be decisive (p. 179, B, C); but Socrates doubts if the refutation of Protagoras as regards the *present* be made out, unless the Heracleitean doctrine be also refuted. This then is the next step. In the first place he makes Theodorus concede that all things are moved according to both kinds of motion, *i.e.* change of place and change of form. Then alluding to his former distinction of *τὰ ποιοῦντα = τὰ αἰσθητά*, and *τὰ πάσχοντα = τὰ αἰσθανόμενα*, and to what he said about the effects of their concurrence, he shows that, according to this doctrine, no quality can be predicated of anything; and that we neither can be said to perceive, nor yet not to perceive, *i.e.* neither to have science nor to have it not; and hence every proposition is equally right and equally wrong, and nothing is left but the *οὐδ' ὅπως*. To this Socrates adds (p. 184, C) that the senses are the *δι 'οὖ*, not the *ᾧ αἰσθανόμεθα*—the mere instruments, not the causes of sensations; we perceive each sort or quality by a different *δι 'οὖ*, or organ, and consequently must compare them, &c., by some other means than by the senses themselves, *i.e.* the *ψυχὴ αὐτὴ καθ' αὑτήν*, 'the soul considered as unconnected with the senses,' is the subject of essence and truth, and therefore science and sensation are different, for science is not without essence and truth. 'Hence it follows,' says Socrates, 'that we must seek for science in that name, whatever it is, which is given to the soul when it is engaged in abstract speculation.' (p. 187, A.) From this, Theætetus asserts (II.) that science is right conception (*ἡ ἀληθὴς δόξα*), and when he is driven from this, after a series of subtle disquisitions on the nature of false conception, he maintains (III.) that science is right conception combined with reasonable explanation (*ἡ μετὰ λόγου ἀληθὴς δόξα, i.e. ὧν μή ἐστι λόγος, οὐκ ἐπιστητά ἐστι*, p. 201, D). This is discussed with reference to the different meanings of *λόγος*, and the opinion is finally refuted. The dialogue ends with this recapitulation of the results obtained:—'Therefore neither perception nor right conception, nor right conception, combined with reasonable explanation, can be *science*' (*οὔτε ἄρα αἴσθησις οὔτε δόξα ἀληθὴς οὔτε μετὰ ἀληθοῦς δόξης λόγος προσγιγνόμενος ἐπιστήμη ἂν εἴη*).

We have dwelt at some length upon these two dialogues because they furnish a direct transition to Plato's application of his dialectical system to the departments of ethics and physics. The *Gorgias* points out the steps by which Plato would proceed in handling the moral questions of common occurrence in his time; for ethics was always treated in those days as a part of politics, and the sophists, to whom he was opposed, were principally dangerous from the bearing of their doctrines on political morality. The *Theætetus* is a critical review of certain materialistic opinions, which it was necessary to confute before a new system could be fairly set on foot. Plato himself says, 'It is better to do a little well than a great deal in an unsatisfactory manner' (*Theætet.*, p. 187, E); and as Sir C. Wren gained nearly as much credit for the scientific manner in which he removed the ruins of the old St. Paul's church as for the genius and skill with which he planned and constructed the new edifice, so Plato should receive the commendation which is due to him for the elaborate and searching scrutiny to which he subjected the erroneous views current in his time, before he ventured to propound the grand and original conceptions on which his own philosophy was built up.

II. The ethical system of Plato, though traces of his views in this field are discernible in many of his other dialogues, is most fully developed in his two largest treatises, the 'Republic' and the 'Laws,' and most distinctly in the former. From Plato's general plan of considering everything controversially and with reference to the theories of his predecessors, we might draw two conclusions with regard to his system of moral philosophy: 1st, that he would at once discard the notion that the pleasure resulting from sensible impressions could be the highest good, for this would be to allow the influence of the senses to be paramount, the very point in which he was so directly opposed to the Heracleiteans; 2ndly, that he would also reject the claim of knowledge alone to be considered as the good, for that would lead him to coincide, more nearly than would have suited his general views, with the positions of the Eleatics. We see the first germs of his opinions on these two points in the contrast which we have pointed out between the 'Gorgias' and 'Theætetus;' and in the 'Philebus,' which may justly be considered as an introduction to the 'Republic,' he formally confutes the dogma that the *summum bonum* is either pleasure or knowledge alone. The highest good, as is hinted in the 'Philebus,' and distinctly shown in the 'Republic,' is moral virtue: this principle is the basis of man's intellectual and moral constitution; it is his good *quo* man, that is, as far as he is an intellectual and moral agent. Moral virtue, according to Plato, is the subordination of man's lower faculties to his reason as the sovereign faculty: a man is virtuous when the will acts as the servant of the reason in controlling the appetite. When this subordination is perfect in the individual, it constitutes his rectitude, righteousness, justice, or, in general, his virtue or goodness; consequently, his happiness in this world. When a corresponding subordination exists in the state, that is to say, when the guards, or military caste, in perfect subordination to philosophic rulers, assist the reasoning and governing power in regulating and controlling the passions of the populace, the state is a perfect one. The 'Republic' of Plato is a development of this analogy between the ideas of the perfect man and the perfect state. This analogy depends upon the old and well-known division of virtue into the four cardinal virtues, as they are called, namely (1), prudence or wisdom (*φρόνησις*); (2), courage, constancy, or fortitude (*ἀνδρεία*); (3), temperance, discretion, or self-control (*σωφροσύνη*), and (4), justice or righteousness (*δικαιοσύνη*): and on the supposition that the whole province of virtue is exhausted by these four virtues. We cannot agree with Schleiermacher (*Einleitung zum Staat*, p. 26), that 'Plato manifestly took up his description of the four connected virtues only out of respect for the existing classification, just as they had passed in a similar manner from common conventional usage into the philosophy of Socrates.' To us it appears that the classification of the four cardinal virtues is so intimately connected with the very groundwork of Plato's whole physical and dialectical system, that it must have been in the most serious earnest, and with the most deliberate choice, that he assumed this division of virtue as the basis of his moral philosophy. In the 'Republic,' Plato argues thus with regard to the fourfold division of virtue (*De Republ.*, iv., p. 427-434):—The state, being a perfect one, must exhibit in itself the four cardinal virtues; not that every one of its citizens must exhibit them all perfectly: but the philosophic rulers will represent its *φρόνησις*; the courageous standing-army its *ἀνδρεία*; and the well-conducted populace and craftsmen its *σωφροσύνη*. The remaining virtue, *δικαιοσύνη*, is the virtue of the whole; it is the principle and cause of the existence of the other three virtues, compelling each portion of the state to keep to its own business, and to abstain from all *πολυπραγμοσύνη*, or interference with the affairs of the other portions. Passing from the state to the individual, Plato recognises three distinct principles in the soul of man: *τὸ λογιστικόν, τὸ θυμοειδές*, and *τὸ ἐπιθυμητικόν* (p. 439, D): the first belongs to the rational part of the soul; the two last to the irrational part, with this distinction, that the *θυμοειδές*, though it is classed under the same general head with the *ἐπιθυμητικόν*, is very different from it, and often assists the *λογιστικὸν* in governing and controlling the *ἐπιθυμητικόν* (p. 440, A; p. 441, E). These three principles correspond in our philosophical language to the reason, the will, and the appetite. The second is often rendered 'the irascible principle,' and Cicero translated it by *ira* and *iracundia* (*De Republ.*, i. 38); but we follow Hooker, who translates it 'the will,' and Hemsterhuys the younger, who substitutes for it the scholastic synonym *velleité*. These three principles in the soul of man Plato considers to be analogous to the three classes in the perfect state: the philosophic rulers represent the reason, the standing army is the will, and the populace the appetite; and as there was a virtue corresponding to each of the divisions of the perfect state, and also one which ke[illegible] them all together, so, in the righteous or virtuous man, the reason is full of wisdom, the will is strong in fortitude, and the appetite is under the healthy influence of self-control; and all three are kept together by justice, as the musical harmony keeps together the highest, the lowest, and the middle sound, or the octave, the bass, and the fifth (p. 443, D); or, to express the whole in the words which Shakspere has apparently borrowed from Plato (*Hen. V.*, act i., sc 2):—

Exet. While that the armed hand doth fight abroad,
The advised head defends itself at home;
For government, through high, and low, and lower,
Put into parts, doth keep in one concent,
Congreeing in a full and natural close,
Like music.

Cant. Therefore doth heaven divide
The state of man in divers functions,
Setting endeavour in continual motion,
To which is fixed, as an aim or butt,
Obedience.

'This idea of the three principles in the human soul, and of the subordination of the two inferior faculties to the sovereign reason, is most beautifully and clearly worked out in the mythus which forms a prominent part of Plato's earliest dialogue, the 'Phædrus' (p. 246, A, seqq.), where the soul is compared to a charioteer (the reason) driving a pair of winged steeds, one of which is well-bred and well-trained, and the other quite the contrary: the quiet horse (the will) is obedient to the rein, and strives to draw its wilder yoke-fellow (the appetite) along with it, and to induce it to listen to the voice of the charioteer (the reason); but they have both of them much pain and trouble with it, and the whole object of their charioteering is lost if it contrives to get the better of them. In this allegory the aim of the reason in exacting obedience from the lower faculties is not merely this obedience or subordination itself, which constitutes the goodness of man; the reason endeavours, by keeping under control the senses, with all their cravings for gratification, to take a calm view of abstract truth, and to gaze upon the eternal realities which are here clothed in the garb of space and time. This is described as if the soul, in its state of previous existence, went the circuit of the universe in the train of the gods: if, in performing this journey, the reason, or charioteer, could control his restive steed so as to raise his own head above the surface of the heavenly vault, he was borne round with the revolution of the sphere, and, in that position, though struggling and striving with his unruly steed, he saw, however faintly and imperfectly, the essences of things which are collected in that super-celestial region, and the remembrances of which furnish the soul with ideas after it has descended to earth and become united with a body. Now this is carrying the definition of moral excellence, or virtue, one step farther. A man is in a state of virtue, righteousness, or moral excellence, when his will and his appetite are subordinated to his reason; but this subordination is necessary as a previous condition, in order that a man may contemplate the idea of the good; or, in our phraseology, a man must be in a moral state before he can place himself in a religious state. This idea of the good, the real *summum bonum*, the complement of all morality, is discussed in a remarkable passage of the 'Republic' (vi., p. 505, A, seqq.), in which Plato takes up and finishes the argument in the 'Philebus.' It was there shown that the *summum bonum* is not to be sought either in pleasure or in knowledge: it remained to be shown then in what this *summum bonum* actually consists; in other words, what is its *idea*. In the language of Plato, *idea* and *essence* are synonymous. Thus by the idea of the good, he only means the nature and essence of good, or of the sovereign good, that is, of God, and not in this case the abstract and intellectual image which we form of it. In opposition to this idea or essence, Plato uses the term *generation*, or *becoming*, by which he means all sensible things, everything that is born and perishes. Corresponding to this opposition of *generation* to *essence*, Plato, following Parmenides (Simplicius, on Aristotle's *Phys.*, fol. 7, B.), supposed two worlds, the world of matter and the world of mind, the visible and the ideal world; the former being on the model of the latter. Immutable essences, or ideas, are contained in the ideal world. Material essences, or substances, are not real essences, for they are subject to generation and corruption; we cannot predicate *εἶναι* of them; they can only be said *γίγνεσθαι*. Having premised, or rather reminded his readers of this opposition of the *ὁρατὸς τόπος* to the *νοητὸς τόπος* (p. 507, B.), Plato proceeds in the following strain:—The sun is an image of the idea of the good; for while the other senses, such as the hearing, need nothing intermediate or additional in order to the perception of objects, sight, on the other hand, does need the intervention of light, otherwise the colour and the form will not be visible: this light is derived from the sun, and the benefit which our sight derives from the sun is analogous to the benefit which our reason derives from the idea of the good; for as the eye cannot see without the intervention of light, so the reason cannot discern the things of the ideal world without the light of truth. Consequently, the idea of the good is that which imparts truth to the objects of our reason and the power of discerning truth to the reason itself. The idea of the good is therefore far above truth and the knowledge of truth; and as light and the power of seeing are akin to the sun, but not identical with it, so truth and the knowledge of truth are related to the idea of the good, but are not identical with this idea. The sun is also an image of the idea of the good in this, that as the sun not merely enables the eye to see, but likewise supplies nourishment and growth to the visible objects; so the idea of the good not merely enables the reason to discern and know, but likewise gives to the ideas of the reason their being and reality. Accordingly, as the sun, to borrow a phrase from Milton, looks from his sole dominion like the god of this lower world of sense, so the idea of the good, the sovereign good, even God himself, reigns supreme in the higher world of ideas which is cognisable only to the reason. Plato concludes this discussion with a classification which may be considered as a supplement to the negative argument of the *Theætetus*, in the same way as the first part of this disquisition completes the negative argument of the *Philebus*. As there are two provinces or worlds, the ideal and the visible—the world of reason and the world of sense, so there are in each two sorts of essences or substances, namely the pure and the mixed. First, then, the essences or objects of the pure reason are of two sorts: 1, pure, as the ideas of good, beauty, justice, &c.; 2, mixed, or into the conception of which an image necessarily enters: as the idea or essence of a triangle or circle, &c. Secondly, the material substances or objects of sense are also of two sorts: 1, bodies; 2, images, or shadows of bodies. To these four species of objects, four species of knowledge correspond, the two first of which, or those pertaining to the objects of the ideal world, are alone worthy to be called by the name of that *ἐπιστήμη*, or science, which Theætetus sought for in vain.

I. Science (*ἐπιστήμη*).

1, *νόησις*, the knowledge of pure ideas.

2, *διάνοια*, that of mixed ideas.

II. Opinion (*δόξα*).

3, *πίστις*, knowledge of bodies and of what pertains thereto.

4, *εἰκασία*, knowledge of the images or shadows of bodies.

To return however to Plato's ethical system: in this the end is the same as that of his dialectics; from first to last there is a resolute struggle with the domineering pretensions of the senses and a striving after a something higher and holier than this world can furnish. Everything is ascribed to reason and faith: to reason, as the highest faculty of man, to which every other faculty should be subject; to faith, as the evidence of those unseen objects which the reason worshipped and set up in opposition to the *idola* of the senses. From this general explanation it will be seen what is the tendency of such questions as 'whether virtue is capable of being taught?' (Plato's *Meno.*, with the criticism in Aristot., *Ethic. Nicom.*, vi. 13); and it may also be inferred from this that Aristotle has completely misunderstood and misrepresented his master in his criticism of Plato's 'idea of the good.' (*Ethic. Nicom.*, i. 6; *Metaphys.*, xii. 1, seqq.)

It will not be expected that we should here enter upon a minute examination of the political theories which Plato has based upon his ethical system. It will be sufficient to say briefly that Plato's views decidedly tended towards oligarchy, or, as he would have called it, aristocracy. He had a great admiration for Dorian institutions, and a great aversion to democracies, especially to that of Athens. His connection with the chief agents in the oligarchal revolution at Athens may have had some share in this, and it is certainly some proof of the intimate connection between his political opinions and those of the party to which we refer, that the interlocutors in the great trilogy of dialogues, which contains the 'Republic,' the 'Timæus,' and the 'Critias,' are (besides Socrates, whose political character is not altogether without suspicion) the Syracusan Hermocrates, the deadliest foe of Athens, Critias, the head of the thirty tyrants, and Timæus the speculative Locrian legislator. From a set of dialogues managed by such persons as these we should hardly expect anything different in politics from what we find in them; an attempt, namely, to recommend, by argument and fiction, a system of government based upon Dorian and immediately upon Lacedæmonian institutions. There is something eminently unfeeling in the manner in which Plato, after the example of the Lacedæmonians, considers marriage in a gross and physical light, and subordinates all the better sentiments of human nature to the harsh jurisdiction of an uncompromising aristocracy. It has been supposed (by Morgenstern, *Commentat. de Republ. Platonis*, p. 73, seqq.) that one of the later comedies of Aristophanes, the 'Ecclesiazusæ,' is directed against this λακωνομανία of the great philosopher. Stallbaum (*Prolegom. ad Platon. Rempubl.*, p. 68, seqq.) has opposed this conjecture with some chronological arguments, which Meineke (*Histor. Crit. Com. Græc.*, p. 289) does not consider satisfactory. Meineke thinks that Plato's scheme for a community of property and wives is undoubtedly ridiculed in the 'Ecclesiazusæ,' and adduces as an additional argument for this the satirical remarks of Aristophanes upon one Aristyllus (*Eccles.*, 646; Plut., 313), whose name Meineke, following some old grammarians (Eustath., p. 989; *Etym. M.*, p. 142, F), regards as a diminutive form of Aristocles, Plato's original name. We know that in general the Greek comedians were not unwilling to seize upon an opportunity of ridiculing the leader of any philosophical school, and Plato certainly did not escape literary satire of this kind. (Meineke, *Histor. Crit. Com. Græc.*, pp. 238, 240.) Of the *Laws* as related to the *Republic* we have already said as much as seems to be necessary.

III. Plato's physical speculations have less interest for the modern reader than either his dialectics or their application to moral philosophy. In this, as in the other departments, Plato starts with a critical review of the systems which preceded him. The earliest philosophical systems among the Greeks, those namely which we assign to the Ionian school, were solely physical; and they started always from some theory with regard to the origin of things. According to Thales, this primitive element was *water;* according to Anaximenes, it was *air;* according to Heracleitus, it was *fire;* Anaximander considered the world, in its primitive state, as a vast and infinite chaos; Diogenes regarded it as originating in a rational and intelligent principle; and Anaxagoras, uniting in one the views of the two last-named philosophers, recognised a supreme mind (νοῦς) as the principle of life, which imparted motion and form to the material elements, and reduced to order the chaotic mass of primitive atoms. The Eleatic school of philosophy began with the position which thus formed the culminating point of the Ionian school—the admission of a supreme intelligence. According to the Ionians, and in the very language of Thales and Heracleitus, 'All the universe was full of gods.' (Aristot., *De Anima*, i. 5; *De Part. Animal.*, i. 5.) According to the pantheism of the Eleatics, on the contrary, the universe itself was the Deity; in the words of Xenophanes, the one being (τὸ ἓν), the *universe*, was God. (Aristot., *Metaphys.*, i. 5, sec. 12.) 'As Thales saw gods in all things, so it may be said that Xenophanes saw all things in God.' (Thirlwall, *Hist. Gr.*, ii., p. 136.) Parmenides endeavoured to demonstrate this pantheistic view of Xenophanes by arguments deduced from the idea of existence, which denied the possibility of creation and total destruction. In this view he was followed by Empedocles, who also held the doctrine of uncreated and indestructible existence. At an earlier period, Pythagoras had maintained that *numbers* are the principles and essence of all things, and that the world subsists by a numerical harmony, a view which his contemporary and rival, Heracleitus, adopted under a modified form (Plato, *Sympos.*, p. 187, A); and Empedocles, who seems to have combined many views peculiar to the Eleatics with some of the doctrines of Anaxagoras, also, as has been mentioned above, forms the link of connection between the Eleatics and the Pythagoreans. As this was the general state of physical science when Plato wrote, and as he seems to have been always striving to reconcile the contradictory systems of Heracleitus and the Eleatics, and to extract from them their common element of truth, we may see both how Plato would proceed in constructing a theory of the universe, and how this theory would be connected with his dialectical system and his theory of ideas. It is obvious that he would maintain a creation, in opposition to Parmenides and Empedocles, and would oppose himself in this, as in his dialectics, to the perpetual flux of Heracleitus: and this we shall find to have been his method, if we compare the 'Philebus' and the 'Parmenides' with the 'Timæus,' which contains the fullest development of Plato's physical and cosmogonical system. We also observe in the 'Timæus,' and in a celebrated passage of the 'Republic' (viii., *ad init.*), that Plato attached a great weight to the numerical theory of Pythagoras, though we do not know enough of the latter to be able to determine the exact amount of Plato's obligation to him in the musical harmony on which he makes his universe depend, and the complicated numerical relations by which he estimates the durability of his state. In the 'Timæus,' as in everything else, he starts with the opposition of immutable essences to mutable substances, and begins by stating the contrast between the unity of the idea, as real existence, and the multiplicity of things, as only a seeming existence. The latter, according to Plato's system, are treated after the semblance of the former, which is their ἰδέα, or παράδειγμα. In this way of viewing the subject, Plato's physical theory at once assumes the form of a history of the creation, a κοσμοποιΐα, and is therefore in itself, to a certain extent, necessarily mythical. The first great principle (the τὸ ἓν of the later Ionians, which is the τὸ ὂν of the Eleatics) is described as engaged in reducing to order the chaos of material substances. That this must have been done at some time,—that there must have been a beginning to the world (ὁ οὐρανός, ὁ κόσμος, τὸ πᾶν), that the world which we see must have been *created*, for this position Plato argues most distinctly, in opposition to the Eleatics. As the world which we see is within the domain of the senses, it is, for this very reason, one of those things which are liable to generation and decay. It must therefore have had its maker, or δημιουργός. Now this maker can be no other than the formative principle—the *one*, the *existent*. From the beauty, order, and constancy discernible even in this lower world, it is clear, Plato says, that the creator must have constructed it after the model or pattern of a perfect and eternal world (*Timæus*, p. 29, A); and in order that this might be done in the most perfect manner possible, he made it a ζῷον ἔμψυχον ἔννουν τε, 'a living animal, gifted with intelligence' (*Tim.*, p. 30, B), by enduing it with a living soul. The body of this animal was composed of the four elements (and here Plato modifies and combines the theories of Empedocles and Anaxagoras), and the soul of the world was not, as the Eleatic pantheism would have maintained, God himself, but an emanation and product of that intelligence which is the cause of all things. For Plato, both in the 'Timæus' and in the 'Philebus,' speaks distinctly of the *mind* as of the nature of the cause. In the 'Philebus' (p. 27 B, seqq.), after enumerating four kinds of being—the infinite, the limit, the mixture of these two, and the cause—and alluding to the universally received dogma that the mind (νοῦς) is the sovereign of heaven and earth (p. 28, C), he proceeds as follows (p. 29, A):—'We find that fire, water, air, and earth must naturally be in the composition of all bodies. Those elements which we find in individual bodies receive their being from the elements which we find in the universe, and this little body of ours owes its nourishment and all that it has received or possesses to the great body of the world. Now these bodies of ours are animated by souls; and from whence should they derive their souls, if the great body of the universe, which has all the same elements with them, only in far greater purity and perfection, did not possess a soul as our bodies do? Since then we admit in all bodies four sorts of being—the infinite, the limit, the compound of these, and the cause; and since we find in the part of the universe to which we belong that there are causes which create souls, produce health of the body, and effect cures for diseases of the body; and causes which put together other compositions and amend them when impaired,—all of these causes having names which betoken some kind of wisdom or skill;—this being the case, we cannot but think that the whole heaven, possessing the same four sorts of beings, but possessing them pure and undepraved, has for its cause the nature of those things which are most beautiful and noble, a cause which may most justly be called wisdom and mind; and as wisdom and mind cannot be without soul, it follows that the world has a soul and mind from the power of the cause, and that mind is of the nature of the cause of all things.' It should be remarked that Plato distinguished, both in the 'Timæus' and in the 'Philebus,' between the αἰτία, or δι' ὅ (the inducement or moving cause for the creation), and the αἴτιον or ὑφ' οὗ (the efficient cause of the creation). 'The *nature* of that which effects (τὸ ποιοῦν) differs only in name from the moving cause (ἡ αἰτία), and we should be right in identifying that which effects with the efficient cause (τὸ αἴτιον).' (*Phileb.*, p. 26, E.) Now the αἰτία of the creation is the goodness of the creator (*Tim.*, p. 29, E), and its αἴτιον was the universal intelligence. Or as Philo Judæus says (i., p. 162), 'Behold this world! you will find that its efficient cause is God, by whom it was brought into being; its moving cause, the goodness of the creator.' The mind, which thus operates as a cause in setting *bounds* to the *infinite*, and so combining the infinite with the limit, was not the deity himself, but was taken by the deity and placed in the world as its soul. It was a function of the soul which the deity infused into the world, and was akin to the soul existing in each individual man. The great difference between the individual man, ζῷον κατὰ μέρος, and the world out of which he was formed, consisted in the need of organs by the former, whose soul is thus necessarily connected with the faculty of perception (αἴσθησις). So far as the soul of man is connected with perception, it is mortal; it dies with the body of the percipient. But, as the individual body after death unites itself with the great body of the universe from which it sprung, so also the soul, so far as it is not represented by the bodily perceptions, returns to the great soul of the world, of which it is an emanation, and remains undestroyed and indestructible. In this part of the subject, the views on the immortality of the soul, developed in the 'Phædo' (p. 78-80), come to the aid of the physiological investigations in the 'Timæus.' It was a necessary consequence of this way of considering the origin of things, that Plato should maintain the reality of time in opposition to Parmenides. (*Timæus*, p. 37, C, 39, E.) As the multiplicity of things (the πολλά) presumes the universal (the ἕν), and as the bound points to the infinite, so, conversely, there must be time as the image and product—the limitation or bound—of eternity. Thus much may suffice for a general view of Plato's physical theory, for it would not be possible within our narrow limits to enter upon a discussion of his speculations in astronomy and natural history, and of his notions with regard to the origin of evil in general (*Epist.*, ii., p. 313, A), and of diseases in particular (*Tim.*, p. 81-86); and from this the reader will easily see that the method which Plato followed in this department was uniformly consistent with that which he adopted in other fields of inquiry. His object in this, as in everything else, was to discern the one in the many, and, while he demonstrated the existence of the former against the Heracleiteans, to assert the reality of the latter against the Eleatics. This, we have seen, was from first to last Plato's great general object: this idea was the foundation of his dialectic system; it was the guiding-post which directed him to the right end in his moral and physical speculations; it was the clue by which he sought, and seldom sought in vain, for the truths which had eluded the search of all his predecessors.

From this general review of Plato's philosophy, necessarily an imperfect one, the reader has, we hope, formed some estimate of the Catholic spirit of this great writer, and the grand and original conceptions by which he endeavoured to unite in one great system all that was true in the results of previous investigations. Plato was the greatest of all philosophers, because he was the first who adopted a true method, and followed it out in all its bearings and applications. It would not be easy to overrate the influence which Plato's works have exercised upon the speculations of all subsequent inquiries. Although his name has not been so much bandied about for good or for ill as that of his scholar Aristotle, his intellectual empire has been neither less extensive nor less durable. Coleridge has said that all men are born disciples of either Aristotle or Plato (*Table-Talk*, p. 95); a saying which, as far as it goes, is perfectly true. It means that the doctrines which Plato was the first to proclaim to the world, will always be adopted by those who come to the hearing of them, if their minds are akin to his; otherwise, they will have recourse to the modification of those doctrines which was propounded by Aristotle, whose mind was no less repugnant than their own to the spirit of Platonism. There is one field in which the immediate influence of Plato's philosophy has always been most especially active, namely, in Christian theology. Many of the opinions which are stigmatised as heretical may be traced to the Platonism of the early Fathers of the Church, and this is particularly the case with regard to the doctrine of the Trinity. That Plato himself entertained none of the opinions which have been attributed to him on this subject, has been most satisfactorily proved in an able 'Investigation of the Trinity of Plato and of Philo Judæus, and of the effects which an attachment to their writings had upon the the principles and reasonings of the Fathers of the Christian Church,' by Dr. Cæsar Morgan (Lond., 1795).

The Greek text of Plato's works was first established on a careful examination of all the MSS. by Immanuel Bekker (Berlin, 1816-1823). His edition was followed by the very elaborate one of Frederic Ast, the first volume of which appeared in 1819, and which is still in the course of publication. Godfrey Stallbaum, who published a critical edition in 1821-1826, is also engaged upon an elaborate, critical, and explanatory edition of all Plato's works, of which eight volumes have appeared. A complete French translation of Plato has been published by Victor Cousin. Schleiermacher's German translation is unfortunately incomplete, and we have no good English version of Plato's whole works; that by Tayler is far from satisfying the critical reader. Floyer Sydenham's translations are admirable, as far as they go, but this unfortunate scholar was unable to complete more than a very small portion of his design of presenting Plato in an English form. The books which have been written on Plato's philosophical system are very numerous. There is a voluminous work by Tennemann expressly on this subject: it is written too much with a reference to the Kantian philosophy, and, though very learned, appears to us rather heavy and unsatisfactory. Nor can we much recommend Van Heusde's *Initia Philosophiæ Platonicæ*, Traject., 1827, 1831. A good deal may be learned from Ast's *Platons Leben und Schriften*, Leipz., 1816, though the author has advanced some inadmissible paradoxes with regard to the genuineness of a number of works unquestionably written by Plato. There is also much valuable matter in the four books of *Prolegomena* to Stallbaum's edition of the *Parmenides* (Lips., 1839, pp. 4-343). But Plato is, above all others, a writer who must be studied in his own works; no exposition can give an adequate idea of the beauty of his style, or the clearness and cogency of his arguments, and he would escape many of the misrepresentations by which his literary character has been assailed, if his readers were more numerous, and if there were fewer persons to pronounce sentence upon him without having read a syllable of his writings.

PLATON, the celebrated archbishop of Moscow, whose family name was Levshin, was born June 24th, 1737. He was the son of a village priest near Moscow, in the university of which capital he received his education, and, besides studying the classical tongues, made considerable proficiency in the sciences. His talents soon caused him to be noticed, for while yet a student in theology, he was appointed, in 1757, teacher of poetry at the Moscow academy, and in the following year teacher of rhetoric at the seminary of the St. Sergius Lavra, or convent. He shortly afterwards entered the church, became successively hiero-monach, prefect of the seminary, and, in 1762, rector and professor of theology. That same year was marked by an event in his life that greatly contributed to his advancement, for on Catherine II.'s visit to the St. Sergius Lavra, after her coronation, he addressed the empress in a most eloquent discourse, and on another occasion preached before her. So favourable was the impression he made, that he was forthwith appointed court preacher and preceptor in matters of religion to the grand-duke (afterwards the emperor Paul), for whose instruction he drew up his 'Orthodox Faith, or Outlines of Christian Theology,' which is esteemed one of his best and most useful productions. During his residence at Petersburg he very frequently preached before the court, and also delivered on various occasions many of the discourses and orations which are among his printed works. His residence at Petersburg however did not exceed four years, for after being created member of the synod at Moscow, by an imperial order, he was made archbishop of Tver in 1770. His attention to the duties of his new office was assiduous and exemplary; for he not only set about improving the course of study pursued in the various seminaries throughout his diocese, but established a number of minor schools for religious instruction, and drew up two separate treatises, one for the use of the teachers, and the other for their pupils. He was also entrusted with the charge of instructing the princess of Würtemberg-Stuttgard, Maria Pheodorovna, the grand-duke's consort, in the tenets and doctrines of the Greco-Russian church. At the beginning of 1775 he received the empress at Tver, and proceeded with her and the grand-duke to Moscow, where he was advanced to that see, with permission to retain the archimandriteship of the Sergius Lavra. With the exception of some intervals occasioned by his being summoned to Petersburg, where he preached before the court, it was in that convent that he chiefly resided, until he erected another in its vicinity at his own expense, in 1785, called the Bethania. Two years afterwards he was made metropolitan of the Russian church, in which capacity he crowned the emperor Alexander, at Moscow, in 1801, delivering on that occasion a discourse that was translated into several modern languages, besides Latin and Greek. He died in his convent of Bethania, November 11-23, 1812.

His works, printed at different times, amount in all to twenty volumes, containing, besides various other pieces, 595 sermons, discourses, and orations. Many of these are considered masterpieces of style and of eloquence; but, as might be expected among so great a number, all are not equally finished as to manner, or original and impressive as to their subjects. A selection from them, consisting of the finest passages and thoughts was published in two volumes, in 1805.

Dr. Clarke has narrated some particulars of a conversation which he had with the archbishop, which exhibit him somewhat *en deshabille*. Mr. Heber (afterwards bishop of Calcutta), says of him—'This prelate has long been very famous in Russia as a man of ability. His piety has been questioned, but from his conversation we draw a very favourable idea of him. Some of his expressions would have rather singed the whiskers of a very orthodox man, but the frankness and openness of his manners, and the liberality of his sentiments, pleased us highly. His frankness on subjects of politics was remarkable.'

PLATTE, River. [Mississippi, River.]

PLATU'RA. [Viperidæ.]

PLATYCA'RCINUS, Latreille's name for a genus of *Cancerians;* it is the *Cancer* of Leach.

M. Milne Edwards is of opinion that this genus, as well as *Pseudocarcinus* and *Etisus*, approximates very closely to the Crabs (*Cancer*, Linn. and Milne Edwards) and to *Xantho;* indeed they were for a long time united under the same generic appellation. In fact, continues Mr. Edwards, the general form of the *Platycarcini* differs but little from that of *Xantho*.

Generic Character.—Carapace rather convex and very much widened; *front* narrow, nearly horizontal, and divided into many teeth, one of which occupies the median line. The latero-anterior borders of the carapace are divided by fissures into a great number of dentiform lobes; their posterior extremity reaches to the level of the anterior border of the cardiac region, and is continued with an elevated line which surmounts the latero-posterior border. The *internal antennæ*, instead of being bent back obliquely outwards, are turned nearly directly forwards. The *external antennæ* are disposed nearly as in *Etisus*, their basilary joint is very much developed, and is partially lodged in the space between the internal angle of the orbitary border and the front; but the second joint of these appendages, instead of springing near the external border of the first in the internal orbitary canthus, is inserted at a small distance from the antennary fosset, completely out of the orbit; for the rest, it is small, cylindrical, and presents nothing remarkable. The disposition of the pieces of the mouth, of the feet, and of the abdomen is nearly the same as in *Xantho*.

M. Milne Edwards divides the genus into two sections.

A.

Species having the external orbitary angle much more advanced than the neighbouring portion of the latero-anterior border of the carapace.

Example.—*Platycarcinus Pagurus* (*Cancer Mœnas*, Rond.; *Cancer Pagurus*, Linn. and Herbst; *Cancer fimbriatus*, Olivi.).

This is the well known *Black-clawed* or *Edible Crab*, a native of our coasts, and so highly prized for the table. It is the *Tourteau, Poupart, Houvet*, &c. of the French, and *Partan* of the Scotch. [Crab.]

B.

Species having the external orbitary angle more advanced than the neighbouring portion of the latero-anterior border of the *carapace*.

Example, *Platycarcinus irroratus*.

Locality.—The coasts of North America.

M. Milne Edwards divides the *Cancériens* into three great groups:—

1. *Cancériens Cryptopodes*, consisting of the genus *Œthra*. [Œthra.]
2. *Cancériens Arqués*, comprising the genera *Cancer, Carpilius, Zozymus, Lagostoma, Xantho, Chlorodius, Panopeus, Ozius, Pseudocarcinus, Etisus, Platycarcinus* (here treated of), *Pilumnus, Rupellia*, and *Pirimela*.
3. *Cancériens Quadrilatères*, embracing the genera *Eriphia, Trapezia*, and *Melia*.

Such of these forms as our limits permit us to notice are illustrated in this work.

Fossil Cancerians.

For M. Milne Edwards's notice of fossil crabs, see the article Crab, vol. viii., p. 126.

Zozymus also occurs in a fossil state.

PLATYCERCUS. [Psittacidæ.]

PLATYCRINI'TES. [Encrinites, vol. ix., p. 392.]

PLATYDA'CTYLUS. [Gecko, vol. xi., pp. 105, 106.] Mr. Swainson, in his 'Classification of Reptiles,' places the genus under the family *Iguanidæ*, with the following subgenera:—typical, *Platydactylus, Hemidactylus;* aberrant, *Ptilodactylus, Sphærodactylus*, and *Phyllodactylus*. (*Natural History of Fishes, Amphibians*, and *Reptiles*, 1839.)

PLATY'LEPAS, Dr. Leach's name for a genus of *Sessile Cirrhipeds*, whose shell is conical, depressed, consisting of six valves, each divided internally by an angular plate or buttress springing from the centre, and its operculum consisting of four valves in pairs. It differs from *Balanus, Coronula*, and other genera, in the internal structure of the valves. (*Chthalamus* of Blainv.)

PLATY'LOPHUS, Mr. Swainson's name for a genus of conirostral birds arranged by him as a subgenus of *Barita* [Barita], in the subfamily *Corvinæ*, or *Typical Crows*, family *Corvidæ*.

Generic Character.—Bill intermediate in form between *Vanga* and *Garrulus*. Culmen slightly curved; gonys ascending, curved. Front of the head and nostrils defended by stiff setaceous feathers. Nostrils oval, basal. Rictus bearded. Wings rounded; the primaries not much longer than the scapulars. Tail rounded, terminating in setaceous points. Feet moderate. Hinder toe and claw very strong; longer than the middle, which is short; lateral toes equal. Claws acute.

Example, *Platylophus galericulatus* (*Garrulus galericulatus of* Vieill.).

PLATY'MERA, a name given by M. Milne Edwards to a very remarkable genus of *Brachyurous crustaceans*, which is placed by him in the tribe of *Calappians* [Oxystomes], connecting on one side the *Calappæ* [Calappa] and *Mursia*, whilst it is also approximated by other characters to the *Cancerians*. [Crab; Platycarcinus.]

Generic Character.—Carapace very broad, tolerably elliptical, except that on each side it is prolonged into a strong spiniform tooth; its latero-anterior borders are not prolonged above the feet, as in *Calappa*. The *front* is triangular, and disposed as in *Calappa*, &c. The *orbits* are oval, deep, of moderate size; and a fissure may be remarked at the middle of their lower border. The internal and external *antennæ* are disposed nearly as in *Mursia*. The *buccal frame* is much wider anteriorly than in the other genera of the tribe, and the small portion of prelabial space which reaches beyond the external jaw-feet is not divided by a median partition, and is only imperfectly covered by the lamellar prolongations of the internal jaw-feet. The *external jaw-feet* are very wide anteriorly; their third joint, which is as long as the second, terminates by a rather large anterior border, and presents below its anterior and internal angle a great and deep notch, in which is inserted the fourth joint: this last is exposed, and very large, but does not reach the level of the anterior extremity of the third joint. The basilary appendage of these organs, which serves as a valve for closing the afferent apertures of the branchial cavities, is lamellar, very large, and semilunar. The *sternal plastron* is oval. The first pair of feet have nearly the same form and disposition as in the *Calappæ*, but the hands (manus) are longer and less elevated. The succeeding feet are very long and very much compressed; their third joint, or *femur*, is remarkably large and nearly lamellar, and the tarsi are long and styliform. The second pair are rather longer than the second and fourth: the fifth are much shorter than any of the others. The *abdomen* of the male is composed of five distinct joints, the third of which presents behind a very considerable transversal crest.

M. Milne Edwards, who gives the above description, states that he knows nothing of the manners of this genus, and describes one species only—*Platymera Gaudichaudii*, which is of a reddish colour, and three inches (French) in length.

Locality.—The coasts of Chile.

PLATYPUS. [Ornithorhynchus.] N.B. *Platypus* is also Herbst's name for a genus of coleopterous insects (*Bostrichus*, Fab.).

PLATYRHYNCHUS, Desmarest's name for a genus of *Muscicapidæ*. [Muscicapidæ.]

Mr. Swainson remarks that in *Todus* [Muscicapidæ] the bill exhibits a long and boat-shaped appearance, toge ther with a remarkably short tail, and delicate although lengthened legs. These latter characters are, he adds, continued to *Platyrhynchus*, but the bill in the latter has become so short and so broad as to present a miniature resemblance to that of *Eurylaimus* [Muscicapidæ]: the legs are long, but so remarkably slender as to show they are not at all adapted for walking.

Example, *Platyrhynchus cancromus*.

Locality.—Brazil. (*Zool. Ill.*, 1st series, pl. 116.)

Platyrhynchus is also M. F. Cuvier's name for a genus of *Seals*.

PLATY'STERA, a name given by Sir W. Jardine and Mr. Selby to a genus of flycatching birds, arranged by Mr. Swainson as a subgenus of *Todus*. [Muscicapidæ.]

PLATY'STOMA and **PLATY'STOMUS**, Mr. Swainson's name for a genus of the subfamily *Eurylaïminæ*. [Muscicapidæ.]

PLATYU'RUS, Mr. Swainson's name for a genus of Wrens. [Wrens.] But note: *Platyura* is Meigen's name for a genus of dipterous insects.

PLAUEN, one of the most considerable manufacturing towns in the kingdom of Saxony, is situated in a beautiful valley on the banks of the White Elster, 75 miles west-south-west of Dresden. It is in part well built, but suffered severely by a waterspout in 1834. Among the public buildings there are two churches, a royal palace, a lyceum with a seminary for schoolmasters, which is one of the handsomest buildings of the kind in the kingdom of Saxony, two hospitals, and two considerable orphan asylums. The principal church, the interior of which is distinguished by a noble simplicity, has a celebrated altar-piece by Matthæi, representing the Last Supper. The cotton manufactories are of great importance, but said not to be so flourishing as they once were. There are manufactories of stockings, net-lace, bobbin-net, oil-cloth, and extensive brandy distilleries. Plauen is the centre of the manufacture of muslins known by the name of Plauenscher Waare, which gives employment, in the circles of Voigtland (of which Plauen is the capital) and of the Erzgebirge, to 30,000 persons.

Plauen was in the thirteenth century a community of the Teutonic order. The population of Plauen is now nearly 9000.

(Stein; Cannabich; Engelhardt.)

PLAUTUS, MARCUS ACCIUS, was the greatest comic dramatist of Rome. His parents and the time of his birth are unknown, and scarcely anything that has come down to us respecting his personal history is worthy of credit. During the republic the Romans scarcely paid any attention to the personal history of their early poets, and when they began to collect materials for the purpose of writing their lives, they seem to have delighted in making up marvellous tales. It is however generally supposed that Plautus was born at Sarsina, a town in Umbria; and in common with other humourous writers of antiquity, he is described not only as a man of low birth, but of such bodily deformities that nature would seem to have purposely designed to make his countrymen laugh at his person as well as his wit.

It appears that Plautus commenced writing comedies very early, for A. Gellius (iii. 3.14) relates, on the authority of Varro, that after having made some money by his works which he seems to have sold to the ædiles, who had the superintendence of dramatic representations (Prolog. of *Amphitruo*, v. 72), and having embarked it in commercial speculations, he lost it all, and was reduced to poverty. Upon his return to Rome, he entered into the service of a baker, who employed him in grinding his corn by a hand-mill. While he was thus occupied he wrote three comedies, the 'Saturio,' the 'Addictus,' and a third, the name of which was not known to Gellius. Of the first two, only a few fragments are preserved. St. Jerome (in Euseb. *Chron.*, Ol. 145) describes his working in a bakehouse not as the consequence of a failure in commercial undertakings, but of a great scarcity then prevailing at Rome. But these statements, if there be any truth in them, may easily be reconciled by supposing that after he had lost his property, on his return to Rome his distress was increased by scarcity and dearth of provisions. From these isolated accounts we must infer that it was believed among the antients that after he had gained enough to enable him to leave his employer, he continued to live at Rome, devoting his time to his favourite pursuits. Whether he enjoyed the rights of a Roman citizen is not known. The time of his death is differently stated by Cicero and St. Jerome. The latter places his death in Olymp. 145, leaving it uncertain whether it took place in the first or the last year of that Olympiad. Cicero (*Brutus*, c. 15) says that Plautus died during the consulship of P. Claudius and L. Porcius, that is, 184 B.C., or Olymp. 148, 2. So much is certain, that the best period of the life of Plautus was the time immediately before and during the second Punic war.

The plays which then amused his countrymen retained their popularity for several centuries, for we see, from a passage of Arnobius, that the 'Amphitruo' was performed in the reign of Diocletian. It is impossible to ascertain the number of comedies which Plautus wrote, for in the time of Gellius no less than about 130 pieces bore the name of Plautus; most of them however were acknowledged not to be by him, but either, as Varro supposed, the work of one Plautius, or, as seemed more probable to Gellius, plays of earlier Roman dramatists which had been revised and improved by Plautus, and, on account of their similarity in style to his own works, were attributed to him. Many critics and grammarians, according to Gellius, were engaged in endeavouring to ascertain what comedies really belonged to Plautus. Varro, who wrote a work upon the subject entitled 'Quæstiones Plautinæ,' reduced their number to 21, which were designated *Varronianæ*, and which were generally acknowledged to be the real works of Plautus. L. Ælius added four others. Servius (*ad Æneid. I. init*) says that some ascribed to Plautus 20 comedies, others 40, and others 100. Amidst these various statements, it would be hopeless for us to attempt to discover the real number of his comedies, especially as we have no means of comparison, for the twenty comedies still extant were undoubtedly contained among the twenty-one *Varronianæ*, and the names and fragments of the other and doubtful plays are of such a nature that we are unable to draw any conclusions from them. The names of the plays still extant are: 'Amphitruo,' 'Asinaria,' 'Aulularia,' 'Captivi,' 'Curculio,' 'Casina,' 'Cistellaria,' 'Epidicus,' 'Bacchides,' 'Mostellaria,' 'Menaechmi,' 'Miles gloriosus,' 'Mercator,' 'Pseudolus,' 'Poenulus,' 'Persa,' 'Rudens,' 'Stichus,' 'Trinummus,' and 'Truculentus.' The lost play of the twenty-one *Varronianæ* is the 'Vidularia.' The 'Querulus' evidently does not belong to Plautus.

The great number of comedies ascribed to Plautus shows the popularity which his style and manner of treating a subject must have had among his countrymen, and this conclusion is confirmed by the laudatory expressions of the antients themselves. L. Ælius Stilo (Quintil., x. 1) said that if the Muses were to speak Latin, they would adopt the language of Plautus; and Cicero (*De Off.*, i. 29) places Plautus, in respect to the elegance, refinement, liberal feeling, and humour, on an equality with the old Attic comedy. This character is not confined to single passages, but pervades his whole plays. The nature of his humour consists in looking at the bright side of the world in every respect, even under the most unfavourable circumstances. In modern times, with the exception of one or two critics, it is universally agreed that Plautus was one of the first poets of antiquity; and Lessing, to whom we are indebted for the best essay on the life and works of Plautus that has been written in modern times, admits that although he had repeatedly read the 'Captivi' for the purpose of discovering some fault, he never was able to find any, but that, on the contrary, each time he found more reason to admire the play. Horace (*Ad Pisones*, 270) indeed, who was both a sound critic and a great poet, seems to speak with contempt of the verses and the jests of Plautus. But on a close examination of the passage of Horace, it will be found that in reality he only censures his inharmonious verses, and some jests which he thought too coarse for the refined and polished manners of what was called the good society of his own age, which however were a very imperfect standard for estimating the manners described by a dramatist who wrote more than 150 years before him. As for the inharmonious verses of Plautus, they may be excused on this same ground, in addition to which it must be observed that rugged verses and metrical licences in general are much more pardonable in comedy than in any other kind of poetry. But Horace, like Cicero, disliked the early poets of his country.

A question which naturally presents itself with regard to every Roman author is, in what relation did he stand to the Greeks? There is a remarkable passage in Horace (*Epist.* ii.

i, 58, 'Plautus ad exemplar Siculi properare Epicharmi'), which has generally been interpreted as if it implied that Plautus had taken great pains to imitate Epicharmus. But *properare* cannot by any means have this signification: it only expresses the liveliness and rapidity of the dialogue and the action, which are indeed peculiar to the comedies of Plautus; and it must have been this peculiarity in which Horace meant to say that Plautus followed the example of Epicharmus. It is true that we know too little of the works of Epicharmus to prove how far this opinion of Horace is correct; but all we do know of the general character of the Doric poets is in favour of our explanation of the passage of Horace. Moreover we do not find that there existed any similarity either of title or subject between any comedy of Plautus and any one of those of Epicharmus. The old and middle Attic comedies can have served as models to Plautus only in a very general way, as Rome was anything but a proper place for that kind of dramatic poetry; but the new Attic comedy must have exercised a much greater influence upon him, and it is here that we find many plays the titles of which correspond with those of Plautus, though this is no ground for believing that in all instances of this kind he took the Greek drama as his model. The manner in which he treats his characters is one of singular boldness and freedom: they are Greeks, and yet speak and act entirely like Romans; their manners and situations always remind us of Rome: and this is not an accident; but it is evidently the spirit and design of the poet that this impression should be made, for he knew well that the nearer he brought his characters to those of his audience, the greater would be the effect produced; thus Alcmena, in his 'Amphitruo,' is a faithful picture of a Roman matron. Philemon, Diphilus, and Antiphon seem to have been his principal models in single pieces, for some of their plays bore the same or similar titles as some of those of Plautus: others of his plays seem to have had nothing analogous in Greek literature, and may therefore be considered as entirely original. Plautus himself set most value on his 'Epidicus,' as he himself intimates in the 'Bacchides;' and Cicero says that he was particularly partial to the 'Pseudolus' and the 'Truculentus.' But although he has impressed upon all his plays the stamp of his peculiar genius, still there is not one which, in comparison with the rest, does not appear new and striking. His metres are still a matter of great difficulty, but mainly on account of the various readings, and more especially as all the MSS. of Plautus are derived from one which is very corrupt. Some remarks on the subject of the comic metres are given in the article TERENTIUS. A. Mai, in 1815, discovered at Milan a *codex rescriptus*, containing some plays of Plautus, but it is so much mutilated and so illegible, that we cannot hope to derive any considerable benefit from it.

It is well known that there exist a number of spurious scenes in the comedies of Plautus, which, as Niebuhr has shown, were written for the purpose of supplying either actual or imaginary gaps in the original MS. Some of them may be very old and written by skilful hands, but others are very absurd, and betray their modern origin. The scene in the 'Poenulus' which is considered spurious was indeed found by A. Mai in a very old MS. at Milan, but this cannot prove its genuineness, as some of these supplements may have been written even before the fifth century of our æra. Compare the excellent essay of Niebuhr, in his 'Kleine Schriften,' p. 159, ff.

The best among the earlier editions of Plautus are that of Camerarius (Basel, 1558, cum frag. et not. G. Fabricii) and that of J. F. Gronovius (Ludg. Bat., 1664, which was reprinted in 1669, and at Amsterdam in 1684, 2 vols. 8vo.). The recent editions of Bothe (1809-1811, in 4 vols.) and Lindemann are good; the latter especially, who has edited separate plays, has made great progress towards the establishment of a good text. The comedies of Plautus have been translated into almost all the languages of Europe. The Italian literature is very rich in translations of Plautus. Mdme. Dacier published, in 1683, her French translation of the 'Amphitruo,' 'Epidicus,' and 'Rudens.' In 1719 there appeared two complete French translations, the one by Limiers, at Amsterdam, in 10 vols. 8vo., the other by Gueudeville, at Leyden, likewise in 10 vols. 8vo. The Germans have numerous translations of single plays; and there is a translation of all the works of Plautus by Kuffner, published at Vienna, 1806, in 5 vols. 8vo.; and another by G. G. S. Köpke (1809-1820), in 2 vols., which is much better, but not complete. English translations were published, in 1716, by Echard (comprehending the 'Amphitruo,' 'Epidicus,' and 'Rudens'); in 1754, by Cooke; and in 1827, by Cotter. In the last of these translations, which comprehends the 'Aulularia,' 'Epidicus,' 'Menaechmi,' 'Mercator,' 'Pseudolus,' 'Trinummus,' and 'Rudens,' the objectionable passages are omitted. There is an excellent translation by Bonnel Thornton, 'The Comedies of Plautus translated into familiar blank Verse,' Lond., 1767, 2 vols. 8vo. It was continued by Richard Warner, vols. 3 and 4, Lond., 1772, 8vo.; vol. 5, Lond., 1774, 8vo.

PLAYFAIR, JOHN, was born at Benvie in Forfarshire, March 10, 1748. His father was minister of the united parishes of Liff and Benvie, and to him he was indebted for his education till he attained the age of fourteen, when he was sent to the university of St. Andrew. Here he soon became remarkable for his love of study, but more particularly for the rapid progress which he made in mathematics and natural philosophy. There are upon record two proofs of his early proficiency: one consists in the fact that, very few years after his matriculation, Dr. Wilkie, the professor of natural philosophy, finding himself, through indisposition, unable to discharge the duties of his office, delegated them to Playfair. The other is the testimony of George Hill, then a fellow-student of Playfair, and subsequently principal of St. Mary's College, St. Andrew's, who, in a letter to his mother, written during his undergraduateship, and published by his biographer Dr. Cook, very ingenuously observes, 'Playfair has very great merit, and more knowledge and a better judgment than any of his class-fellows. I make *no* exceptions; my parts might be more showy, and the kind of reading to which my inclination led me was calculated to make a better figure at St. Andrew's; but in judgment and understanding I was greatly inferior to him.'

In 1766, when eighteen years old, he distinguished himself as a candidate for the professorship of mathematics in Marishall College, Aberdeen. The examination was a strict one, and lasted eleven days, some say fourteen. The candidates were six in number, of whom two only were judged to have excelled him, namely, the Rev. Dr. Trail, on whom the appointment was conferred, and who attributed his success solely to the disparity of years, and Dr. Hamilton, who subsequently filled the same appointment with much credit.

Upon the death of Dr. Wilkie, in 1772, he offered himself as his successor, but was again unsuccessful; and on this occasion adequate means of determining the relative qualifications of the candidates do not appear to have been resorted to. The same year the responsibility of providing for the support of his mother and her family having devolved upon him by the decease of his father, he considered it his duty to adopt the clerical profession, notwithstanding his intense and growing predilection for scientific pursuits. Having accordingly applied for and obtained the living of Liff and Benvie, he entered, in 1773, upon the duties of his ministry, in the discharge of which and in the education of his younger brethren his time was chiefly occupied during the following nine years. Such a mode of life was not unfavourable to the prosecution of those researches in which he had already engaged with so much avidity. The first fruit of his leisure hours in this respect was a paper communicated to the Royal Society of London, and inserted in their Transactions for the year 1779, 'On the Arithmetic of Impossible Quantities,' which evinced a greater taste for purely analytical investigation than can be conceded to the generality of British mathematicians of that day. The object of the author was to show that 'imaginary expressions are never of use in investigation but when the subject is a property common to the measures both of ratios and angles; that they never lead to any consequences which might not be drawn from the affinity of those measures; and that they are indeed no more than a particular method of tracing that affinity.' (*Works*, iii., p. 28.)

A subject involving difficulties of a higher order had some years previously engaged his attention, while on a visit at Schehallien to witness the experiments of Dr. Maskelyne on the attraction of the mountains in that district, on which occasion he made the acquaintance and acquired the friendship of that astronomer. His investigations upon this subject are contained in his 'Account of the Lithological Survey of Schehallien,' published in the 'London Philosophical Transactions' for 1811.

He resigned his living, in 1782, to superintend the edu cation of the sons of Mr. Ferguson of Raith; and in 1785 he was appointed professor of mathematics, jointly with Dr. Adam Ferguson, in the university of Edinburgh, an appointment previously held by Dugald Stewart. In 1789 he succeeded Dr. Gregory as secretary to the physical class of the Edinburgh Royal Society; and about the same time, owing to the illness of Dr. Robison, the duties of general secretary and the labour of arranging the Society's memoirs for publication devolved chiefly upon him, but the nominal appointment of general secretary was not conferred upon him till the death of Dr. Robison, in 1805, whom he likewise succeeded as professor of natural philosophy in the university of Edinburgh. This obliged him to resign the chair of mathematics, on which occasion the mathematical class expressed their sense of the obligation they were under for his past exertions in their behalf by presenting him with a valuable astronomical circle, now in the observatory of the astronomical institution. The dispute which followed the nomination of Mr. Leslie to the vacant chair has been already noticed under LESLIE.[*] The extreme illiberality of the measures adopted by Mr. Leslie's opponents, and the manifest desire of the clergy to cripple scientific emulation by restricting to their own class appointments totally unconnected with theology, and hitherto filled by laymen with honour and advantage, roused the indignation of Mr. Playfair, who exposed 'the new-sprung zeal for orthodoxy,' in a satirical pamphlet published at Edinburgh in 1806, under the title of a 'Letter to the Author of the Examination of Mr. Stewart's short statement of Facts relative to the Election of Professor Leslie.'

His intimacy with Dr. James Hutton led to his becoming a strenuous supporter of the geological theory which bears his name. His 'Illustrations of the Huttonian Theory of the Earth,' Edin., 1802, 8vo. (*Works*, vol. i.), have been greatly admired for the clearness with which the system itself is there for the first time unfolded, and for the manner in which he examines the several arguments that had been adduced against it; but although, as is remarked by a contributor to the 'Encyclopædia Britannica,' the 'fastidious critics of France' may have acknowledged that 'Mr. Playfair writes as well as Buffon, and reasons incomparably better,' it has justly been a matter of regret that talents such as his should have been employed for so many years upon a subject relative to which the requisite data had not been collected for coming to either useful or satisfactory conclusions. Of the necessity of more extensive observation Mr. Playfair was fully aware; and, besides many journeys undertaken for the purpose of examining the geological features of his own country, immediately after the restoration of peace, in 1815, he set out upon a geological tour through France, Switzerland, and Italy, in search of material for an enlarged edition of his 'Illustrations,' which however other occupations prevented him from maturing for the press.

Shortly after his death, which took place at Edinburgh, 19th of July, 1819, Dugald Stewart, in a letter to Mr. Playfair's nephew and biographer, observes, 'As to those features of his character which are less known to the public, a faithful and perfect resemblance is preserved in the masterly portrait of Mr. Jeffrey, which you will no doubt add to your memoir.' The article here alluded to will be found under the notices of Playfair, in the 'Annual Biography' for 1820, and in the 'Encyclopædia Britannica.' To it we refer the reader, confining ourselves to the extracts which follow. 'He possessed in the highest degree all the characteristics both of a fine and powerful understanding; at once penetrating and vigilant, but more distinguished perhaps by the caution and success of its march than by the brilliancy or rapidity of its movements.' 'As a teacher he took care to imbue the minds of his pupils, from the very commencement of their study, with that relish for the truths it disclosed, and that high sense of the majesty with which they were invested, that predominated in his own bosom, ... and formed them betimes to that clear, masculine, and direct method of investigation by which, with the least labour, the greatest advances might be accomplished.' 'As an author, he wrote slowly; his first sketches were often slight and imperfect, his chief effort and greatest pleasure consisting in their revisal and correction. The outline being complete, he could proceed with the filling in to an almost indefinite extent, enriching and improving as long as he thought fit, without risk of destroying the proportions or injuring the harmony and unity of the design, and without waiting for favourable moments of peculiar alacrity. In his conversation, so far was he from wishing to set off what he had to say by any brilliancy or emphasis of expression, that it seemed generally as if he had studied to disguise the weight and originality of his thoughts under the plainest form of speech and most quiet and indifferent manner; so that the profoundest remarks and subtlest observations were often dropped, not only without any solicitude that their value should be observed, but without any apparent consciousness that they possessed any.'

From the year 1804 he was a frequent contributor to the 'Edinburgh Review,' and most of his articles in that periodical still possess considerable value. They are—1, Review of Mudge's 'Trigonometrical Survey,' v., 1805; 2, Review of Mechain and Delambre, 'Base du Systême Metrique Decimale,' ix., 1807; 3, Review of Laplace, 'Traité de Mecanique Céleste,' xi., 1808; 4, Review of 'Le Compte rendu par l'Institut de France,' xv., 1809; 5, Review of Lambton's 'Indian Survey,' xxi., 1813; 6, Review of Laplace, 'Essai philosophique sur les Probabilités,' xxiii., 1814; 7, Review of Baron de Zach, 'Attraction des Montagnes,' xxvi., 1816; 8, Review of 'Kater on the Pendulum,' xxx., 1818. The whole of these are reprinted in the fourth volume of the collected edition of his works, published at Edinburgh in 1822, in 4 vols. 8vo., to which is prefixed a memoir of the author by Dr. James G. Playfair. To the 'Encyclopædia Britannica' he contributed the articles 'Æpinus' and 'Physical Astronomy,' and an incomplete 'Dissertation on the Progress of Mathematical and Physical Science since the Revival of Letters in Europe' (*Works*, vol. ii.). The proofs of this were under revisal at the time of his death. His contributions to the 'Transactions of the Edinburgh Royal Society' are: 1, 'On the Causes which affect the Accuracy of Barometrical Measurement,' i., 1788 (*Works*, vol. iii.); 2, 'Life of Matthew Stewart,' i., 1788 (*Works*, iv.); 3, 'Remarks on the Astronomy of the Brahmins,' ii., 1790 (*Works*, iii.); 4, 'On the Origin and Investigation of Porisms,' iii., 1794 (*Works*, iii.); 5, 'On the Trigonometry of the Brahmins,' iv., 1798 (*Works*, iii.); 6, 'Theorems relative to the Figure of the Earth,' v., 1805 (*Works*, iii.); 7, 'Biographical Account of the late Dr. James Hutton,' v., 1805 (*Works*, iv.); 8, 'On the Solids of greatest Attraction,' vi., 1809 (*Works*, iii.); 9, 'On the Progress of Heat in spherical Bodies,' vi., 1812 (*Works*, iii.); 10, 'Biographical Account of Dr. John Robison,' viii., 1815 (*Works*, iv.); 11, 'On the Naval Tactics of the late John Clerk, Esq.,' ix., 1821 (*Works*, iii.). His separate works not already mentioned are:—1, 'Elements of Geometry,' Edin., 1795, 8vo.; it contains the first six books of Euclid, the elements of plane and spherical trigonometry, and a supplement on the geometry of solids and the quadrature of the circle, and has passed through four editions since it ceased to be used as a text book in the university of Edinburgh. 2, 'Outlines of Natural Philosophy,' Edin., 1812 and 1816, 2 vols. 8vo. This contains the heads of lectures delivered by the author at the university of Edinburgh. Merely the enunciations of the several propositions and the formulæ as adapted to practical application are given, but reference is made to other works, where the demonstrations will be found. The first volume comprises statics, dynamics, hydrostatics, hydraulics, and pneumatics; the second refers wholly to astronomy; a third volume was contemplated to comprise optics, electricity, and magnetism, but was never executed.

(The collected edition of Playfair's *Works;* the articles 'Playfair' in Brewster's *Cyclopædia* and in the *Encyclopædia Britannica;* the *Annual Biography and Obituary,* 1820, vol. iv., pp. 371-390; Chambers's *Biographical Dictionary of eminent Scotsmen,* vol. iv.)

PLAYHOUSE. [THEATRE.]

PLEA. [PLEADING.]

PLEADING at Common Law. Pleadings are the allegations of the respective parties to a cause expressed in technical language. In order that a correct decision may be made upon disputed rights, it is necessary that the points to be decided should be clearly ascertained, and this is effected by the system of special pleading, by which the precise points in controversy are presented for decision, unencumbered with extraneous matter.

Actions are commenced either by writ or by plaint: by writ, if the court in which the action is brought cannot take cognizance of a complaint without an act of the royal authority in the particular cause; by plaint, if the court is authorised to proceed without royal interference. This writ till lately issued out of chancery, and was called the original writ, by which name it was distinguished from process issued, after the commencement of a cause, by the court which the original writ had authorised to take cognizance of the cause. The original writ or plaint stated the nature of the complaint shortly, though more fully in some forms of actions than in others. After the defendant appeared in court to answer the proceedings against him, he was entitled, within a certain time, to receive from the plaintiff a more detailed statement of the nature of the complaint. This statement was called the declaration, *narratio*, or count, though the last of these terms is now more commonly used to denote one of several distinct matters of complaint comprised in the same declaration.

---

[*] In that article the date of Mr. Leslie's promotion to the chair of natural philosophy is incorrectly given; instead of 1809 it ought to have been 1819.

Within a certain number of days, varying according to circumstances, after the delivery of the declaration, the time for pleading arrives; the term 'pleading' being not only used in the extensive sense mentioned above, but also in the limited sense of the answer, whether consisting of statement or of denial, which is made by the defendant to the declaration. In answering the declaration, the defendant is not allowed to accumulate his objections both of law and of fact in one defensive pleading. The peculiarity of our system in referring matters of fact to the decision of an unprofessional tribunal, and of leaving questions of law only to the judges, has created a necessity for separating the matters of law from those of fact, and of presenting the latter in a shape in which they can be readily understood by persons who are not lawyers by profession. It is to the severe analysis required by this feature of our jurisprudence that the system of special pleading is probably indebted for its excellence.

When called upon to plead, the defendant has several courses open to him. First, he may admit the complaint set out in the declaration either by express acknowledgment or by silence. In either case the court pronounces judgment against him: in the former case, upon his cognovit actionem, or confession; in the latter, upon his default, or, as it is termed, by nil dicit, those being the words by which the default of a defendant was formerly recorded. Or, secondly, he may decline to answer the charge contained in the declaration, on the ground that the court has not jurisdiction of the matter; or that the plaintiff is not entitled to sue, as being an outlaw, foreign enemy, or the like; or that the defendant is incapable of being sued, as being an infant, or incapable of being sued alone, as a married woman without her husband, or incapable of being sued alone, as a party to a contract which forms the subject of the action, when he is sued without his co-contractor being made a co-defendant in the action; or that the plaintiff or the defendant is misnamed. This is called pleading in *abatement*, because the defendant prays that the court will abate (put down) or quash the proceedings. Or, thirdly, the defendant admitting, for the present purpose at least, that the facts stated in the declaration are true, may insist that these facts give the plaintiff no cause of action against him; he may accordingly rest (demur) upon the facts as they appear in the declaration, and call upon the court to give judgment in his favour upon that state of facts. This form of pleading is called a 'demurrer.' Or, fourthly, the defendant may answer the complaint, or, as it is technically called, he may 'plead to the action;' and that in one of two ways: he may deny some material allegation in the declaration which is necessary to the maintenance of the action; and, before the rules of pleading promulgated in 1834, he might in a great variety of actions, and those of the most common occurrence, plead one sweeping denial of the whole declaration;—this was called pleading the 'general issue,' which is now permitted in those actions only in which it is expressly authorised by statute, several acts of parliament having allowed defendants who are engaged in carrying into effect some public object to plead the general issue, and under that plea even to enter into matters of defence which are inconsistent with such a denial. A plea denying either one or all of the allegations in the declaration must 'conclude to the country,' that is, the defendant must state his readiness to submit to the decision of a jury (who are called 'the country,' as contradistinguished from the 'court') the truth of the matter of fact asserted in the declaration and denied in the plea. It is the same if the plea asserts a fact denied in the declaration and in either case the defendant is said to *take issue*.

The second mode of 'pleading to the action' is by putting in a 'special plea,' which either expressly, or, according to modern practice, tacitly, admits the truth of the allegations contained in the declaration, but which not only confesses but also avoids them. The special plea (whence the whole system is often called 'special pleading') introduces some new fact or facts, the effect of which, if true, is to show that notwithstanding the facts alleged in the declaration, the plaintiff is not entitled to maintain his action. As it is yet uncertain whether the plaintiff will deny this new matter or will admit it to be true, there can be no conclusion to the country upon such a plea, but the defendant prays the judgment of the court in his favour, in anticipation of the new matter alleged being admitted or proved; and if that new matter contain an affirmative proposition, the defendant must conclude his plea with a verification, that is, an offer to prove it *if* its truth should be controverted on the other side. This is called 'tendering an issue.'

The next pleading on the part of the plaintiff will be regulated by the course pursued by the defendant. If the defendant has confessed the action or made default, the plaintiff has nothing to do but to pray that the court will pronounce a judgment agreeable to the confession, or one consequent upon the default. If the defendant has pleaded in abatement, the plaintiff either acquiesces in the action being quashed, or he demurs to the plea as not showing sufficient matter for quashing the proceedings, or he replies to the plea either by taking issue (*denying*) some material allegation in the plea, or by confessing and avoiding the plea, alleging some matter which, *consistently with* the truth of the plea, destroys its effect and shows that the proceedings ought not to be quashed. If the plaintiff demurs to the plea in abatement, the defendant must either abandon that plea and put in a plea to the action, or he must join in demurrer. If, upon the argument of the demurrer, the court are of opinion that the plea in abatement is good, they give judgment that the proceedings be quashed: if they are of opinion that the plea is bad, the judgment is, that the defendant answer over (quod respondeat ouster), in other words, that he plead to the action.

If the plaintiff take issue upon the plea in abatement, the defendant is bound to join issue, that is, to accept the mode of trial offered, and if upon a trial the issue be found for the defendant, he has judgment that the proceedings be quashed; but if the verdict be for the plaintiff, the judgment is, not that the defendant answer over, but that the plaintiff recover his demand against the defendant.

If the defendant has demurred to the declaration, the plaintiff either abandons the action or he applies to the court for leave to amend his declaration; or he joins in demurrer, asserting that the declaration is sufficient to support the action. This demurrer and joinder form 'an issue in law,' or a question between the parties to be decided by the court after hearing the matter of law argued on both sides.

The plaintiff's answer to the defendant's plea, whether in abatement or in bar, is called a replication. If the defendant has taken issue, by pleading in denial of part or of the whole of the declaration, the plaintiff must join issue, which is done by adding to the defendant's appeal to a jury the words 'and the plaintiff doth the like,' formerly 'et querens inde similiter,' whence this step is called 'adding the similiter.' If the defendant has pleaded specially, the plaintiff may either take issue upon the new matter alleged, and conclude to the country, or he may plead new matter, thus in his turn confessing and avoiding the defendant's plea. Whenever in the course of the pleading in a cause one party takes a proper issue upon an allegation of his adversary, that adversary is bound to join issue and go to trial before a jury; but when, instead of taking issue, new matter is pleaded, the adversary has the option of taking issue upon that new matter, of confessing and avoiding it, or of demurring to it. As the pleadings may thus go on through several more stages, names have been devised for those which most frequently arise. The defendant's answer to the plaintiff's replication is called a rejoinder; the plaintiff's answer to the rejoinder is called a surrejoinder; the defendant's answer to the surrejoinder is a rebutter; and the plaintiff's answer to the rebutter is a surrebutter. The proceedings might go on ad infinitum, but for a very salutary rule which forbids a party from alleging anything inconsistent with, or even not corroborative of, his previous pleading. A violation of this rule is called 'a departure in pleading,' and is attended with fatal consequences to the party guilty of it.

The above is a short and necessarily incomplete sketch of the course of pleading at common law, without defining the strict rules by which the altercations between the parties are carried on, the object of which is to develop the precise points in controversy between parties, and to present them in the most convenient shape for decision. Of these rules Lord Mansfield observes: 'The substantial rules of pleading are founded in strong sense and in the soundest and closest logic, and so appear when well understood and explained; but by being misunderstood and misapplied, are often made use of as instruments of chicane.' The object of most of the new rules of pleading has been to prevent this misapplication as well as to lessen expense, though, as might be expected, in order to avoid an evil practically felt, restrictions have been introduced which are found to be productive of as much inconvenience as that sought to be remedied.

Where a point is raised which is found to consist wholly or principally of matter of fact, the parties, provided there has been a correct application of the rules of special pleading, are distinctly apprised by the pleadings of the exact nature of the question to be decided by a jury, and are thus enabled to direct their attention to that question, and prepare their proofs with reference to that question only. If the point in controversy is found to resolve itself into a question of law, a decision may be obtained by submitting the matter to the opinion of the court after argument upon demurrer, without the trouble, expense, and hazard of a trial before a jury.

We possess very little information as to the mode of pleading before the Conquest. At or soon after that period an important revolution took place. The pleadings in the Aula Regia, and afterwards in the courts which branched out of it, appear to have been conducted vivâ voce in the French language, by Norman advocates called 'cauntours.' After a discussion before the court as to the proper form of pleading [SERJEANTS] before the judges, the pleadings were minuted down by the officers of the court in the form in which they had been finally agreed upon. Thus, little or no inconvenience arose from the prohibition which existed against the making of any alteration in the pleadings after they were entered. In the reign of Edward III. the pleadings were directed to be carried on in English, and the entries of these pleadings to be in Latin. Afterwards a custom was introduced of preparing the pleadings out of court and delivering them to the officers to be entered. In consequence of this arrangement defects in pleadings were not discovered until a period at which the parties were bound by them as being entered, and it became necessary for the legislature to interfere in order to allow amendments to be made in some cases, and in others to direct the judges to pronounce judgment without regard to formal objections. By the late rules all pleadings must be *delivered* by the one party to the other. (Blackstone's *Comm.;* Report of *Comm. Law Commission.*)

PLEADING IN EQUITY. The following remarks may serve to show how far Pleadings in Equity differ from Pleadings at Law, from which they are derived; and they may be taken as supplemental to the article EQUITY, in which a reference is made to this article. Some little repetition can hardly be avoided.

The Answer in Equity differs materially from the answer at Law, in being upon oath, except in the case of persons who have privilege of peerage, and in the case of a corporation; and the plaintiff may use the whole of the defendant's answer as evidence against him at the hearing of the cause, or such integral part of it as he may think proper. He may also, by means of the admissions contained in the answer, obtain the inspection of books, papers, and writings in the defendant's possession, which support his (the plaintiff's claim), and he may use them as evidence at the hearing of the cause. The defendant, except on the question of costs, can make no use of his own answer, further than as showing what his defence is; and he must support this defence by evidence, just in the same way as the plaintiff must prove those parts of his case which he cannot prove by the admissions in the defendant's answer. Any number of plaintiffs may join in a suit, if they have all a common interest, however unequal in value, in the subject-matter of the suit; and a common interest means such a legal or equitable title to the subject-matter of the suit, or to some part of it, as will entitle them to a decree which shall affect the defendants. All the plaintiffs in a suit are considered one, as appears from the general rule that a suit is abated by the death of a plaintiff or the marriage of a female plaintiff; and also from the rule that a person who has no interest in the subject of the suit cannot join as a plaintiff with one who has. But the suit is a different suit against each defendant, for each defendant may answer separately to the bill; and no defendant is affected in any way by the answer of a co-defendant. If a defendant dies, the suit abates as to him, but continues as to the other defendants, though it is nearly always necessary to restore the integrity of the suit by making the personal representative or the heir at law of the deceased defendant a party to it.

The writ of Subpœna is the original process by which a party is brought before the court. This writ formerly required the person to whom it was addressed to appear and answer the complainant's bill under a penalty of 100*l.* The present form of Subpœna requires the person to whom it is addressed to appear and answer 'upon pain of an attachment issuing against his person, and such other process for contempt as the court shall award.' Those who have privilege of peerage are required to appear and answer by a Letter Missive from the lord chancellor.

Every person who files a bill is entitled to have a subpœna, and the person who has been served with such subpœna is bound, within a time fixed by the rules of the court, to demur, plead to, or to answer such bill. The origin of this writ of subpœna, or at least the adoption of it in a court of equity, is usually attributed to John Waltham, bishop of Salisbury, master of the rolls in the reign of Richard II.

The bill is briefly and sufficiently defined to be 'a declaration in writing, showing the plaintifes griefe, and the wrong which he suposeth to bee done unto him by the defendant, and what damages he sustaineth by occasion thereof, praying process against him for redresse of the same.' (West, *Simboleography*, 194, ed. 1622.) 'And first the matter of every bill ought to be true. Secondarily, the same matter ought to be laid down therein plainly and certainly in every circumstance of the thing, person, time, place, manner of doing, and other accidents. And thirdly, the same ought to be sufficient in law, both for the forme thereof, and for the matter, that it be such as is examinable in this court; which being otherwise, may be dismissed thence.' (West.)

A bill then is a declaration in writing of a complainant, or of several complainants who have such a common interest as may form the subject of one suit. Like a declaration at law, it contains the claim of the plaintiff and the grounds thereof. In form it is, as already observed, a petition or supplication: as it commences with words of supplication, so it concludes with a prayer for relief and a prayer of subpœna against the persons from whom the plaintiff claims relief, in order to compel them to appear and answer the bill, and those only are made defendants to the complainant's bill against whom he prays for a subpœna; and all persons who have an interest in the matter of the suit must either be complainants or defendants. This general rule is in practice attended with great difficulty, inasmuch as the word 'interest' is somewhat vague; but it means either a legal or equitable title or claim to that which is the matter of the suit, or to some part of it. In cases of fraud, a person may be a party to a suit, whose only interest in the matter is his liability to pay costs.

According to present practice, a bill has become a much longer declaration than formerly, which is partly owing to the more complicated nature of modern transactions, and partly to other causes. It is divided into various parts by modern writers, but in effect it only contains two parts, the declaration of the grievance and the prayer for relief. The declaration consists of what are technically called Statements and Charges; the statements are or ought to be a clear exposition of the facts on which the plaintiff founds his title to relief; and every fact which is necessary, either by itself or coupled with other facts, to support the plaintiff's prayer, should be sufficiently alleged. This rule, though it may appear vague, and would be useless to any person who attempted to draw a bill without experience in such matters, really contains all that can be said in general terms.

The statements of a bill are usually followed by charges, which are not a mere repetition of the statements, but contain certain things or facts either already stated and alleged in the charges with more particularity for the purpose of obtaining an admission from the defendant, or they contain new facts of which in like manner the plaintiff wishes to obtain an admission as evidence in support of his statement and his prayer for relief. It is also usual in the charges to suggest the defendant's grounds of defence, for the purpose of ascertaining what they are, and generally to make all such charges as, if admitted or proved, would sustain the plaintiff's claim against the defendant. Another object is to discover what defence the defendant will make. But the main purpose of the charges is to obtain from the defendant what is technically called discovery, that is, evidence in support of the plaintiff's claim, either by the admissions in the defendant's answer, or from written papers in the possession or power of the defendant. This is the great distinction in present practice between a declaration at law and a bill in equity. Both state the plaintiff's demand and the foundation of it; but the bill in equity also contains a large part of what, if proved, would be the plaintiff's evidence. Now much of this matter which is charged in a bill may be and often is entirely false, and is invented by the plaintiff for the purpose of seeing whether he cannot extract some evidence favourable to himself from the defendant. The plaintiff may invent or suggest as much false matter as he pleases, but it must be matter of that kind, which, if true, would give him a right to that which he demands of or against the defendant. Now the defendant must answer all that the plaintiff distinctly alleges in his bill, provided it be material to the plaintiff's case, or he must demur or plead to it; and he cannot demur, in the case supposed, because he thereby admits the plaintiff's case to be true, and therefore he must admit that the plaintiff is entitled to the relief which he prays. Thus the plaintiff, by means of the right which he has to compel an answer, incidentally may obtain the discovery, that is, the evidence, which he wishes to have. If the defendant can plead to the bill, he is not bound to answer beyond the plea; for a good plea is a complete answer to the whole bill, or to such part of the bill as it extends to.

The interrogatories, which follow the charges in a bill, are no necessary part of it; but they are added because they are useful in obtaining a more particular answer from the defendant. [Equity.]

'An answer is that which the defendant pleadeth or saith in barre to avoid the plaintiff's bill or action, either by confession and avoiding, or by denying and traversing the material parts thereof.' (West, 194.) Thus it appears that an answer in equity is in form the same as a plea to the action at law. It must be a complete answer to everything sufficiently alleged and charged in the bill, at least to everything that is material to the plaintiff's claim. Formerly, if the defendant made an imperfect answer, 'then, upon demurrer tendered and motion made in court by the plaintiff's counsel, showing the imperfection of such answer, an order will be made that the defendant shall make a better answer by some certain time, and thereupon issueth a subpœna ad faciendum meliorem (sic) responsum.' (West, 187.)

The mode of proceeding in the case of an insufficient answer has been already explained. [Equity.]

A defendant, as already observed, must in proper form and in due time, as prescribed by the rules of the court, answer the bill upon oath, unless he has privilege of peerage, or be a Quaker, or other person who is excused from taking an oath, in which case his statement on honour in the case of those who have privilege of peerage, and in the other case his solemn affirmation, is sufficient. But the plaintiff may consent to take the answer without the defendant's oath or signature, which is sometimes done. Those who are not Christians must swear to the truth of their answer in such form as the religion which they profess declares to be a binding form.

A plaintiff may amend his bill either before answer or after; that is, he may strike out parts and insert new parts; and it is not easy to say what are the limits to the amount of alteration. A defendant cannot alter his answer, it being a statement upon oath, but he is nearly always required, and may always, whether he is required or not, answer the amendments in the bill in such way as he shall think best for his defence.

A demurrer in equity needs little explanation further than what has been given. [Equity.] When it is a demurrer to the whole bill, which is the most usual kind of demurrer, the object generally is to get rid of the suit, and to avoid an answer which may give the plaintiff some discovery. If the demurrer is allowed, the suit is properly at an end; but leave is often given to the plaintiff to amend his bill, particularly where the demurrer is for want of proper parties. If the demurrer is overruled, the plaintiff must answer the bill.

A plea in equity may require a few words of explanation. A plea in bar to the whole bill, which is the common kind of plea, is an averment which is offered as a substantial answer to all the statements and charges in the bill, though it is not in form such an answer. In fact, a plea in equity is the same thing as a plea at law: it is the defendant's answer to the whole of what is adversely alleged, and as it does not in terms answer all that is adversely alleged, it must be taken to admit that to be true which it does not in terms answer, because the averments of the plea are offered as a complete answer to the bill. In the old books there is no distinction made between a plea in equity and an answer in equity; nor is there any difference substantially. 'A plea is a special answer to a bill, differing in this from an answer in the common form, as it demands the judgment of the court in the first instance whether the matter urged by it does not debar the plaintiff from his title to that answer which the bill requires.' (Lord Redesdale, in *Roche* v. *Morgell*, 2 S. and L., p. 724.) Now, as a complete answer is that which the plaintiff requires, and is entitled to if his bill is good in substance and form, and as discovery is in many cases his chief object, and in some cases his only object, it is evident that before any further proceedings can be taken in the matter of a bill to which a defendant pleads, it must be determined whether the plea is good in form: and for this purpose the averments of the plea must be considered as true; and all that part of the bill must also be considered as true to which the plea is no direct answer.

Now, the plea is good in form if it contains averments which either directly negative all the allegations in the bill that give the plaintiff a title to relief against the defendant, or positive averments which destroy the effect of such allegations. The plea is bad in form if the averments of the plea, though true (as on arguing the formal goodness of the plea they are assumed to be), are not a complete answer either by negation or affirmation or both, to all the allegations in the bill which give the plaintiff a title to that which he demands of or against the defendant. The formal badness of such plea is a necessary consequence of the admitted truth of all those parts of the bill to which the averments of the plea do not extend. In order therefore that a plea may be taken as a sufficient answer to the whole bill, it must contain sufficient averments to negative or displace all the allegations in the bill which, if true, give the plaintiff a title to relief. But inasmuch as a plea is an answer, the defendant must, in addition to the averments, give an answer upon oath to all those statements and charges in the bill which, if true, would destroy the effect of the matter pleaded; and this is called supporting a plea by an answer, which is generally necessary. If the plea is decided to be good in form, then the truth of the plea alone is in issue between the plaintiff and defendant, and the cause is heard on the issues so joined; just as, in the case where the bill is answered, the cause is heard upon all the issues of law and fact joined by such bill and answer. If a plea is simply overruled, the defendant must answer the bill. If it is overruled, the answer in support of the plea, if there is one, may serve for an answer as far as it goes, and the court may accordingly order it to stand for an answer to such part of the bill, with liberty to except to it or not, according as it may be an insufficient or sufficient answer to that part of the bill to which it extends.

The matter pleaded as an answer to the bill must be one thing, and such a thing as is an answer to the whole of the plaintiff's demand, or to so much of the bill as the plea extends to. The defendant cannot, according to the rules of equity pleading, plead in bar several and distinct matters, any one of which would be an answer to the bill. But if the averments are averments of separate facts which form one material fact, such averments make a good plea; which is thus expressed by lord Eldon:—'The office of a plea generally is not to deny the equity, but to bring forward a fact which, if true, displaces it; not a single averment, as the averment in this answer, that no bill of sale was executed, but perhaps a series of circumstances forming in their combined result one fact which displaces the equity.' (Lord Eldon, *Rowe* v. *Teed*, 15 Ve., 377.)

The definition of a plea 'not denying the equity, but bringing forward a fact which, if true, displaces it,' is in substance the same as the definition of an exceptio by Gaius (iv. 119):—'Omnes exceptiones in contrarium concipiuntur, quia adfirmat is, cum quo agitur.'

A defendant may disclaim all interest, right, or title in or to the matter of the plaintiff's bill; but it will nearly always happen that such disclaimer will be an insufficient answer by itself, and that there will be parts of the bill to which it will be necessary to give an answer. Accordingly a disclaimer is accompanied by an answer to some part of the bill at least.

A defendant may demur to a part of a bill as well as to the whole bill: he may also plead to a part of a bill as well as to the whole bill; and he may demur, plead, answer, and disclaim, with respect to the same bill. But it is very rare that any two of these ways of pleading are united, except an answer and disclaimer, on account of the practical difficulty attendant on such a mode of defence. For it follows from the nature of these ways of pleading that they must severally apply to substantially different parts of the bill. A man cannot plead to that matter to which he demurs; for to plead is to offer something as an answer sufficient in substance, though it may not be so in form, and to demur is to allege that he ought not to answer. For the same reason he cannot answer, in the formal manner of an answer, to that to which he has either pleaded or demurred, having by pleading already offered something as a sufficient answer, and having by demurrer alleged that he ought not to answer. 'A plea or answer will therefore overrule a demurrer, and an answer a plea; and if a disclaimer and answer are inconsistent, the matter will be taken most strongly against the defendant upon the disclaimer.' (Mitford, p. 320.)

Pleadings in equity were formerly continued, like pleadings at law, beyond the bill and answer. The plaintiff replied to the defendant's answer by his replication, which is defined to be 'the plaintife's speech or answer to the defendant's answer, which must affirm and pursue his bill, and confesse and avoid, denie or traverse the defendant's answer.' (West.) Thus if the answer denied the plaintiff's claim as stated in the bill, and suggested or stated some new matter, it was necessary for the plaintiff to make a special reply which was analogous to the defendant's answer. To meet this special replication, the defendant put in a rejoinder, which is defined to be 'the answer which the defendant maketh to the plaintif's replication, which must pursue and confirm his answer and not swarve from the same, and sufficiently confesse and avoid, denie or traverse each material part of the plaintif's replication. If the parties be not at issue by reason of some new matter disclosed in the defendant's rejoynder that requireth answer, then may the plaintif surrejoyne to the said rejoynder, and the defendant in like manner to the surrejoynder, if there be cause, which hapneth verie seldome.' (West.)

This method of pleading by special replications and rejoinders is now disused, and all the objects of such proceedings are at present attained by the power which the plaintiff has of amending his bill and stating his case in a better form after he has seen the defendant's answer. The disuse of special replications has also led to the practice of frequently stating the plaintiff's case more completely in his bill in the first instance, and introducing numerous charges and suggestions. Thus if the plaintiff anticipates that the defendant may plead to his bill, and so prevent him from obtaining the complete answer which he wishes, he will charge various matters in his bill which will destroy the effect of the anticipated plea, unless the defendant supports his plea by a full answer to such matters.

But whether a bill has been pleaded to or answered, the plaintiff and defendant are not at issue until the plaintiff has filed a replication and served upon the defendant a subpœna to rejoin. This is now merely a formal matter, but t is still necessary in order to put the cause at issue, and to enable the parties to proceed to the examination of witnesses in support of the allegations of their respective pleadings. [Evidence.]

The form of pleading used in this country is derived from hat of the Romans. In Bracton's work, the fifth part, which is entitled 'De Exceptionibus,' occupies the same place in his treatise as the same matter does in the Institutes of Gaius and of Justinian, and the terms used by Bracton are those of the Roman law: indeed, the whole work of Bracton follows the method and order of Justinian's Institutes. A comparison between the Roman and English procedure in equity is made in Gilbert's 'Forum Romanum.'

After the Legis Actiones among the Romans fell into disuse, the mode of procedure was per formulas, the nature of which is fully explained by Gaius (iv. 39, &c.). The Demonstratio was that part of the formula which showed the matter upon which the plaintiff's demand was founded; the Intentio contained the demand; the Adjudicatio gave power to a judex to decide on the matters in dispute; and the Condemnatio empowered him to make a decree in favour of the plaintiff, or to dismiss the defendant, according to the evidence produced before him. The formula was a proceeding in jure, that is, before the prætor, and it contained the instructions to the judex, to whom, according to Roman practice, the investigation of the facts and the ministerial duty of pronouncing the decree were entrusted. The answer of the defendant to the plaintiff's claim was called Exceptio, and exceptiones were either peremptoriæ—in bar, or dilatoriæ—in abatement. The plaintiff might answer the defendant's plea by his Replicatio, and the defendant might answer the Replicatio by a Duplicatio, to which the plaintiff might answer by a Triplicatio; 'and the practice of all such pleadings,' says Gaius (iv. 129), 'has been sometimes carried even farther than this, owing to the multifarious character of the matters in dispute.'

One example may be sufficient as an instance of the Roman pleading. 'If an argentarius sue for the price of a thing sold by public auction, the form of the defendant's plea may be a submission to have judgment against him, provided (si) the thing which was purchased has been delivered to him; and this is a good plea (exceptio). But if the conditions of sale were that there should be no delivery till the money was paid, the argentarius may put in a replication to this effect, submitting to the plea, unless (nisi) the conditions of sale were that the thing should not be delivered to the purchaser before he had paid the money.' (iv. 126.) The words *si* and *nisi*, which are used in this passage, were introduced merely for the purpose of adapting the pleadings for insertion in the formula; for the Condemnatio in the formula was conditional; that is, if so and so is proved, then make such and such a decree against the defendant; and if not proved, dismiss the defendant.

PLECO'TUS. [Cheiroptera, vol. vii., p. 25.]

PLECTRO'PHANES. [Fringillidæ.]

PLECTRO'PHORUS, M. de Férussac's name for a genus of Testaceans which may have been slug-like animals (*Limax*), carrying on their tails, and at a distance from the buckler, a kind of small conical shell; but Cuvier observes that they are only known from the not very authentic figures of Favanne.

PLEBEIAN, PLEBES. [Rome.]

PLEDGE is a thing bailed (delivered for a temporary purpose [Bailment]) as a security to the bailee for the performance of some engagement on the part of the bailor. When the pledge is for a debt, more especially where it is given to secure a loan at interest, it is commonly called a pawn. [Pawnbroker.] In bailments the degree of care required from the bailee varies according to circumstances. When the bailment is for the sole benefit of the bailee, he is bound to use the greatest care, and is excused by nothing but unavoidable accident or irresistible force. When the bailment is for the mutual benefit of bailor and bailee, the latter is bound to take the same care of the thing bailed as a prudent man usually does of his own. When the bailment is for the sole benefit of the bailor, it is sufficient if the bailee keep the goods bailed as carefully as he does his own, however negligent he may be. Different writers on the law of bailments refer the contract of pledge to each of these divisions. Perhaps the conflicting opinions may, to a certain extent, be reconciled by distinguishing between the different objects which the pledge is intended to secure, and the engagements which it is intended to protect. First, the pledge is sometimes, though rarely, given for the sole benefit of the pledgee, as where, after a contract is completely made, one party gives to the other a pledge for its performance. Secondly, which is the ordinary case, the pledge may be for the mutual benefit of bailor and bailee, as in the case of a loan of goods on hire or of money at interest, accompanied by a pawn, in which case the pawn gives security to the bailee, and purchases credit for the bailor. Thirdly, the pledge may be given for the purpose of obtaining a gratuitous loan of goods or of money, or of procuring some other advantage to the bailor only. It would appear that in the first of these three cases the bailee would be liable for the consequences of slight negligence; in the second, for the consequence of the want of ordinary care; and in the third, for gross negligence only.

The pledgee is bound to return the pledge and its increments, if any, upon being requested so to do, after the performance of the engagement. This duty is extinguished if the pledge has ceased to exist by some cause for which the pledgee is not answerable. But he is responsible for all losses and accidents which happen after he has done anything inconsistent with his duty as pledgee, or has refused to do his duty. When the full amount of the debt or duty therefore is tendered and refused, and the pledge is detained, the pledge is at the sole risk of the pledgee: so if the pledgee misuse the pledge. In every case where the pledge has sustained injury from the wrongful act or default of the pledgee, the owner may recover damages to the amount of the injury, in an action on the case. By the act of pledging, the pledgor impliedly warrants that the property is his own, and such as he can rightfully pledge.

The contract of pledge may be extinguished by the performance of the engagement for which the pledge was given, or by satisfying the engagement in any other manner, either in fact or by operation of law, as by the acceptance of a higher security without an express stipulation that the pledge shall continue.

If the engagement, to protect which the pledge is given, be not performed within the stipulated time, the pledgee may sell, upon giving due notice to the pledgor. If no time be stipulated, the pledgee may give notice that he requires a prompt fulfilment of the engagement, upon non-compliance with which he may sell.

The possession of the pledge does not affect the right of the pledgee to enforce performance of the engagement, unless there be a special agreement, by which he has engaged to resort to the pledge only, or to look to it in the first instance.

Though the pledgee may sell, he cannot appropriate the pledge to himself upon the default of the pledgor; nor is he at liberty to use it without the permission of the owner, expressed or clearly implied. Such an implication arises where the article is of a nature to be benefited by or to require being used, in which latter case the use is not only justifiable but indispensable to the discharge of the duty of the pledgee. (*Commentaries on Law of Bailment*, by Storey.)

As to the power of an agent to pledge, see FACTOR.

PLEDGE (Roman). This word formerly denoted a person who was a security for another; but it now denotes a thing which is a security, and generally for a debt.

The chief rules of English law as to mortgaging and pledging are derived from the Roman law, in which however there is no distinction among pledges, dependent on the nature of the thing pledged, whether it was a thing moveable or immoveable, corporeal or incorporeal; and a thing could not be the subject of pledge unless it could be the subject of buying and selling, for the power of selling a pledge was an important part of the creditor's security. A man might pledge a thing either for his own or another person's debt. The terms used in the Roman law to express pledging, and also the thing pledged, are Pignus and Hypotheca. It is properly hypotheca, where there is a bare agreement (nuda conventio) that a thing shall be a security to a creditor for a debt, and the thing remains in the possession of the debtor. The word hypotheca (ὑποθήκη) is Greek, and denotes a thing subjected to a claim or demand. When the thing was delivered to the creditor, it was called Pignus (Isid., *Orig.*, v., c. 25); and as moveable things would for obvious reasons be most frequently delivered, a notion got established among some Roman lawyers, aided by an absurd etymology (pignus appellatum à pugno, *Dig.*, 50, tit. 16, s. 238), that the term pignus was applicable only to a pledge of moveable things; and this notion has also prevailed in modern times. (Ryall *v.* Rowles, 1 Vez.) The true etymology of pignus seems to be the same as that of pactum. It is generally said that hypotheca corresponds to the English mortgage, and pignus to pawn or pledge; but this is not the case. No ownership was transferred by the Roman hypotheca. The term hypothecation in English law is still used to express the mortgage of a ship or its cargo.

Originally, when a man wished to borrow money on the security of a thing, he transferred the ownership of the thing to the lender by mancipatio, or in jure cessio, sub lege remancipationis, or sub fiducia; and the borrower could recover his ownership by usureceptio (Gaius, ii. 59, &c.) when the debt was paid, and in some other cases also. But this mode of giving security was found to be disadvantageous to the debtor, and subsequently the thing was merely put into the hands of the creditor with a power of sale in case the debt was not paid according to the agreement; but this gave the creditor no ownership, and consequently he had no actio in rem against any third person, and therefore no sufficient security for his debt. The prætor's edict found a remedy for this by giving to the creditor a real action, called serviana actio, against any person who was in possession of the thing pledged, for the purpose of recovering it; and the extension of this right of action, under the name of the quasi-serviana actio, also called hypothecaria, gave to the hypotheca the full character of the pignus.

Thus the Roman law recognised the pignus, which arose from the contractus pignoris, and the hypotheca, which arose from the pactum hypothecæ. But there were other cases which in the Roman law were considered cases of pignus.

The pignus praetorium arose when a creditor, by a judicial decree, was allowed to enter into possession (mittebatur in possessionem) either of the whole property of a debtor or any part of it; but there was no pignus till the creditor took possession. It has been conjectured that this kind of pignus owes its origin to the old pignoris capio. (Gaius, iv. 26, &c.)

There was also the tacit hypotheca, which was founded on certain acts. In the case of prædia rustica, the fruits of the ground were a pignus to the owner for the rent, even if there was no agreement to that effect; and if a man lent money for the repairs of a house, the building became a pignus for the debt.

The creditor, though in possession of the pledge, could not use it or take the profits of it without a contract to that effect, which was called antechresis, or mutual use. If he took the profits, he had to render an account of them when his debtor came to a settlement with him; but he was entitled to an allowance for all necessary expenses laid out on the thing pledged, as, for instance, for the repairs of a house.

After the time agreed on for payment was passed, the creditor had the right of selling the pledge and of retaining his debt out of the produce of the sale. If the produce of the sale was not sufficient to discharge the debt, he had a personal action against the debtor for the remainder. Originally perhaps he could only have this right of sale by express contract, but subsequently the right to sell (jus distrahendi sive vendendi) was an essential part of the contract of pledge. Though the creditor was not the owner of the thing (dominus), still he could transfer ownership to the purchaser, a doctrine that is only intelligible on the supposition that he sold it as the attorney or agent of the debtor. But the creditor could only sell the thing in respect of the debt for which the thing was pledged, and not in respect of other debts due to him from the debtor, though he might apparently retain the surplus of the sale in his hands as a satisfaction for such other debts. The power of sale was to be exercised pursuant to the terms of the contract; and when there was no agreement as to the form and manner of sale, the law prescribed the mode of proceeding, which the creditor was bound to observe strictly. It was once usual to insert in the contract of pledge a Lex Commissoria, that is, a condition by virtue of which the thing pledged became the absolute property of the creditor, if the money was not paid at the time agreed on. But by a constitution of Constantine (*Cod.*, viii., tit. 35) it was forbidden to insert such a clause in the contract. If anything remained over after satisfying the creditor, it belonged to the debtor.

A thing might be pledged to several persons in succession, whose claims were to be satisfied according to their priority in time. But there were some exceptions to this rule introduced by special laws, which gave a preference to certain persons and claims, independent of the order of time; and a constitution of Leo gave a priority to a pledge which was contracted by a public instrument (instrumentum publice confectum), or by a private instrument attested by three witnesses, over every other pledge which was to be proved by any other evidence. This law was intended to prevent fraudulent agreements by which a pledge would be antedated.

Where there were several creditors, he who had the priority over all was entitled to sell and pay himself; the surplus, if any, belonged to the creditor who was next in order, and so on till the whole was exhausted. If a creditor who was posterior in order of time, wished to stand in the place of him who had the priority, he could do so by paying him his debt, and he then occupied (successit) the same place and had the same right as the prior creditor. This doctrine was founded on the assignable character of a pledge, for though the pledgee was not the owner of the thing, and could only sell it in the manner already mentioned, he could transfer his interest to an assignee, and could even transfer to a second pledger the jus vendendi when the second pledger was excluded from such right by special contract. (*Dig.*, 20, tit. 3, s. 3.) When a subsequent creditor advanced a sum of money which was applied to the preservation of the thing pledged, for instance, for the purpose of repairing a ship, he had a priority over creditors of earlier date, on the ground of his having by his loan secured the thing. (*Dig.*, 20, tit. 4, s. 5.) The same rule, perhaps somewhat more limited, prevails in our own law as to money lent on the security of a ship.

As the pledger remained the owner of the thing pledged, he could of course sell it, but the purchaser took it subject to the pledge. The creditor who was in possession of a pledge was answerable for any damage that befel it owing to dolus or culpa, that is, fraud or neglect, but he was not answerable for unavoidable loss.

A pledge was determined in various ways; by the destruction of the thing, by the creditor releasing the debtor, by the debtor paying the debt, and in other ways. When the debtor offered the money to his creditor, he was entitled to have the pledge restored to him. This might be obtained by an actio pignoraticia, which was an actio in personam, and also lay for damages done to or sustained by the thing, or for the surplus of the money if the pledge had been sold by the creditor. The creditor had a contraria pignoraticia actio against the debtor for expenses incurred as to the pledge, for any fraud in the matter of the pledge, as passing off base for better metal, and in some other cases.

The Roman law of pledges has been treated by various writers at great length. A compendious view of it is contained in Brinkmann's 'Institutiones Juris Romani,' Slesvici, 1822; in Marezoll, 'Lehrbuch der Instit. des Röm. Rechtes,' Leipzig, 1839; and in Ayliffe's 'Law of Pledges or Pawns,' London, 1732; see also 'Dig.,' 20, tit. 1, &c.; 13, tit. 7; 'Instit.,' iv., tit. 6; 'Cod.,' 8, tit. 14, &c.

PLEDGING, CUSTOM OF, derived from the French *pleige*, a surety or gage. The expression 'I'll pledge you,' in drinking, is deduced by some of our writers on popular antiquities from the times when the Danes were in possession of England. It is said to have been the custom of that people to seize the moment when a native of the island was in the act of drinking, to stab him with a knife or dagger; whence people could not drink in company unless some one present would be their pledge or surety that they should receive no harm. (Brompton; Sir Richard Baker's *Chron.*, edit. 1670, p. 316; Henry, *Hist. Great Brit.*, 4to., vol. ii., p. 539: see also Eric Pontoppidan's *Gesta et Vestigia Danorum extra Daniam*, vol. ii., p. 209.)

Others state the custom to have taken rise from the death of King Edward the Martyr, son to Edgar, who, by the contrivance of his step-mother Elfrida, was stabbed in the back as he was drinking.

Brand thought the expression meant no more than that if you took your cup or glass, I *pledged myself to you* that I would follow your example. (Brand's *Popular Antiquities*, vol. ii., pp. 223-232.)

PLEI'ADES. [TAURUS.]

PLEIOCENE, or PLIOCENE. By this title (derived from *πλεῖον*, *more*, and *καινός*, *new*) Mr. Lyell wishes to characterise the upper part of the tertiary strata. There are in his view older and newer Pleiocene formations, and some have used for the latter class the expression Pleistocene, or *most* new.

PLEI'ODON, Conrad's name for the genus *Iridina* of Lamarck. [NAIADES.]

PLEI'ONE, Savigny's name for a genus of *Dorsibranchiata* (*Amphinome*, Bl.), which, with the same tentacles as *Chloeia*, Sav., have branchiæ in the form of tufts.

Locality.—The Indian Seas, where some of them grow to a large size.

Example, *Pleione caruncula*ta (*Terebella carunculata*, Gm.)

PLEKOCHE'ILUS, the Rev. Lansdown Guilding's name for a genus of *Pupadæ* (Guild.), *Bulimus* of authors.

Generic Character.—*Animal* hermaphrodite. Body corrugate, heliciform; *head* bilobate; *tentacles* four, the two longer ones with oculiferous terminations; *mandible* very lunate, the ossicula transverse, the triangular appendage cutaneous. *Intromittent organ* retractile, at the root of the right greater tentacle. *Mantle* perforated by a common foramen. *Ova* few, large, with a calcareous shell or crust.

Shell barely umbilicate, dextral, oval, spiral; the spire elevated, but obtuse, the two last whorls largest, ventricose. *Aperture* entire, elongated. *Columella* with a single plait, which is cavernoso-inflex. *Lip* thickened, marginate. (Guild.)

Example, *Plekocheilus undulatus*.

Description.—Body olivaceous-black, foot pallid beneath; tentacles white at the apex; eyes black.

Shell stout, turgid, plaited longitudinally, indistinctly striated transversely, ferruginous chestnut, with oblique brown undulated bands; whorls five.

Eggs oval-elliptic, indistinctly corroded, numerous, large, glutinously deposited in a heap, and joined by a gelatinous thread; at first yellowish, shining, afterwards (when dry) pearly-calcareous.

Young pallid, the shell diaphanous, prettily corroded, and of a silky lustre, no striæ, and the lips simple. The *adolescent shell* subdiaphanous, the bands more distinct. The *old shell* covered with a glaucous-brown, thick wrinkled epidermis, the bands evanescent, often deeply corroded. (Guild.)

Mr. Guilding states that this fine species occurs in immense numbers in the forests of the island of St. Vincent, generally withdrawn, but sometimes even copulating in the day-time. The ova are agglutinated to the vaginating leaves of the *Tillandsiæ*, which, from holding water, secure a damp atmosphere at all times. The lately excluded shell long stood in Mr. Guilding's cabinet as a nondescript *Succinea?* with a depressed spire. He at last traced it *ab ovo*, and from the examination of this and the young shell of *Bulinulus undulatus*, he cautions the zoologist against hastily separating such small shells as do not bear on the lip some positive mark of maturity. In the young *Plekocheili*, he observes, the whole shell is without striæ, and is beautifully corroded on its surface, the plicæ being smooth and distinctly marked as they are added by the first operations of the mantle. In the young of the other snail, he observes, are seen numerous fine longitudinal and transverse striæ, which it will be in vain to look for in the parts added by the animal as it advances in strength, a circumstance that would have led to the multiplication of species, had not specimens been discovered in various stages (*Zool. Journ.*, vol. iii.)

PLENIPOTENTIARY. [AMBASSADOR.]

PLEODONTS, the name assigned by MM. Duméril and Bibron to their first subfamily of *Lézards Lacertiens* (Lacertian Lizards), or *Sauriens Autosaures* (Autosaurian Saurians).

The *Pleodonts* are divided into two great groups: the first with a compressed tail, surmounted with crests, as in the *Crocodiles;* the other with the tail perfectly conical, or very slightly flattened on its four surfaces, so that it still appears rounded. MM. Duméril and Bibron have employed the expression *Cyclotetragonal* to designate this mixed form.

In the subfamily of the Pleodonts these distinguished zoologists have placed the species whose teeth are completely solid, being without any internal cavity, and very firmly fixed by their edges and their external surface to the jawbones, in a groove hollowed out along their internal border, against which the teeth, especially the anterior ones, are so applied, that their point or free extremity seems to be always a little directed outwards.

In the first group of the *Pleodonts*, or *Lacertians with compressed tails* (*Cathétures*), three genera only are comprised—1. *Crocodilurus* (*Dragonne*, part, Cuvier; *Ada*, part, Gray). 2. *Thorictes*, Wagl. (*Dracæna*, Daud.; *Ada*, part, Gray). 3. *Neusticurus*, Dum. and Bib.

In the second group of *Pleodonts*, those with compressed tails (*Conicaudes*, or *Strongylures*), the following genera are included:—1. *Aporomera*, Dum. and Bib. 2. *Salvator*, Dum. and Bib. (*Tupinambis*, Daud., part, the *Sauvegardes*, or *Monitors*, Cuv.; *Tejus*, Merrem, part; *Custa*, Fleming; *Monitor*, Fitzing.; *Podinema* and *Ctenodon*, Wagl., Wiegm.; *Exypneustes*, Kaup.; *Podinema*, C. Bonap.; *Tejus* (subgenus *Teguixin*, Gray). 3. *Ameiva* (*Ameiva*, Cuv., part, Fitzing.; *Tejus*, part, Merrem; *Cnemidophorus*, part, Wiegm., Bonap.; *Tejus* (subdiv. *Ameiva*, part, Gray). 4. *Cnemidophorus*, Wagl. (*Ameiva*, part, Cuv., Fitzing., Gray; *Cnemidophorus*, part, Wagl., Wiegm.). 5. *Dicrodon*, Dum. and Bib. 6. *Acrantus*, Wagl. (*Tejus*, part, Merrem; *Tejus*, Fitzing.; *Acrantus*, Wagl., Wiegm.). 7. *Centropyx*, Spix (*Trachygaster*, Wagl.; *Pseudo-Ameiva*, Fitzing.).

PLESIOSA'URUS, the Rev. W. D. Conybeare's name for an extinct genus of an extinct family, the *Enaliosaurians*, and first described by him, with the assistance of Mr. De la Beche, in the *Transactions of the Geological Society of London*, in 1821.[*] A restoration of the skeleton, together with that of *Ichthyosaurus*, was given by Mr. Conybeare in a subsequent volume of the same *Transactions*[†] (1824), from an almost perfect specimen of *Plesiosaurus dolichodeirus*, and the accuracy of this restoration is still universally acknowledged. This genus is the *Halidracon* of Wagler.

Since the article Ichthyosaurus was written, Professor Owen has made that part of his *Report on British Fossil Reptiles* which relates to the *Enaliosauria*, or 'Lizards of the Sea,' to the *British Association for the Advancement of Science*. This paper, which adds another to the many instances already before the public of the Professor's diligent research and acute observation, has brought the history of the *Ichthyosauri* and *Plesiosauri* down to the present day, throwing light upon many points which required elucidation, and completing the catalogue of the species of both genera, after he had visited the museums of this country and of the Continent.

Professor Owen characterises the *Enaliosaurians* as vertebrate, air-breathing, and cold-blooded animals; referrible therefore to the great class of *Reptilia* in the Cuvierian system, and indicative of a primary modification of the typical structure of that class, by which the Enaliosaurs were fitted more especially for a marine life. The proof that these animals respired atmospheric air immediately, is, he observes, afforded by the position and structure of the nasal passages, and by the osseous mechanism of the thoracic-abdominal cavity, whilst the evidence that they were cold-blooded animals reposes on the unanchylosed condition of the elementary osseous pieces of the occiput and other cranial bones, of the lower jaw, and of the vertebral column: the laws of organic coexistence justify the conclusions, to which the Professor comes from these conditions of the osseous system, that the heart was adapted to transmit only a part of the circulating blood through the respiratory organs. He then shows that the peculiar modifications of the Saurian type, or the special Enaliosaurian characteristics, consist in the absence of the ball and socket articulations of the bodies of the vertebræ,—the position of the nostrils at or near the summit of the head; their separated hæmapophyses;[*] the numerous short and flat digital bones, which must have been enveloped in a simple undivided tegumentary sheath, forming in both the fore and hind extremities a fin resembling in external appearance the paddles of the *Cetacea*. Although other genera of fossil saurians were aquatic and marine, and consequently possessed extremities modified for swimming, as are those of the marine *Chelonians* of the present day, and, in a less striking degree, the feet of the *Crocodiles* among existing saurians, those reptiles only ought, in the opinion of Professor Owen, to be regarded as true Enaliosaurs, which combine limbs fitted for swimming with the cranial and vertebral characters above defined.

The characters of the genera *Plesiosaurus* and *Ichthyosaurus*, the types of the two principal modifications of anatomical structure offered by the Enaliosaurians, are mainly derived from modifications of the vertebral column, as well with regard to the form and configuration of the individual bones, as to the relative groups of the cervical, dorsal, and caudal vertebræ. Professor Owen has also found that the vertebræ afford the best characters for the distinction of species as well as of genera.

The most conspicuous and remarkable character of the vertebræ in *Plesiosaurus* is the extraordinary length of the cervical portion, including from twenty to forty vertebræ. The articular surfaces of their bodies are either flat or slightly convex in the centre, and most frequently concave at the periphery. Two pits are generally presented at the under part of the bodies, but this character is not constant. The cervical vertebræ of the *Plesiosauri* generally present the centrum, the neurapophyses, and the ribs in a separate or unanchylosed state, and although in general no transverse processes are developed in this region, an analogy with the structure characteristic of this part of the spine in the Crocodile is maintained in the division of the articular surface for the cervical rib into an upper and lower portion by a horizontal fissure—a structure which, Mr. Owen observes, is well described and figured by Conybeare in the

---

[*] *Geol. Trans.*, vol. v., p. 556, 1st series.

[†] Vol. i., pl. xlix., 2nd series.

[*] Professor Owen divides the parts or processes of a vertebra into *autogenous* or those parts which are independently developed in separate cartilages, and *exogenous*, or those which shoot out as continuations from these independent constituents.

Autogenous, or true Elements. 1, The *centrum* or body of the vertebra, which, in *Mammalia*, is complicated by two epiphyses. 2, Two superior laminæ developed to protect the great nervous cord, which rests on the upper surface of the *centrum*, and which he has therefore proposed to call *neurapophyses* (*periaux* or *perivertebral* elements of Geoffroy St Hilaire). 3, Two inferior laminæ developed generally to protect the great blood-vessels on the under surface of the centrum, and which he has proposed to call *hæmapophyses* (Chevron bones of Conybeare, *paraaux* or *paravertebral* elements of Geoffroy St. Hilaire—the reasons for not adopting which terms are given by the Professor). 4. The superior process (*epiaux* or *epivertebral* elements of Geoffroy), which is connected and generally anchylosed with the distal extremities of the *neurapophyses*, and forms, in conjunction with those processes, the superior arch of the vertebra. 5, An inferior spinous process, which is connected and commonly anchylosed with the distal extremities of the *hæmapophyses*, forming, in conjunction with these, a chevron or V-shaped bone. To the category of *autogenous* vertebral pieces, he holds that the *ribs*, which generally are anchylosed to the other vertebral elements in the cervical, sacral, and caudal vertebræ of the warm-blooded vertebrate classes, belong.

Plesiosaurus dolichodeirus: as these vertebræ of the neck approach the dorsal, the inferior part of the costal articulation becomes smaller, and a corresponding increase of surface is afforded by the superior facet, which also gradually rises from the centrum to the neurapophyses, and in the dorsal vertebræ stands boldly out as a true transverse process from the upper side of the base of each neurapophysis. The transverse processes of the sacral vertebræ subside to the level of the neurapophyses; and as the caudal vertebræ recede from the trunk, the articular surface, which, as in the neck, represents or takes the place of the transverse process, gradually descends, and passes from the neurapophyses to the side of the centrum, but is not divided by the longitudinal groove which characterises the costal surface in the neck: but it must be borne in mind that this groove is more marked in some species of *Plesiosaurus* than others; and indeed Professor Owen has seen Plesiosaurian cervical vertebræ in which no trace of it was visible. 'The neurapophyses,' continues our author, 'are commonly unanchylosed with the vertebral centres in any part of the spine, and in some instances throughout the cervical, and at the anterior part of the dorsal region, the neurapophyses have appeared to be joined each by an articular surface to the spine above, as they are to the centrum below,—the spines here remaining apparently throughout life unanchylosed to the neurapophyses. This condition of the upper vertebral elements is rarely seen in any cold-blooded vertebrate animals, and never in the warm-blooded classes. In those parts of the spine where the vertebræ enjoyed less mobility upon each other than in the neck, the spines become anchylosed to the neurapophyses at an earlier period. The hæmapophyses co-exist with the ribs or paravertebral elements in the caudal region of the spine, but they continue throughout life to be unattached by bone either to the centrum above or to each other below; and here also their spine is not developed, and consequently no true chevron bone is formed in the *Plesiosauri*. The hæmapophyses are also continued along the inferior surface of a great part of the abdomen, forming there the sternal or abdominal ribs; and just as the neurapophyses are developed in the transverse direction to protect the expanded cerebral masses in the cranial region, so here the hæmapophyses are in like manner elongated transversely, and their spine is introduced and modified to form a third mesial rib-like bar, connecting however, as usual, the lower or distal extremities of the hæmapophyses, and completing the osseous cincture of the abdominal viscera. The tail in the *Plesiosauri* is relatively much shorter than in the *Ichthyosauri*, and there is an obvious reason for the curtailment of this part of the animal; for, in the *Plesiosauri*, the length and mobility of the neck renders a special development of the tail for producing the lateral movements of the head unnecessary. The bodies of the vertebræ, in most species of *Plesiosaurus*, are traversed vertically by two vascular canals, which lead from the medullary or spinal canal to the inferior surface of the centrum, where they terminate each by an orifice, and sometimes by two orifices on each side of the middle line. These orifices are not however a constant character of the genus *Plesiosaurus*, neither are they peculiar to this genus, being present in the vertebræ of the *Cetacea*, as well as in those of other *Sauria*. In a section of the vertebral centrum of a *Plesiosaurus*, the osseous texture for some lines near the anterior and posterior articular surfaces is denser than in the rest of the vertebræ, and the direction of the laminæ and fibres is vertical; in the intermediate portion the laminæ are horizontal.'

Cranium.—Though the head of the *Plesiosauri* resembles that of the crocodiles in its general form, it is, as Professor Owen observes, relatively much smaller in proportion to the body. The elongated form of the strong and prominent cranial bones, most of which extend from point to point, with wide interspaces like the timbers of a scaffolding, forms, he remarks, one of the first indications of a deviation from the crocodilian type, and of the affinity of the Plesiosaurus to the *Lacertian Sauria;* and this affinity, he adds, is further exemplified in the condition of many of the individual bones. He proceeds to state that the occipital bone includes the basilar, lateral, or ex-occipital pieces in a permanently separated condition, as in other reptiles; the basi-occipital forms a larger proportion of the articular tubercle for the atlas, and the ex-occipitals a less proportion than in the crocodiles; and the circumference of the *foramen magnum* is completed by the supra-occipital element, in both which respects the Plesiosaurus manifests its affinity with the *Lacertian Sauria.* The mastoid elements extend from the occipital to the tympanic bones; but above these, and between the occiput and the strong arched pedicle supporting the lower jaw, a vacuity leads from the occipital region to the temporal fossæ. The corresponding openings in the skull of the *crocodiles* are, he remarks, reduced to very small size in consequence of the expanded form and oblique position of the tympanic bone, but in the *Lacertian Sauria* they are as wide as they are in the *Plesiosaurus,* if not wider.

Professor Owen describes the *parietal* bone as strong and triradiate, consisting of a median piece corresponding with the normal parietal in the crocodiles, and of two transverse elongated processes, formed, as it were, by a bifurcation of the posterior part of the median piece; and in a young specimen of *Plesiosaurus Macrocephalus,* in the museum of the earl of Enniskillen, he found the median or sagittal suture dividing the two parietals still distinct; in older specimens of *Pl. Hawkinsii* he always found it obliterated; affording evidence to justify the description of the parietal bone as single and triradiate. The Professor proceeds to notice the median portion of the parietal bone as offering two modifications of structure which point out in a striking manner the deviation of the Plesiosaurus from the Crocodilian type and its approximation to the Lacertian type of the Saurian structure. The first of these is the median crest or ridge, from which the surface slopes away on each side; proving that the temporal muscles were relatively as strongly developed as in the *Iguanæ* for instance, and were only separated from each other at the top of the head by the intermuscular ridge. The ponderous jaws of the crocodiles, on the contrary, are worked principally by the masseter and pterygoid muscles, and in those Saurians the temporal muscles are small and separated by a flattened space occupying nearly the whole of the simple parietal bone. The second modification, which brings the Plesiosaurus near to the lizards, is a moderate-sized elliptical vertical perforation of the median part of the parietal bone, a few lines behind the coronal suture, analogous to the perforation in the *Iguana* described by the Rev. Lansdown Guilding as the *foramen Homianum:* there however it is placed directly upon the coronal suture, in the situation of the *anterior fontanelle;* but the Professor observes that the same foramen exists in many other genera of Lacertian Sauria; and in *Monitor, Lacerta proper,* &c. it is situated entirely in the parietal bone. In the Crocodilians there is no trace of this foramen. The third modification, which approximates the *Plesiosauri* to the Lacertian type and exhibits a difference from the Crocodilian structure, is the posterior bifurcation of the parietal bone, forming processes of considerable length and constituting the most prominent parts of the cranium; these are articulated with the tympanic bone by means of an oblique sigmoid suture. The *frontal* bone consists of a median, two anterior, and two posterior pieces. The median frontals extend as far forwards as the midspace between the small nostrils, and appear to terminate in a point between the commencement of the narrow nasal bones. The interfrontal suture of Lord Enniskillen's young *Pl. macrocephalus* is elevated by a ridge continued forwards from the parietal crest. The outer margin of the median frontal forms the superior boundary of the orbit. The anterior frontal enters into the formation of the anterior and superior angle of the orbit, and is wedged in between the mid-frontal and superior maxillary bones. The posterior frontal bounds the orbit posteriorly, and extends downwards to join the malar bone, like the columnar portion of the post-frontal bone in the crocodiles; but Professor Owen observes that it is broader and more superficially situated in the Plesiosaurus, thus bearing a greater resemblance to the corresponding part of the structure of the skull in the *Lacertian Sauria.* A further and more striking degree of difference from the Crocodilian type is manifested in the posterior frontal, for it is not extended backwards to join the mastoid, so that the skull of the Plesiosaurus does not present an osseous ridge traversing longitudinally the temporal fossa, like a second zygoma, and dividing it into an upper and lower cavity, as in the Crocodiles. The *Zygomatic* element of the *temporal* bone, instead of being extended obliquely parallel with the tympanic bone and joined to it, stretches horizontally from the malar and post-frontal bone backwards to the lower end of the tympanic, and, as in the Lacertian Saurians, becomes at tached by its two extremities only. In its general form, and especially in its length, the tympanic bone is intermediate between the Crocodilian and Lacertian types, exceeding them both however in robustness. In the *facial* bones the resemblance to the Lacertian Saurians begins to diminish, and the approximation to the Crocodiles to increase; and this tendency is further shown in the strength of the whole maxillary apparatus, the great relative size of the intermaxillary bones, the rugged exterior surface of the osseous parts, and particularly in the distinct alveolar cavities of the teeth: but a striking exception to this tendency is manifested in the external nostrils; their size and position, combined with the structure of the paddles, point out the analogy of the extinct Enaliosaurs to the existing Cetaceans, offering, as the Professor observes, a beautiful example of the adaptation of structure to the peculiar exigencies of a species. The respiratory apertures are situated a little before the orbits near the highest part of the head: in the Crocodiles they are placed near the anterior extremity of the snout, blended together into a single aperture, and having nearly the whole of their circumference formed by the intermaxillary bones, which, in *Plesiosaurus*, make an extremely small part of the boundary of the nasal apertures, which last chiefly consist on each side of an interspace at the convergence of the anterior frontal, nasal, and superior maxillary bones, and are separated from each other by the nasal bones, as in the *Lacertian Sauria.* The intermaxillary suture extends from the anterior part of the nostrils forwards to a little more than half way between the orbit and the anterior extremity of the cranium. One of the strongest of the inferior teeth usually rises just in front of this suture, and there a slight notch seems, the Professor observes, to correspond with that tooth, presenting a resemblance to a very characteristic structure in the true Crocodiles. The lachrymal bone forms a great proportion of the anterior part of the orbit, and the superior maxillary enters next into the formation of the circumference of the orbit below the lachrymal bone: the malar bone rests upon its posterior extremity by an oblique suture. The posterior margin of the malar bone is joined to the posterior frontal bone as well as to the zygomatic, thus completing the osseous boundary of the orbit posteriorly. The usual complicated structure observable in the Saurians appears in the *lower jaw* of the *Plesiosaurus.* The dentary piece presents evidence of its soon becoming anchylosed to its fellow at the symphysis: it is chiefly remarkable for the expansion of its anterior extremity. No intervening vacuity separates the angular and surangular pieces as in the Crocodiles, but those pieces are joined together throughout, as in the Lacertian group. The surangular piece rises higher and forms a sharper edge for the insertion of the temporal muscles than in the Crocodiles, a structure which agrees with the greater development of these muscles, as indicated by the size of the temporal fossæ. 'The articular piece presents a regular and deep concavity for the reception of the articular end of the tympanic bone: it is, as Mr. Conybeare has well remarked, more developed than in the Crocodile, and thus approximates more nearly to the corresponding part in the Lacertian type. The angular piece is prolonged backwards beyond the joint, but not quite to the same extent as in the Crocodiles.'

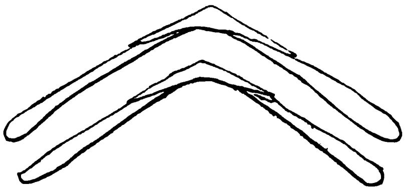
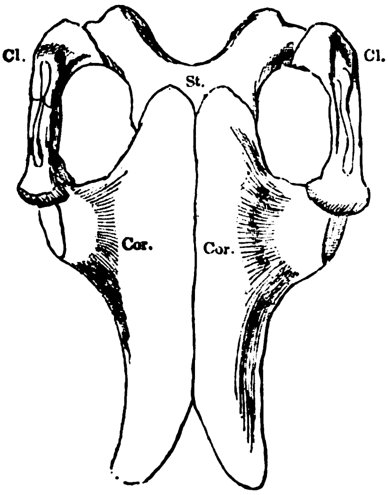
Professor Owen next proceeds to describe the *sterno-costal arcs*, observing that the ordinary or vertebral ribs have been already spoken of as essential parts or appendages of a vertebra. The free extremities of the ribs are connected together, in the abdominal region, by the series of intermediate, slender, elongated pieces, to which Conybeare gave the appropriate designation which has just been noticed. Each of these sterno-costal arcs includes, in the Plesiosaurus, seven pieces. The median piece is transversely elongated, slightly bent, and pointed at both extremities; the lateral pieces are similarly formed, except that the extremity of the outermost, which joins the vertebral rib, is obtuse: each piece, continues Professor Owen, as it recedes from the median line, overlaps the anterior part of the rib which it succeeds, where it is adapted to an oblique groove. This kind of joint, observes the Professor, probably admitted of a yielding or sliding motion of the pieces one upon the other, and favoured, as Dr. Buckland has remarked, considerable expansion of the cavity containing the lungs.



Sterno-costal arcs of Plesiosaurus. (Conybeare.)

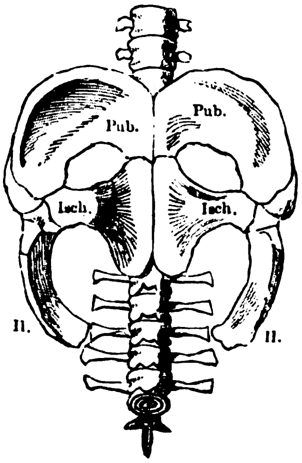
Pectoral arch. The broad coracoid bones, remarkably expanded as they are in the antero-posterior direction, are noticed by Professor Owen as the most conspicuous of those composing the pectoral arch: he describes their internal and anterior margins as gently convex, and meeting at the mesial plane, where they overlap the anterior thoracic ribs. Into their anterior interspace is wedged the ento-sternal piece, consisting of a short mesial process and two broad lateral expansions. A strong triradiate bone, which, in Mr. Owen's opinion, seems to represent, as in the Chelonians, the scapula and clavicle united, is arched from the outer extremity of the coracoid bones, with which it combines to form the shoulder-joint, near which last point it sends upwards and obliquely backwards, a branch or process representing the true scapula



Humero-sternal part of Plesiosaurus. (Conybeare.)
St., sternum; Cl., clavicle; Cor., coracoids.

Pectoral extremity. The *humerus* is described as a stout and moderately long bone, curved slightly backwards, rounded at its proximal extremity, and flattened as it approaches the elbow joint. The *radius* and *ulna* are both short and flat bones, but relatively longer and more distinctly marked than in *Ichthyosaurus*; the *radius* is nearly straight; the *ulna* curved, its concavity being directed towards the radius. The distinctly defined *carpus* consists of a double row of small flat rounded *ossicula*, in number from six to eight. The *metacarpal* bones are elongated, slender, flattened, and slightly bent. The fingers, or 'digits,' as they are termed by Mr. Owen, never exceed the number of the metacarpal bones, but generally consist of more than the usual number of phalanges. The first or radial digit, which corresponds with the thumb, has generally three phalanges, the second six or seven, the third eight or nine, the fourth eight, and the fifth six phalanges. These bones, the Professor observes, are moderately long and slender, but gradually taper towards the distal end of the digits; and they are joined together in each digit by flattened surfaces, indicative of a mere yielding movement on one another; he has little doubt that they were enveloped, like the paddles of the *Cetacea*, in a common sheath of integument.

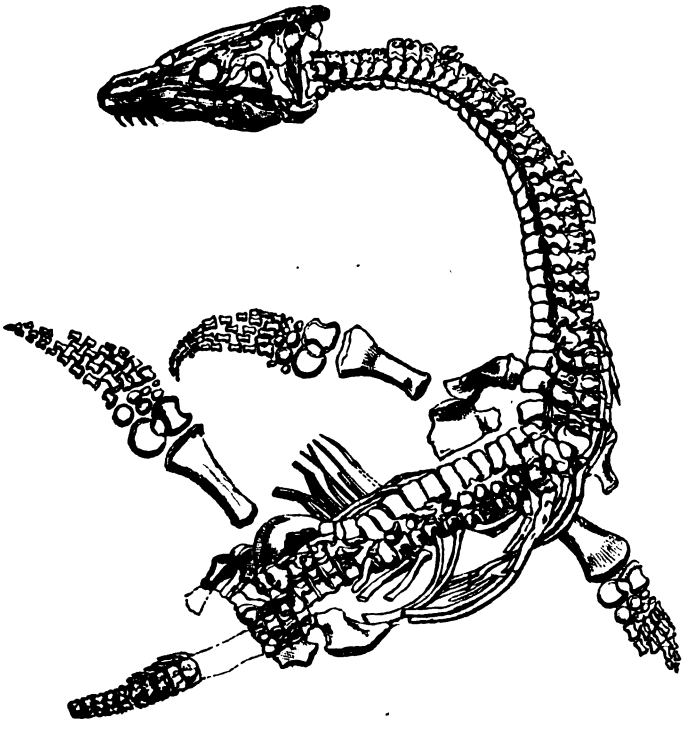
Pelvic arch. The hinder or pelvic extremities are described as almost always equal, sometimes, as in *Pl. macrocephalus*, exceeding the anterior ones in size, and the pelvic arch as consisting of a strong and short *ilium*, and a broad *pubis* and *ischium*, both of which are expanded in the antero-posterior direction analogously to the coracoid bones in the pectoral arch.



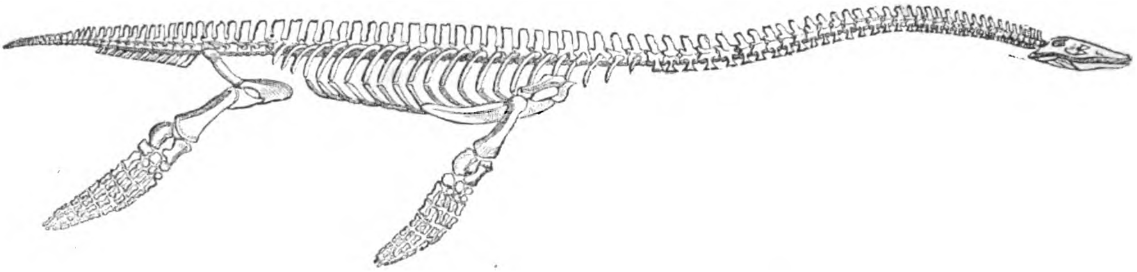
Pelvis of Plesiosaurus. (Conybeare.)
Pub., pubis; Isch., ischium; Il., ilium.

Pelvic extremity. Professor Owen remarks that the radiated appendages of the pelvic arch so closely correspond with those of the pectoral arch, as to require little notice. In the modifications of the two bones of the leg, he found that the posterior bone, or *fibula*, corresponds in its curved form with the *ulna*, illustrating an analogy manifested in other animals. The *tarsal* bones are principally remarkable for their small size on the tibial or anterior side of the series, indicating that the hind paddle had a freer inflection forwards, or upon the *tibia*, than in the opposite direction. This structure, the Professor observes, may have given a compound motion to the propelling stroke of the paddle, similar to that which in skilful rowing is called 'feathering' the oar.

The five *metatarsals* and their digits are found to correspond in structure with those of the fore paddle. The first



Plesiosaurus macrocephalus. (Buckland; Owen.)



Skeleton of Plesiosaurus dolichodeirus restored. (Conybeare principally.)

or tibial metatarsal supports three phalanges, the second five, the third eight or nine, the fourth eight, and the fifth six. The articulating extremities of the phalanges of both the fore and hind paddles are, Mr. Owen observes, subconcave, with an irregular surface, indicating that they were joined by ligaments or fibro-cartilage, and not by synovial membrane.

For the particular variations in the skeletons of the different species we must refer to the able memoir from which the above general description of the osseous parts is taken.

The following species, sixteen in number, are recorded by Professor Owen :—*Plesiosauri Hawkinsii*, Owen ; *dolichodeirus*, Conybeare ; *macrocephalus*, Conybeare ; *brachycephalus*, Owen ; *macromus*, Owen ; *pachyomus*, Owen ; *arcuatus*, Owen ; *subtrigonus*, Owen ; *trigonus*, Cuv. ; *brachyspondylus*, Owen ; *costatus*, Owen ; *dœdicomus*, Owen ; *rugosus*, Owen ; *grandis*, Owen ; *trochanterius*, Owen ; and *affinis*, Owen.

Habits of Plesiosaurus.—We now proceed to examine the structure of this extraordinary animal. Dr. Buckland truly observes that the discovery of this genus forms one of the most important additions that geology has made to comparative anatomy. 'It is of the Plesiosaurus,' says that graphic author, in his 'Bridgewater Treatise,' 'that Cuvier asserts the structure to have been the most heteroclite, and its characters altogether the most monstrous that have been yet found amid the ruins of a former world. To the head of a lizard it united the teeth of a crocodile ; a neck of enormous length, resembling the body of a serpent ; a trunk and tail having the proportions of an ordinary quadruped, the ribs of a cameleon, and the paddles of a whale. Such are the strange combinations of form and structure in the *Plesiosaurus*,—a genus, the remains of which, after interment for thousands of years amidst the wreck of millions of extinct inhabitants of the antient earth, are at length recalled to light by the researches of the geologist, and submitted to our examination in nearly as perfect a state as the bones of species that are now existing upon the earth.' Conybeare thus speaks of the supposed habits of this extinct form, which he had in a manner built up before our eyes, when materials were very scanty compared to those which have since been discovered:—'That it was aquatic is evident from the form of its paddles ; that it was marine is almost equally so, from the remains with which it is universally associated ; that it may have occasionally visited the shore, the resemblance of its extremities to those of the turtle may lead us to conjecture ; its motion however must have been very awkward on land ; its long neck must have impeded its progress through the water, presenting a striking contrast to the organization which so admirably fits the Ichthyosaurus to cut through the waves. May it not therefore be concluded (since, in addition to these circumstances, its respiration must have required frequent access of air) that it swam upon or near the surface, arching back its long neck like the swan, and occasionally darting it down at the fish which happened to float within its reach? It may perhaps have lurked in shoal water along the coast, concealed among the sea-weed, and, raising its nostrils to the surface from a considerable depth, may have found a secure retreat from the assaults of dangerous enemies ; while the length and flexibility of its neck may have compensated for the want of strength in its jaws, and its incapacity for swift motion through the water, by the suddenness and agility of the attack which they enabled it to make on every animal fitted for its prey which came within its reach.' (*Geol. Trans.*, vol. i., part 2, p. 388, N. S.)

Of the general characters of the *Ichthyosauri* Professor Owen treats as follows :—

'The Enaliosaurians of the present family differ from those of the preceding most remarkably in the shortness of the neck and the equality of the width of the occiput with that of the thorax, which almost immediately succeeds it, impressing the observer with the conviction that the recent animal must have resembled a cetacean or a fish in the total absence of any cervical constriction.

'This close approximation in the *Ichthyosauri* to the form of the most strictly aquatic animals of the existing creation is accompanied by an important modification of the articular surfaces of the vertebral centres, each of which surfaces presents a well marked concavity, leading to the inference that they were originally connected together by an elastic capsule, filled with a fluid, as in the vertebral joints of the back-bone of fishes, and the Perennibranchiate or most fish-like of the *Reptilia*.

'The structure of the fins of many species of *Ichthyosaurus* deviates from that of the cetacean paddles, and approaches in certain peculiarities more closely to that of the fins of fishes than has yet been found in any other reptile. First, the digits exceed the typical number *five*, and resemble in their numerous and small constituent phalanges the jointed rays which support the natatory membrane of the pectoral and ventral fins of true fishes ; and, secondly, numerous cartilaginous bifurcate rays were added to the bony apparatus which supports the tegumentary expansion.

'With these important modifications of the head, trunk, and extremities in immediate relation to aquatic progression, the law of the correlations of organic structure would lead us to anticipate some corresponding modification of the tail. Accordingly we find the vertebræ of this part to be much more numerous than in the previously-described Enaliosaurian group. There is no trace however of any confluence of the terminal caudal vertebræ, or of any modification of their elongated neur-apophysial and hæm-apophysial spines, such as form the characteristic structure supporting the tail of the osseous fishes. The numerous caudal vertebræ gradually decrease in size to the end of the tail, where they assume a compressed form ; and thus the tail, instead of being short and broad, as in fishes, is lengthened out, as in the crocodiles.

'The very frequent occurrence of a fracture of the tail about one-fourth of the way from its distal extremity, had led me to suspect it to be in some way connected with the presence of a tegumentary caudal fin ; and the laterally compressed form of the terminal vertebræ, since ascertained by Sir Philip Grey Egerton, has almost demonstrated the existence of such a fin.[*] The only evidence in fact which the skeleton of the cetaceous mammal affords of the powerful horizontal caudal fin which characterises the recent animal is the depressed or horizontally flattened form of the terminal vertebræ. We may infer therefore, from the corresponding vertebræ of the *Ichthyosaurus* being flattened in the vertical direction, or from side to side, that it possessed a caudal tegumentary fin expanded in the vertical direction ; and it would be highly advisable to examine narrowly the lias matrix in which the tail of the Ichthyosaur may have been imbedded for traces of carbonaceous discoloration, or of an impression of this fin, from which some idea might be formed of its shape and size.[†]

---

[*] See Professor Owen's paper 'On the Dislocation of the Tail at a certain point observable in the Skeleton of many Ichthyosauri,' *Geol. Trans.*, vol. v., p. 511, second series, just published (July, 1940); and see the article ICHTHYOSAURUS, vol. xii., p. 432.

[†] 'I would more particularly recommend this observation to be made on specimens of *Ichthyosaurus* from the lias of Barrow-on-Soar, which appears to have been more favourable for the preservation of the soft integument than in other localities. The specimen from which Dr. Buckland described the tegument of the abdomen, and that in which the tegument of the fin and the soft rays were described by me, were both from Barrow-on-Soar.' (Owen.)

'Thus, in the construction of the principal natatory organ of the *Ichthyosaurus* we may trace, as in other parts of its structure, a combination of Mammalian, Saurian, and Ichthyic peculiarities. In its great length and its gradual diminution we perceive the Saurian character; its tegumentary nature, unsupported by osseous rays, bespeaks its affinity to the Cetaceans; while its vertical position brings it close to the peculiar condition of the natatory organ in the fish.

'But it may be argued, the horizontality of the caudal fin of the *Cetacea* is essentially connected with their exigencies as breathers of the atmospheric air: without this means of displacing a mass of water in the vertical direction, the head of the whale could not have been brought with the required rapidity and facility to the surface to inspire; and as the *Ichthyosaurus* was also an air-breather, a like position of the caudal fin might be considered to be equally essential to its existence in the water.

'To this objection it may be replied that the *Ichthyosaurus*, not being warm-blooded, would not require to bring its head to the surface so frequently, or perhaps so rapidly, as the Cetacean; and moreover a compensation for the absence of a horizontal terminal fin is provided in the presence of the two posterior extremities, which are modified as paddles, and which are wholly deficient in the *Cetacea*.

'Thus I conceive that the living Ichthyosaurus must have presented the general external figure of a huge predatory abdominal fish, with a longer tail and smaller caudal fin than usual; scaleless moreover, and covered, according to the minute and careful observations of Dr. Buckland, with a smooth or finely-wrinkled skin analogous to that of the *Cetacea*.

'A closer inspection of the enduring parts of these singular inhabitants of the antient deep shows that under their fish-like exterior was concealed an organization which, in the main, is a modification of the Saurian type.'

Professor Owen, after observing that the general form of the cranium resembles that of the dolphin, but differs from it in the comparatively feeble development of the cerebral cavity, and still more essentially in the unanchylosed state of the composite cranial bones, enters into a most careful and detailed description of the skeleton, which our limits will not permit us to follow throughout, but every word of which should be attentively perused by the physiologist. We cannot however refrain from laying before the reader his description of the *pectoral arch* and the adaptation of this part of the organization, in particular, to the wants of the animal.

'We have already remarked,' says the Professor, 'that the extremities bear a resemblance, in their bony structure, to the paddles of the *Cetacea*. But this resemblance is limited to the radiated system of bones, i.e. to the *brachium, antibrachium,* and *manus*. The mode in which the locomotive member is connected with the trunk is entirely different in the two aquatic tribes. In the *Cetacea* the pectoral fin is attached to a simple scapula with a rudimental acromial and coracoid process, and is merely suspended in the flesh. In the *Ichthyosaurus*, as in the *Plesiosaurus*, the pectoral fin is connected with, and must have acted upon, a powerful and resisting osseous arch, having the sternum for its keystone. The sternum in fact here exists solely for the function of the anterior members, and does not enter at all into the formation of the costal arches or the respiratory cavity. In the *Cetacea*, on the contrary, the sternum is limited to its connection with the ribs, and to the completion of the thoracic cavity.

'In the *Ichthyosaurus* the representative of the sternum is analogous to the episternal element as it exists in the *Ornithorhynchus* and Lacertian *Sauria*, and, as in many of the latter tribe, it presents a triradiate form. One branch occupies the median line of the pectoral arch, is broad and flat, and rounded posteriorly; the other two rays branch off from each of the anterior angles of the median piece, and, diverging laterally, follow the curvature of the superimposed clavicles, to the posterior and middle part of which they are closely attached: as they proceed outwards these lateral rays of the *episternal* bone gradually diminish to a point.

'The scapula is a short but stout and broad bone, presenting the simple parallelogramical form which characterises it in the *Oviparous Vertebrata*. The anterior margin is fixed to the clavicle and to the extremity of the lateral process of the episternum· the inferior extremity presents two facets, one of which is attached to the coracoid bone, the other forms part of the articular surface for the humerus.

'The coracoid bones, which constitute, at their contracted and thickened outer extremities, the remainder of the glenoid cavity, become suddenly and remarkably thinner and expanded as they pass inwards to articulate with the episternal bone. They are also complicated each in the young *Ichthyosauri* with an epiphysial piece wedged into the angle between their anterior margins and the episternum, which pieces correspond with the epicoracoids of the Lacertian *Sauria* and *Ornithorhynchus*. The existence of these bones I have determined in some of the beautifully worked-out skeletons in the collection of Mr Hawkins.

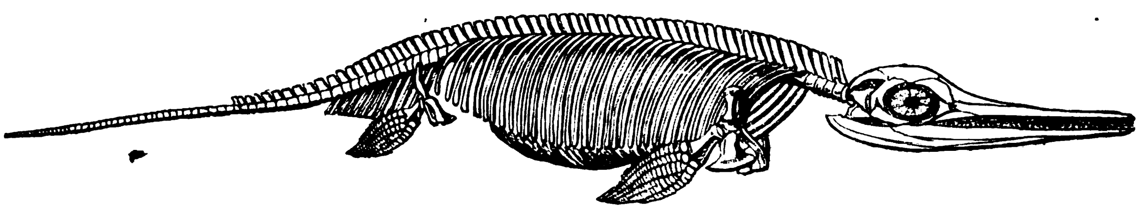
'The clavicles are strong, elongated, slightly curved bones, thicker in the middle than at their extremities, articulated by an oblique suture to the transverse processes of the episternum, with their median extremities in contact, but not anchylosed together as in the furculum of the bird: in this respect, as in their connection with the episternal bone, they correspond with the clavicles of the *Ornithorynchus*. In the entire mechanism of the complex pectoral arch indeed the resemblance between these very different animals is remarkably close, as Mr. Clift first pointed out, while the difference which both these air-breathing aquatic animals present in this part of their osseous structure from the *Cetacea* is very striking. In the *Cetacea*, for example, there is not any osseous bar interposed between the two shoulder-joints, or the centres on which the fore-paddle worked, while similar movements of the fore-paddles of the *Ichthyosaurus* and *Ornithorhynchus* had and have their momentum transferred to and resisted by not less than three transverse bones, viz. first, by the clavicles, secondly, by the episternal forks and the scapulæ, and thirdly, by the coracoids and scapulæ. To what difference in the habits of these species had these differences of structure reference? Most assuredly it could not relate exclusively to the necessity of rising to the surface to respire air, as conjectured by Sir Everard Home;* for this necessity existed in all the three types of aquatic animals, and much more imperatively in the *Cetacea* than in the *Enaliosauria*. In the *Ornithorhynchus* the anterior extremities are directed outwards, as in the marine *Cetacea* and *Enaliosauria*; but they are destined in that quadruped to be applied not only to displace water, but to be occasionally pushed against a more resisting surface, as the dry land: in order therefore to enable the fore limbs to react with due force upon the body, a strong apparatus of bone is introduced between the two shoulder-joints, whereby these parts are prevented from yielding inwards upon the soft muscular mass. But in the *Cetacea*, which were never intended to quit the deep, such an apparatus of bone, as it would have added unnecessarily to their weight, has been excluded from the mechanism of their anterior extremities: and hence it is that, when they have the misfortune to be stranded, they are unable to regain their native element. The instrument for bringing the head to the surface of the water for the purpose of breathing is the same in both the Monotreme and the Cetacean, viz. a strong muscular horizontally flattened tail. In the *Ichthyosaurus* a pair of hinder paddles (which in the large-headed species, as the *Ich. platyodon*, are equal in size with the fore-paddles) must have fully compensated for that different construction of the tail, which, while it rendered it less efficient as a means of raising the head to the surface, made it a more perfect instrument in ordinary natation; and the sufficiency of this compensation will be better appreciated when it is remembered that the reptilian structure of the lungs and heart of the *Ichthyosaurus* would allow it to dispense with so perfect a machinery for rising to the surface as was essential to the warm-blooded aquatic species above cited.

'For what purpose then were sterno-clavicular and coracoid arches assigned to the *Ichthyosaurus*? Doubtless that the anterior paddles might be subservient to locomotion not only in the water but on land; that when applied to the resisting soil, they might react with due force upon the trunk. It is very conceivable that the *Ichthyosaurus*, like the crocodile, may have come ashore to sleep: it is most probable that they resorted to the shore to deposit their eggs, supposing them to have been oviparous, as the sum of the analogies deducible from their osseous texture would indicate. The hind paddles would also be serviceable in terrestrial progression, as in the *Ornithorhynchus*, while in the strictly marine *Cetacea* they could readily be dispensed with.'

---

* 'Phil. Trans.,' 1818.

The number of species of *Ichthyosaurus* recorded by Professor Owen, amounts to ten, viz. *Ichthyosauri communis*, Con.; *intermedius*, Con.; *platyodon*, Con.; *lonchiodon*, Owen; *tenuirostris*, Con.; *acutirostris*, Owen; *latifrons*, Kœnig; *latimanus*, Owen; *thyreospondylus*, Owen; and *trigonus*, Owen



Skeleton of Ichthyosaurus—restored. (Conybeare, principally.)

Geographical Distribution, &c.—Professor Owen concludes a Report, which leaves nothing to be wished, by remarking that with respect to the geological relations of the *Enaliosauria*, or the extent of strata through which their relics have been traced, his researches are merely confirmatory of the generalisation already enunciated by Mr. Conybeare and Dr. Buckland. 'The British Enaliosaurs,' says Professor Owen, 'extend through the whole of the oolitic period, including the lias and oolite proper, to the wealden and chalk formations, the most recent depositary being the chalk marl, in which Ichthyosaurian remains have been discovered by Dr. Mantell, at Dover. Dr. Buckland has found similar remains in the gault near Benson, Oxon; and I have seen the humerus of a *Plesiosaurus* from the gault near Maidstone.' (*Report.*)

External Integument.—The tegumentary covering of the Plesiosaurus was in all probability similar to that of the *Ichthyosaurus*. (See ante, pp. 256, *n.*, 257, and ICHTHYOSAURUS, vol. xii., p. 433.) Mr. Swainson, in his 'Natural History and Classification of Monocardian Animals' (vol. ii., 1839), speaking of the *Ichthyosaurus*, says, 'We have no means of ascertaining the nature of its external skin, whether it was naked as in frogs, or hard as in crocodiles. The first conjecture however seems most probable.' In 1836, Dr. Buckland had published figures of portions of the integument of Ichthyosaurus, in his 'Bridgewater Treatise' (vol. ii., pl. 10, ff. 1, 2, 3, 4); and Sir Philip Grey Egerton is in possession of a hind-paddle of Ichthyosaurus, with its under side exposed, and showing the member covered with a skin, which reminds the observer of somewhat between the integument of a shark and that of a turtle on a similar part.

Place in the System.—MM. Duméril and Bibron arrange Plesiosaurus and Ichthyosaurus under their *Sauriens Aspidiotes fossiles*, an arrangement to which we cannot subscribe on account of their tegumentary covering, and for the reasons given in the article CROCODILE. [Vol. viii., p. 169.]

Hermann von Meyer places the genera between *Iguanodon* and *Mosasaurus*

Mr. Swainson makes the *Elanosaures* (*Enaliosauri*, or *Enaliosauria*, we suppose, is meant) the third order, arranging it between the order *Chelonides* (Tortoises) and *Ophides* (Serpents). In that part of the work headed 'Synopsis and Natural Arrangement of the Class of Reptilia,' Mr. Swainson's definition of the *Elanosaures, Fish Lizards*, is: 'Body lacertiform, feet fin-shaped, jaws exceedingly long;' and he arranges under it 'Plesiosaures' (*Plesiosaurus*), 'Ichthyosaures' (*Ichthyosaurus*), *Saurocephalus*, and *Pterodactylus*. In a subsequent part of the work, headed *A Natural Arrangement of the Class Reptilia*, the 'Elanosaures, Fish Lizards,' are thus defined:—'Lacertiform; feet in the form of fins, as in the aquatic turtles; tail short, compressed; the articulating surfaces of the vertebræ concave; eyes very large, nocturnal.' The genera comprising the order *here*, are *Ichthyosaurus, Plesiosaurus*, and *Saurocephalus*, Harlan; *Pterodactylus* being omitted.

By microscopical examination of a tooth of the fossil presented to him by Dr. Harlan, Professor Owen has proved the *Saurocephalus* to be a true osseous fish, nearly allied to, if not actually a Sauroid fish, as M. Agassiz had previously conjectured.

Professor Owen's opinion of the zoological situation of the Enaliosaurians, will be seen in the excellent Report from which we have drawn so largely.

PLESKOW. [PSKOW.]

PLE'STIODON, a name given by MM. Duméril and Bibron to a genus of their Scincoidian Lizards, or Lepidosauri (Saurophthalmes)—*Euprepis* of Cocteau, Euprepis, part, of Wagler—which they thus characterise:—

Nostrils opening in the middle or nearly in the middle of the nasal plate; two supero-nasal plates. Palate with a wide median groove, opened out at its anterior extremity; pterygoidian teeth; scales smooth.

PLETHO'RA (a Greek word, πληθώρη, *plethóre*, fulness, in which sense it is used by the Greek medical writers) signifies a redundancy of blood. By the older writers the term was used to express an imagined superabundance of any of the fluids of the body; and the terms bilious, lymphatic, and milky plethora, &c., implied the existence of an excess of one or other of those fluids in the blood. Distinctions were also made, and by a few are still retained, between plethora from excess of blood, from insufficient capacity of the vessels, from deficient strength, and so on. By the majority of the physicians of the present day however, the term plethora is used only to express that condition in which the quantity of blood and its nutritive qualities exceed that standard which is compatible with present or the prospect of continued health.

Plethoric persons are marked by a florid ruddy complexion, a full hard pulse, a tendency to hemorrhage from the nose or other parts, a frequent sensation of fatigue and weight in the limbs, a disposition to sleepiness, and by being in what is commonly termed good condition. In this degree plethora cannot be regarded as more than giving a tendency to disease whenever any slight occasional cause is applied. In a greater degree however, it produces effects which are in themselves important: the complexion is yet fuller and more florid, the face seems swollen, and the eyes blood-shot, there is pain in the head, with giddiness, ringing in the ears, dullness, heavy sleep, and a sensation as of flashes before the eyes, inability of exertion, constant feeling of fatigue, and frequent palpitation of the heart.

Such a condition, to which some persons seem from birth peculiarly predisposed, may be produced in nearly all by the constant use of very nutritious food, by gluttony or excess in beer, by indolence, or by the insufficiency or suppression of some habitual discharge. Its principal evil is that it renders the person who is affected by it peculiarly liable to acute inflammations and to hemorrhages in important organs, as the brain, in which the latter produce apoplexy. To avoid such consequences, a less nutritious diet, abstinence from exciting drinks, and the regular employment of active exercise are commonly sufficient; but in more advanced and in extreme cases of plethora, blood must be drawn freely both from the arm and from the neighbourhood of any organ in which there seems a peculiar disposition to its accumulation, or from which it was once habitually discharged; active aperients should also be administered, and the diet should be reduced to a much lower scale than that which had the chief share in engendering the disorder.

PLEURA is the membrane which envelopes the lungs and lines the cavities of the chest. On the walls of each cavity of the chest the pleura costalis (as it is here called) is formed by a sheet of fine and elastic cellular tissue, loosely attached to the ribs, intercostal muscles, and other subjacent parts. On the exterior of the lung the pleura pulmonalis is composed of a thin superficial layer of fine cellular tissue, and a deeper layer of coarser fibrous tissue, which in most of the large quadrupeds, and in the seal and some other animals, is very elastic, and affords an important assistance in the act of expiration. The surfaces of the two portions of pleura are continuous with each other at the root of the lung; each is covered with a delicate layer of epithelium; and they enclose within them a space called the sac of the pleura, into which a small quantity of serous fluid is constantly secreted, which moistens the opposite surfaces of the lung and of the wall of the chest, and permits their free motion upon each other. [MEMBRANE.]

PLEURISY, a word derived immediately from the French *Pleurésie*, which comes from the Greek πλευρῖτις, and this again from πλευρὸν, *the side*, which is defined by Rufus Ephesius (*De Corp. Hum. Part. Appell.*, pp. 30, 51, ed. Clinch) to mean πᾶν τὸ ὑπὸ τῇ μασχάλῃ, 'all that part which is under the arm-pit.'[*] As this is one of the diseases of which both the nature and the treatment were understood by the antients almost as perfectly as by ourselves (except of course that they had not the assistance of auscultation and percussion to help them in forming their diagnosis), it may be as well to give in their own words those passages which have been repeated with more or less alteration by every succeeding writer on the subject, omitting those which are either erroneous from their less accurate knowledge of anatomy, or which rest only upon some fanciful theoretical speculation, and adding whatever may be necessary to bring the article as far as possible up to the level of the present state of medical science.

'Pleurisy, properly so called,' says Paulus Ægineta (*loco cit.*, in Mr. Adams's translation, 8vo., London, 1834), 'is an inflammation of the membrane which lines the ribs, and is attended with difficulty of breathing, cough, continual fever, and pain shooting to the clavicle and hypochondrium,' which definition agrees with that given by Galen (*De Loc. Affec.*, lib. v., cap. 3, p. 326, ed. Kühn; *Ad Glauc. de Med. Meth.*, lib. ii., cap. 1, p. 77; *Introd.*, cap. 13, p. 734; *Definit. Med.*, § 264), Aretæus, Aëtius, and Alexander Trallianus (*locis cit.*). The disease has been variously divided by different writers; Dr. Good (*Study of Med.*) mentions the three following varieties:—1, Pleuritis Vera, True Pleurisy. Fever, a cauma; pain felt chiefly on one side, the inflammation commencing in that part of the pleura which lines the ribs. 2, Pleuritis Mediastina, Pleurisy of the Mediastinum. Heavy pain in the middle of the sternum, descending towards its ensiform cartilage; with great anxiety; the inflammation, from its symptoms, being obviously seated in the mediastinum. 3, Pleuritis Diaphragmatica, Pleurisy of the Diaphragm. Painful constriction around the præcordia; small, quick, laborious breathing; manifesting that the inflammation is seated chiefly in the diaphragm. He adds however, that the subdivisions lead to nothing of practical importance, as the causes are nearly alike, and the same mode of treatment is applicable to the whole. A more essential distinction is that adopted by Dr. Law (*Cyclop. of Pract. Med.*), viz. acute and chronic, and this will be followed here, because it seems almost impossible to treat either of the nature or the treatment of these two forms of pleurisy under one and the same head.

In acute pleurisy, says Aretæus (*loco cit.*, in Dr. Reynolds's translation, 8vo., London, 1837), 'we have acute pain in the clavicular region, together with a sharp burning heat; the recumbent posture is easy on the inflamed side, because there the membrane remains in its place, but to lie on the opposite one is exceedingly painful, and from the weight, inflammation, and dragging, the pain extends through the whole continuity of membrane to the shoulders and clavicles, in some even to the back and shoulder-blades. To this succeed dyspnœa, watchfulness, loathing of food, bright redness of the cheeks, a dry cough, difficult expectoration. To this description it may be added, from Paulus Ægineta, that 'the pulse is hard and serrated;' and it should be noticed that the *decubitus*, or position of the patient, mentioned by Aretæus and repeated by numerous modern writers, is not constant, and therefore cannot bo exclusively relied upon as a diagnostic sign, for it is sometimes observed that the aggravation of the acute lancinating pain caused by the pressure when lying upon this side, makes the patient seek a more easy position either upon the opposite one or upon the back.

With respect to the diagnosis of pleurisy, it may be distinguished from hepatitis, says Paulus Ægineta, by the pain in pleurisy being pungent, and the cough being sometimes without expectoration and sometimes with it, and by the pulse being hard and serrated; while in inflammation of the liver the pain is not pungent, nor is the pulse so hard, and the cough throughout is dry and without expectoration, and the face appears pale. (Compare Alex. Trall., *loco cit.*) It may be distinguished from inflammation of the external muscles, or pleurodynia [PLEURODYNIA], by the latter affection being (according to the same author) unaccompanied with cough and expectoration, nor is the pulse hard. From pneumonia it is hard to distinguish it without calling in the aid of auscultation and percussion, and indeed Dr. Cullen, in his 'Practice of Physic,' has treated of both these affections under one common definition. It may however be observed (with Dr. Good) that in pleurisy the face is comparatively but little flushed, and far less tumid than in pneumonia; that the pulse is harder, and that the seat of the pain is fixed, while in pneumonia it shifts not only to different parts of the same side, but often from the one side to the other. The characteristic cough of pleurisy (as distinguished from that which follows pneumonia) is a short cough, either dry from the beginning to the end, or accompanied with a thin mucous expectoration; should the sputa be more abundant, or deviate from this character, we may suspect a complication either of pneumonia or bronchitis. The cough however (adds Dr. Law) is often wanting altogether, or is so slight as to attract the attention of neither the patient nor physician. For the characteristic signs of pneumonia derived from auscultation and percussion the reader must see the article LUNGS, DISEASE OF THE, while only those relating to pleurisy will be given here. Upon auscultation the inspiration will appear feeble, distant, or inaudible, but will be restored by change of posture. *Ægophony* will exist when the quantity of fluid effused is no more than forms a thin layer between the lungs and parietes of the chest. The *bruit de frottement*, or *sound of friction*, will be heard when there is partial albuminous exudation with little or no effusion of serum. Upon percussion there will be more or less loss of sound, with moderate resistance, decreasing from below upwards; and this dulness will be diminished or removed by change of position. It was in cases of pleuritic effusion that Hippocrates proposed the succussion, or shaking of the chest, as a means of assisting the diagnosis (*De Morb.*, lib. i., p. 173, ed. Kühn; *ibid.*, lib. ii., pp. 256, 258; *Coac. Prænot.*, p. 306; *De Loc. in Hom.*, pp. 123, 124); but it is now known that no sound can be heard unless air be present in the chest at the same time,—that is, unless empyema be combined with pneumothorax, which is a rare occurrence.

With respect to the anatomical characters of pleurisy, they agree with what may be observed in inflammation of all serous membranes, and consist partly in morbid alterations of the pleura itself, and partly of the secreted fluid. Inflammation of the pleura, says Laennec, is always accompanied by an extravasation on its internal surface; the matter effused being either coagulating lymph termed a *false membrane*, or else serosity, or a sero-purulent fluid. The false membrane, or exudation of lymph, is gradually changed into cellular substance, or rather into a true serous tissue, like that of the pleura. The serous effusion is absorbed, the compressed lung expands, and the false membrane investing it and the pleura costalis become united into one substance, which afterwards becomes vascular and organised, and constitutes permanent adhesions. A severe pleurisy that has terminated by numerous adhesions, renders the part so effected much less liable to subsequent attacks of the same disease; and when it occurs, the inflammation and effusion do not extend to the adherent parts.

Among the occasional causes of pleurisy, enumerated by Laennec (after Celsus), are,—long exposure to cold after violent exercise; metastasis of gout, rheumatism, and cutaneous diseases; blows on the chest; and fracture of the ribs. 'The winter season,' says Aretæus, 'is most liable to produce this disease, and next to it the autumn; the spring is less so, unless it chance to be a cold one, while the summer is the least so of all.' In reference to the period of life, he remarks that old people are more liable to it than those who are in the prime of life; and these again than children. Among predisposing causes, Laennec mentions a slender frame, narrowness of the chest, the immoderate use of spirits, and tubercles in the lungs.

---

[*] The word πλευρῖτις is generally said to be derived from πλευρά, *the pleura*, but (as far as the writer is aware) the word πλευρὰ is never used by the antient medical writers in that sense. That which is called *the pleura* by modern anatomists is called ὑπεζωκὼς ὕμην, or simply ὑπεζωκὼς by Aretæus (*De Caus. et Sign. Morb. Acut.*, lib. i., cap. 10, p. 20, ed. Kühn), Aetius (lib. viii., cap. 76, p. 175. B., ed. Ald.), Alexander Trallianus (lib. vi., cap. 1, p. 85, ed. Steph.), and Paulus Ægineta (lib. iii., cap. 33, p. 41, B., ed Ald.). Galen uses the same word in more than one place, and with regard to its meaning says (*De Anatom. Administr.*, lib. vii., cap. 2, p. 591, ed. Kühn), 'As the other membrane is called the peritonæum (περιτόναιον), because it is extended around (ἀπὸ τοῦ περιτετάσθαι) the alimentary vessels, so this (i e. *the pleura*) is called ὑπεζωκὼς, because it fastens together internally (ἔσωθεν ὑπέζωκε) the whole of the ribs.'

Pleurisy terminates either in resolution, suppuration, or gangrene. The former is the ordinary and most favourable issue. The last occurs rarely, and Laennec has seen only one instance of it from acute inflammation. Suppuration however is by no means uncommon, in which case, says Aretæus, 'shivering fits ensue, and lancinating pains, accompanied with a desire to sit in an upright posture; the breathing gets worse, and there is great fear lest the lung, by suddenly drawing in the purulent matter, should produce suffocation, after the previous and greater danger has been escaped; should the matter however burrow between the ribs and separate them, and either point externally or burst into the bowels, the patient usually recovers.'

With respect to the treatment, perhaps there is no disease in which profuse bleeding from a large orifice may be so fully depended upon, or has been so generally acceded to by practitioners of all ages and all nations; the only question which has ever arisen upon the subject being, whether the blood should be taken from the side affected, or from the opposite. Hippocrates and most of the earlier Greeks recommended the former, while the latter method was practised by Archigenes (*ap. Aëtium*, tetrab. ii., serm. 4, cap. 68), Avicenna (*Canon*, lib. iii., fen. 10, tract. 5, cap. 1), Avenzoar (*Teisir*, lib. i., tract. 16, cap. 3, p. 23, D., ed. Venet., 1549), and their followers in the middle ages. The dispute, which is one of those that have been settled by the discovery of the circulation of the blood, was before that time (as may easily be imagined) considered to be of the greatest consequence, and at the beginning of the sixteenth century raised a kind of civil war (as Bayle says) among the Portuguese physicians on account of the controversy between Denys and Brissot, the particulars of which are too curious to be altogether omitted. The dispute was brought at last before the tribunal of the university of Salamanca, where it was canvassed in a most profound manner by the body of physicians; but in the meantime the partisans of Denys, who were the more powerful, obtained a decree from the civil authorities forbidding physicians to bleed on the same side on which the pleurisy was. At last the university of Salamanca gave judgment, and decided that Brissot's opinion was the pure doctrine of Hippocrates and Galen. The other party removed the cause before the emperor Charles V., 1529; and were not satisfied with exclaiming against the doctrine of Brissot as false, but declared it to be impious and deadly, and that it was no less pernicious to the body than Luther's schism to the soul. Unluckily for them just about this time Charles III., duke of Savoy, happened to die of a pleurisy, after having been bled pursuant to the practice which Brissot had opposed. This put a stop to the appeal to the emperor, but books were written on the question in all parts of Europe, and the practice of the Arabians was generally condemned. A list of these treatises is given by René Moreau, in the Life of Brissot, prefixed to his edition of his work 'De Incisione Venæ in Pleuritide Morbo,' &c. Paris, 1622, 8vo. (See Bayle, art. 'Brissot,' from whom the above account is abridged.)

Besides blood-letting (which may be repeated at proper intervals, as long as the pain remains), the usual antiphlogistic remedies, such as saline diuretics, diaphoretics, purgatives, mercurials, blistering, &c., may be employed; in cases of acute pleurisy the operation of paracentesis thoracis is very seldom had recourse to, and is hardly ever attended with more than a temporary relief.

Chronic pleurisy is either the continuation, as it were, of the disease in its acute form, or else exhibits at no period either the intense fever, the violent pain, or energy of reaction which characterise an acute disease. In this latter form it creeps on very insidiously, without much acceleration of pulse or heat of skin; the pain in the side amounts to no more than a mere soreness; and the difficulty or hurry of breathing is sometimes so inconsiderable as not to attract the individual's attention. However, his unhealthy pallid appearance, his loss of appetite, and languid look emphatically tell of mischief going on, and upon close examination it is found that the absence of fever is not constant, but that towards evening there is a febrile movement.

The anatomical characters of chronic pleurisy do not differ very widely from those of the acute form, especially when it has been a mere transition of one form of the disease into the other. The fluid effused however partakes more of a purulent character, and the false membrane is firmer and more condensed, owing perhaps to the longer time it has been under the pressure of the effused fluid. The lung too is more compressed than in acute pleurisy, so much so that there is sometimes a complete annihilation of its vesicular structure, and the organ itself is reduced to a thin lamina, not exceeding six lines in thickness, lying down along the spine.

The prognosis of chronic pleurisy is, generally speaking, very unpromising: in the ordinary course of the disease a slow wasting fever sets in; there is a gradual emaciation; the appetite fails; the pulse is languid, although not much quickened; the legs swell, and the face becomes puffed; the expectoration often has a disagreeable alliaceous smell. Under these symptoms well-defined hectic fever soon supervenes, and rapidly wears down the patient.

The treatment of chronic pleurisy differs (as might be supposed) very materially from that of the acute form of the disease. Blood-letting is hardly ever resorted to, for the weakened habit of body will not bear the exhaustion of it. For promoting the absorption of the effused fluid, as well as for preventing its further secretion, external applications, comprehending the different modifications of counter-irritation, *e.g.* blisters, setons, issues, stimulating liniments, &c., appear to be most efficacious. In some cases however the operation of paracentesis thoracis seems to be the last resource, and this so often fails that it is by some practitioners considered an almost hopeless experiment. In trying to improve the habit of body and to relieve the constitutional symptoms, which most commonly accompany this form of the disease, recourse must be had to a nutritious but not a heating or exciting diet, and to the cautious exhibition of such tonics as the patient is able to bear. Change of air is often productive of the most decided benefit, and sometimes effects an almost instantaneous amelioration in the symptoms, by causing the night perspirations to cease, the appetite to improve, and the sleep to become refreshing.

(See, besides Good, *Study of Med.*, and Law, art. 'Pleurisy,' in *Cyclop. of Pract. Med.* (from which two works much of this article is abridged), Cruveilhier, art. 'Pleurésie,' in *Dict. de Méd. Prat.*, 1835, and Laennec *On Diseases of the Chest*, translated by Forbes. Besides the antient authors already quoted, the following references are given by Mr. Adams, in his 'Commentary to Paulus Ægineta:' Celsus, *De Med.*, lib. iv., cap. 6; Psellus, *De Vict. Ratione;* Oribasius, *Collecta Medicin.*, lib. ix., cap. 7, 8; Joannes Actuarius, *Meth. Med.*, lib. iv., cap. 4; Theophanes Nonnus, cap. 129; Cælius Aurelianus, *De Morb. Acut.*, lib. ii., cap. 13; Octavius Horatianus, *Rer. Med.*, lib. ii., cap. 4; Marcellus Empiricus, *De Medicam.*, cap. 24; Serapion, *Pract.*, ii. 21; Mesue, *De Ægrit. Pect.*, cap. 7; Alsaharavius, *Pract.*, lib. xii., cap. 8; Haly Abbas, *Theor.*, lib. ix., cap. 21; *Pract.*, lib. vi., cap. 13; Rhazes, *Lib. Divis.*, cap. 54; *Contin.*, lib. x.)

A very complete list of works on the subject of Pleurisy is given in Ploucquet, *Literatura Medica Digesta*, 4 vols. 4to., Tübing., 1808-9; and a selection in the Appendix to the *Cyclop. of Pract. Med.*

PLEUROBRANCHÆA. [SEMI-PHYLLIDIANS.]

PEUROBRANCHUS. [SEMI-PHYLLIDIANS.]

PLEURODICTYUM. Goldfuss employs this term for a species of coral? from the transition rocks of the Hundsruck. (*Petrefacten*, tab. 38, f. 18.) It is said by Mr. Austen to occur in Devonshire.

PLEURODONTS. MM. Duméril and Bibron make their *Iguaniens Pleurodontes* the first subfamily of the *Iguanian Lizards*, or *Sauriens Eunotes*.

This tribe corresponds to that designated by Wagler under the names of *Pachyglossæ platycormæ* and *Stenocormæ Pleurodontes*, and by Wiegmann under those of *Pachyglossæ Dendrobatæ* and *Humivagæ Prosphyodontes*.

The maxillary teeth of the species composing the *Pleurodonts* have their summit, or free and enamelled part, more or less trilobated. There are only some genera in which the teeth are dentilated on the edges; nearly all have the palate armed with teeth, disposed in one or two rows on each side. Sometimes the tympanic membrane is stretched on the level of the auditory conduit, whose edge is either simple or dentilated, and sometimes it is a little sunk within it. None of the known species are without an external ear. Among these *Pleurodont Iguanians* alone are met with species whose toes are enlarged nearly in the same manner as in some of the *Geckos*. [Gecko.] All the *Pleurodont Iguanians*, with the exception of one genus only (*Brachylophus*), are natives of the New World.

The following genera are arranged under this subfamily by MM. Duméril and Bibron:—

1. *Polychrus*, Cuv. *Generic Character*.—Skin of the lower region of the neck forming a longitudinal fold, or a sort of small dewlap, dentilated in front. Palatine teeth. Femoral pores. Fourth toe of the same length as the third. Scales of the body entirely or partially imbricated and carinated. Tail not prehensile. Neither dorsal nor caudal crest.

2. *Læmanctus*, Wiegm. *Generic Character*.—Skin of the lower region of the neck forming a transversal fold in front of the breast. Neither palatine teeth nor femoral pores. Fourth toe longer than the third. All or part of the scales of the body imbricated and carinated. Tail not prehensile. Neither back nor tail crested.

3. *Urostrophus*, Dum. and Bib. *Generic Character*.—Skin of the lower region of the neck forming a transversal fold in front of the breast. Palatine teeth. No femoral pores. Fourth toe longer than the others. All the scales of the body smooth; those of the belly flat and imbricated; the others convex and in juxta-position. Tail prehensile.

4. *Norops*, Wagl. *Generic Character*.—Skin below the neck forming a projecting fold, or a sort of small non-dentilated dewlap. No palatine teeth nor femoral pores. Fourth toe longer than the third. Scales of the body carinated, imbricated in part; those of the sides much smaller than those of the back and belly. Tail moderate, not prehensile, without a crest, like the back.

5. *Anolis*, Daud. (*Anolis*, Merr.; *Anolius*, Cuv.; *Dactyloa*, Wagl.; *Draconura*, Wagl. and Wiegm.; *Xiphosurus*, Fitzing.). *Generic Character*.—Toes dilated under the antepenultimate phalanx, forming a suboval disk more or less enlarged, furnished with imbricated scaly lamellæ. Under the neck a *goître*, which, when it is not expanded, takes the form of a more or less developed dewlap. Palatine teeth. No pores to the thighs.

The species are numerous. MM. Duméril and Bibron record twenty-five.

6. *Corythophanes*, Boie (*Corythophanes*, Wiegm., Gravenhorst; *Chamæleopsis*, Wiegm., Graven., Gray). *Generic Character*.—Toes not dilated, nor fringed on their external border. Posterior part of the cranium more or less elevated into a sort of casque. Palatine teeth. Tail long, somewhat rounded or very feebly compressed, without a crest. Back, and sometimes the nape, crested. Under the neck a transversal fold, in front of which is a rudiment of a dewlap, which is sometimes denticulated. No femoral pores.

7. *Basiliscus*, Laur. (*Basiliscus*, Wiegm.; *Corythæolus*, Kaup.; *Œdicoryphus*, Wagl.). *Generic Character*.—A fragment of triangular skin elevating itself vertically above the occiput. External edge of the posterior fingers furnished with a scaly dentilated fringe. Back and tail surmounted sometimes (in the males) with an elevated crest, sustained in its thickness by the spinous or upper apophyses of the vertebræ. Under the neck a rudiment of a dewlap, succeeded by a well-marked transversal fold. Palatine teeth. No femoral pores. [Basilisk.]

8. *Aloponotus*, Dum. and Bib. *Generic Character*.—Skin of the upper part of the trunk without scales. A small dewlap, without dentilations. Tail compressed, furnished with great carinated verticillated scales. Two rows of femoral pores. Palatine teeth. Maxillary teeth with a trilobated summit. A very low dorsal and caudal crest. Cephalic plates small, equal, flat, and polygonal.

9. *Amblyrhynchus*, Bell (*Amblyrhynchus*, Gray and Weigm., but not Wagler). *Generic Character*.—Body covered with scales elevated into tubercles. Throat dilatable, but without a dewlap. Tail compressed towards its extremity, and furnished with great verticillated scales. A row of pores under each thigh. Palatine teeth? Maxillary teeth lateral, with a trilobated summit. A rather high paleaceous crest on the back and tail. Head covered with unequal tubercles, with a polygonal base. Toes stout and short.

10. *Iguana*, Laur. (*Hypsilophus*, *Amblyrhynchus*, Wagl.). *Generic Character*.—A very large delicate dewlap under the neck. Cephalic plates polygonal, unequal in diameter, flat or carinated. A double row of small palatine teeth. Maxillary teeth with their edges finely dentilated A crest on the back and tail. Toes long and unequal. A single row of femoral pores. Tail very long, slender, compressed, covered with small, equal, imbricated, carinated scales. [Iguana.]

11. *Metopoceros*, Wagl. (*Iguaan*, Cuv.). *Generic Character*.—Throat dilatable, but without a dewlap. Some tuberculose plates on the muzzle. Palatine teeth. Maxillary teeth with a tricuspidate summit. Back and tail crested. A double row of femoral pores. Tail long, compressed, covered with equal scales, which are imbricated and carinated, but not spiny.

12. *Cyclura*, Harlan (*Iguana*, Cuv. and Merrem, part; *Ctenosaura*, Wiegm. and Gray, part; *Cyclura*, Wagl., Wiegm., Gray.). *Generic Character*.—Skin of the throat loose, plaited across, but without the true dewlap of the *Iguanæ*. Cephalic plates angular, flat, or convex. Palatine teeth. Maxillary teeth with a trilobated summit. A single row of femoral pores. Back and tail crested; the last more or less compressed, furnished with verticillated scales, alternating with rings of spines.

13. *Brachylophus*, Cuv. *Generic Character*.—Skin of the throat loose, slightly pendulous longitudinally. Cephalic plates very small, polygonal, equal, and flattened. Scales of the upper part of the trunk granulous. Palatine teeth. Maxillary teeth dentilated on the sides. A single row of pores under each thigh, a very low crest running the whole length of the back. Tail very long, very slender, compressed at its base, rounded throughout the rest of its extent, furnished with small, equal, carinated, imbricated scales, and without a crest.

14. *Enyalius*, Wagl. (*Ophryoëssa*, part, Gray, Wiegm.). *Generic Character*.—Head short, covered with small, equal, polygonal plates. A dorsal crest. Palatine teeth. No femoral pores. Tail rounded, without a crest.

15. *Ophryoëssa*, Boie. • *Generic Character*.—Head short, covered above with small polygonal plates, nearly similar to each other in figure and diameter. Nostrils lateral. Sincipital plate small. Palatine teeth. No femoral pores. Tail pressed throughout its length, and surmounted, as well the back, with a dentilated crest. Skin of the throat forming a not very perceptible fold, behind which is a strongly marked transversal one.

16. *Leiosaurus*, Dum. and Bib. *Generic Character*.—Head short and depressed, covered with very small flat or convex scales. No crest on the upper part of the body. Palatine teeth. No femoral pores. Tail short, rounded. Anterior toes short, stout, subcylin drical, furnished below with a row of smooth or carinated scales.

17. *Uperanodon*, Dum. and Bib. (*Plica*, Gray, part; *Hypsibatus*, Wagl., part). *Generic Character*.—Head short, rounded anteriorly, covered with scales unequal in diameter; a large occipital scale; great subocular scutella. Nostrils lateral. No palatine teeth. A well-marked transversal fold, preceded by another which is longitudinal and hardly perceptible. Trunk subtriangular, not plaited laterally, surmounted by a small crest, and covered with imbricated carinated scales. Tail moderately long, rounded, without a crest. No femoral pores.

18. *Hypsibatus*, Wagl. (*Plica*, Gray). *Generic Character*.—Head depressed, rounded anteriorly, covered with unequal plates; a great occipital scale; great subocular plates. Nostrils lateral. Palatine teeth. A longitudinal fold under the throat; another transversal fold in front of the breast. Trunk a little depressed, with two longitudinal folds on each side of the back. Bundles of spines on the nape and round the ears. A dorsal crest. Scales of the body carinated and imbricated. Tail rounded or compressed. No femoral pores.

19. *Holotropis*, Dum. and Bib. (*Tropidurus*, Fitzing., part; *Leiocephalus*, Gray). *Generic Character*.—Head in the shape of a quadrangular pyramid. Cephalic plates moderate, angular, nearly equal; a very small occipital plate; subocular scutella dilated across; the other plates oblong. Palatine teeth. Neck smooth below, plaited irregularly on the sides. An oblique fold of the skin before each shoulder. Anterior border of the ear dentilated. Trunk subtrihedral, covered with imbricated scales of moderate size, surmounted with carinations finishing in a sharp point, and forming oblique lines converging towards the middle of the back. A dentilated crest extended from the nape to the extremity of the tail, which is long and compressed. External border of the first two or three posterior fingers dentilated. No pores at the cloaca nor on the thighs.

20. *Proctotretus*, Dum. and Bib. (*Tropidurus* (*Leiolæmus*),

Wiegm.). *Generic Character.*—Head subpyramidal, quadrangular, more or less depressed. Cephalic plates moderate, polygonal; occipital plate in general not very distinct. Palatine teeth. Neck plaited on the sides, or entirely united. Membrane of the tympanum rather sunk. Body rounded or slightly depressed, covered with imbricated scales, the upper ones carinated, the lower smooth. Neither caudal nor dorsal crest. Toes simple. Tail long and conical, or moderate and slightly depressed. No femoral pores; anal pores in the males.

21. *Tropidolepis*, Cuv. (*Sceloporus*, Wiegm.; *Tropidurus*, part, Wagl.). *Generic Character.*—Head short, flattened, rounded in front; a great occipital scale and large subocular plates. No palatine teeth. Below the neck on each side a sort of oblique slit. Trunk short, depressed, with imbricated scales, carinated on the back, smooth under the belly. No dorsal nor caudal crest. Tail stout, not much elongated, depressed at the base, rounded after. Femoral pores, but no anal pores.

22. *Phrynosoma*, Wiegm. (*Agames orbiculaires*, Daud., part; *Tapayes*, Cuv., Fitzing.). *Generic Character.*—Head short, rounded anteriorly, bordered posteriorly and laterally with large and strong prickles. Cephalic plates polygonal, equal; a small subcircular occipital plate. No palatine teeth. Beneath the neck plaited transversely. Border of the ear simple. Trunk short, oval, very much depressed, offering on each side a squamous dentilated arête. Upper part bristling with trihedral tubercles springing in the middle of small imbricated scales. Neither dorsal nor caudal crest. Limbs very short; toes but little developed, dentilated on their borders. Tail hardly so long as the trunk, flattened, very wide at its root. A line of pores on each thigh.

23. *Callisaurus*, Blainv. *Generic Character.*—Head short, depressed, rounded anteriorly, covered with unequal plates; a very much dilated occipital scale, and great subocular scutella, which are nearly square. Nostrils situated on the muzzle. No palatine teeth; all the maxillary teeth simple and conical. A longitudinal fold under the throat, followed by another which is transversal. Foldings on the sides of the neck. Borders of the auditory holes simple. Trunk not much elongated, compressed, enlarged on each side by a development of the skin. Scales of the body small, numerous, serrated, imbricated, united. Neither dorsal nor caudal crest. Tail long, flattened, wide at its origin, narrowed throughout the rest of its extent. Limbs but little developed; toes very long and very narrow; nails very loose (effilés). A long row of pores upon each thigh.

24. *Tropidogaster* (Dum. and Bib.). *Generic Character.*—Head short, triangular, obtuse anteriorly. Subocular regions covered with a great number of polygonal plates much smaller than the other cephalic scales, and carinated like them. A moderate occipital scutellum. Nostrils lateral, tubular. No palatine teeth. Throat with two or three transverse entire folds. One or two longitudinal plates on the sides of the neck. Membrane of the tympanum a little sunk. Anterior border of the ear subdenticulated. Trunk very slightly depressed; a fold of the skin along each side. Scales of the back small, unicarinated, and with their borders, as it were, swollen; scales of the belly with three carinations. A small dentilated crest from the occiput to the end of the tail, which is long, subconical, very slightly depressed at its base, and surrounded with verticillated carinated scales. Toes and nails slender, very loose (effilés). No femoral pores.

25. *Microlophus*, Dum. and Bib. (*Tropidurus*, part, Wiegm.). *Generic Character.*—Head subpyramido-quadrangular, depressed, with plates unequal in diameter; a very dilated occipital scale; great subocular scutella. Nostrils lateral and rather tubular. Palatine teeth. Many cross folds under the neck. In front of each shoulder an arched fold descending on the breast, without uniting itself with that which is opposed to it. Anterior border of the ear dentilated. Trunk elongated, slightly rounded, with subimbricated scales slightly carinated or united on the back, tiled and smooth under the belly. Skin of the side of the body forming two longitudinal folds. A very low dentilated or tubercular crest extending from the nape to the extremity of the tail, which is long, subconical, and with carinated subverticillate scales. No femoral pores.

26. *Ecphymotes*, Cuv., not Fitzing. (*Tropidurus*, Wied., Wiegm., Wagl., part; *Oplurus*, Gray, part). *Generic Character.*—Head triangular, depressed, covered with unequal plates; a rather dilated occipital scale; moderate subocular scutella. Nostrils rather lateral, slightly tubular, and directed backwards. A single transversal plate beneath the neck, and two strongly marked ones on each side. Palatine teeth. Trunk not much elongated, depressed, with small imbricated scales; the under ones smooth; those above surmounted with carinæ, forming converging lines towards the medio-longitudinal region of the body. Neither dorsal nor caudal crest. Limbs of moderate length. Tail rather long, strong, conical, with subverticillate scales, which are imbricated and carinated. No femoral pores.

27. *Stenocercus*, Dum. and Bib. *Generic Character.*—Head depressed, triangular, elongated, covered with small equal plates; occipital scale hardly distinct; subocular scutella forming many longitudinal rows. Palatine teeth. Nostrils sublateral, tubular, directed backwards. A curvilinear cutaneous fold before each shoulder. No transversal folds under the neck, the sides of which are plaited longitudinally. A very small dentilated crest extending from the nape to the tail. Trunk rather elongated, subtrihedral, with imbricated scales, smooth below, offering above carinæ disposed in oblique lines; tail rather long, compressed, surrounded with verticillations formed by great spiny scales. No femoral pores.

28. *Strobilurus*, Wiegm. *Generic Character.*—Head depressed, covered with a great occipital plate, surrounded with a great number of small scutella. No palatine teeth. Membrane of the tympanum rather sunk; anterior border of the ear dentilated. An oblique plait of the skin before each shoulder; ramified plications on the lateral parts of the neck. Trunk subtrihedral, with moderate scales, which are imbricated, carinated on the back, smooth under the belly. The *arêtes* of the upper scales forming oblique lines converging towards the rachidian region. A dentilated keel extending from the neck to the base of the tail, which is moderate, rather compressed, and covered with great spiniferous scales. No femoral pores.

29. *Trachycyclus*, Dum. and Bib. *Generic Character.*—Head quadrangularly pyramidal, flattened, covered with nearly equal plates; occipital scale very small. Nostrils rather lateral. No palatine teeth. An arched fold before each shoulder. Skin of the lower part of the neck tense; those of the sides plaited longitudinally; cervical, dorsal, and caudal regions without a crest. Trunk nearly round, with the scales rather large, imbricated, carinated above, smooth below. Tail of moderate length, subconical, very slightly depressed at its base, surrounded with verticillations of spines. No femoral pores.

30. *Oplurus*, Cuv. (*Tropidurus*, Wiegm., Fitzing., Gray, part). *Generic Character.*—Head triangular, but little elongated, thick, furnished with plates of moderate size; occipital plate moderate; subocular plates smaller than the others, and disposed in many rows. Nostrils rather lateral and tubular. Palatine teeth. Membrane of the tympanum sunk in the ear, the anterior border of which last is dentilated. A transversal fold at the origin of the breast ascending on each shoulder, and sometimes preceded by two others. Neck surmounted by a very small crest. Trunk short, wide, with smooth or carinated scales. Tail stout, of moderate length, slightly conical, surrounded by verticillations formed by great and strong spiny scales. No femoral pores.

31. *Doryphorus*, Cuvier (*Urocentron*, Kaup, Wagl., Wiegm.). *Generic Character.*—Head short, triangular, flattened anteriorly. A great occipital plate; scales polygonal, small, nearly equal on the rest of the cranium No palatine teeth. Under the neck a double transversal entire fold. Ears not dentilated. Nasal plates nearly lateral and convex. No crest on the upper part of the body. Trunk short, depressed, convex above, plaited longitudinally on the sides, and with small imbricated smooth scales. Tail but little elongated, stout, flattened, surrounded with strong spiny verticillated scales. No femoral pores.

The generic characters of this extensive subfamily here given are those of MM. Duméril and Bibron. A few of the most remarkable forms have already been illustrated in this work. [IGUANIDÆ.]

PLEURODY'NIA (from πλευρά, the side, and ὀδύνη, pain—pain of the side), called also 'false pleurisy.' The term includes all those pains of the side which are unconnected with pleuritic inflammation, whether arising from a rheumatic affection of the intercostal muscles, neuralgia in the same parts, or any other cause not evidently pleuritic.

PLEURONE'CTIDÆ, a family of fishes of the order Malacopterygii and section Subbrachiales. This family contains the Soles, Flounders, and Turbots, and some other fishes, all of which are readily distinguished by the flattened form of the body and in having both the eyes on one side. This want of symmetry in the form of the head, Cuvier states, is unique amongst vertebrate animals. The side of the body which is uppermost is always coloured, and might be mistaken for the back of the fish, whilst the opposite side is white. The two sides of the mouth are unequal, and it is uncommon to find the two pectoral fins equal; the dorsal and anal fins extend the whole length of the back and abdomen respectively; the ventrals appear like a continuation of the anal; the branchiostegous membrane has six rays.

The *Pleuronectidæ* are divided into the following genera:—

Genus 1. *Platessa*, in which the jaws are each furnished with a single row of obtuse teeth; on the pharyngeans are generally some teeth like paving-stones; the dorsal fin is only extended in front to a line with the eye, and leaves, as well as the anal, an interval between it and the caudal. The form of the body is rhomboidal, and the eyes are usually on the right side.

To this genus belongs the common Plaice (*Platessa vulgaris*, Cuv.), which is usually about a foot or rather more in length; of a brown colour above, spotted with red or orange; on the eye side of the head are some osseous tubercles; the lateral line is curved above the pectoral fin; the body is smooth, and the teeth are blunt and contiguous.

This fish is very abundant on various parts of the British coast, and is said sometimes to attain the weight of fifteen pounds.

The Flounder (*P. Flesus*), Dab (*P. Limanda*), and Lemon Dab (*P. microcephala*), are also examples of the genus *Platessa*.

Genus 2. *Hippoglossus*, Cuv. The species of this genus differ from the Plaices proper in having the body usually more elongated, and the jaws and pharyngeans armed with strong and pointed teeth.

The Holibut (*Hippoglossus vulgaris*, Flem.) is not uncommon on some parts of our coast, and is often exposed for sale in the London market. It is usually of large size. One specimen, taken in the Isle of Man, is said to have measured seven feet and a half in length. In the northern parts of Britain it is called the *Turbot:* the Holibut however is of a much longer form than the Turbot, and by no means equal to it in flavour.

Genus 3. *Rhombus*, Cuv. The species of this genus have the jaws and pharyngeans furnished with thickly set small pointed teeth; the dorsal fin commences immediately above the upper lip, and this fin, as well as the anal, extends very nearly to the tail. the eyes are generally on the left side.

The Turbot, Brill, Muller's Topknot, Bloch's Topknot, the Whiff, and the Scaldfish are British examples of the genus *Rhombus*.

The Turbot (*Rhombus maximus*, Cuv.), next to the Holibut, is one of the largest of the *Pleuronectidæ* found on our coast, and is the most highly esteemed for the table. The Turbot is of a short and broad form, and rather deeper than many of the flat fishes. Its prevailing colour is brown, and the whole of the coloured side is studded with hard and roundish tubercles; the lateral line is considerably arched above the pectoral fin, and thence runs straight to the tail: it is called in Scotland the Rawn Fleuk and Bannock Fleuk.

'On the coasts of Durham and Yorkshire,' says Mr. Yarrell, 'a considerable fishery of Turbot is carried on by the fishermen of Hartlepool and Scarborough with long lines.

'A large portion of the Turbot produced in the English market is taken on or near the various sand-banks between the long line of our eastern shore and the coast of Holland.'

The Brill (*Rhombus vulgaris*, Cuv.) is very similar to the Turbot in appearance, but inferior in flavour; it is common in the markets, and may at once be distinguished by its less broad form, the want of the osseous tubercles on the coloured side of the body, and the colouring, which is reddish or sandy brown varied with darker brown, and minutely spotted with white. It is moreover a smaller fish.

Genus 4. *Solea*, Cuv., contains the Soles, which are distinguished generally by their more elongated form and the blunt and rounded shape of the muzzle. The eyes, as well as the colouring, are on the right side; the teeth are small and confined to that side of the mouth which is opposed to the eyes; the dorsal fin commences in front of the line over the eyes, and extends, as well as the anal, to the tail-fin.

Cuvier separates as a subgenus from the Soles proper those species which have the pectoral fin on the side with the eyes very small, and that on the opposite side either rudimentary or altogether wanting. They are termed *Monochirus*.

The common Sole (*Solea vulgaris*, Cuv.) inhabits the sandy shore all round our coast, where it keeps to the bottom, and feeds upon small testaceous animals and the fry of other fishes; as they will not readily take bait, they are almost entirely caught by trawling. 'Eighty-six thousand bushels of Soles were received at Billingsgate-market only within the last twelve months.' (Yarrell's *British Fishes*, vol. ii., p. 25.)

Another species belonging to this section, called the Lemon Sole (*Solea pegusa*, Yarrell), is occasionally taken with the common species, from which it differs in being rather broader and of a yellowish colour.

Of the subgenus *Monochirus*, one species is found on the British coast, and is known by the names Variegated Sole, Red-backed Flounder, &c. (*M. linguatulus*). There are moreover certain Soles in which the pectoral fins are altogether wanting; they constitute the subgenus *Achirus* according to Lacépède.

PLEURO'PTERA, the name of a tribe of quadrupeds generally known as Flying Lemurs (*Galeopithecus* of Pallas; Flying Cats and Flying Foxes of voyagers). They are generally arranged under the order Carnassiers, and some authors place them in the division *Cheiroptera;* but they differ from the *Bats* inasmuch as the toes of their anterior extremities, which are all furnished with sharp claws, are not more elongated than those of the hind feet, so that the membrane which occupies the interval between the extremities to the sides of the tail can hardly operate in executing more than the functions of a parachute.

Dental formula:—Incisors, $\frac{4}{6}$; canines, $\frac{0-0}{0-0}$; molars, $\frac{6-6}{6-6} = 34$.

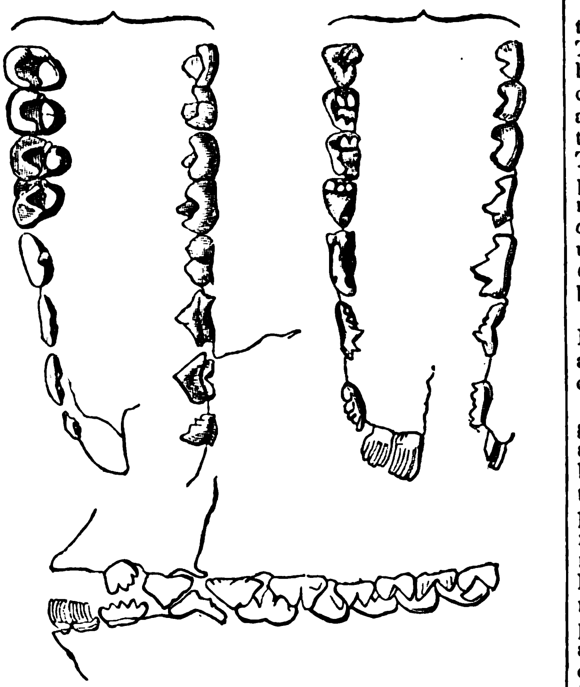
This is the formula given by M. Lesson; but Cuvier, in his *Règne Animal*, states that the canines are dentilated and short like the molars. He states that the two upper incisors are also dentilated and much separated from each other; and that the six lower ones are split into narrow strips like combs, a structure peculiar to this genus.

M. F. Cuvier's formula is similar to that of M. Lesson, and was probably copied by the latter. M. F. Cuvier describes the 12 molars in both jaws as consisting of four false molars and eight molars. He tells us that in the upper jaw, the intermaxillary bone, though very extensive, has no teeth in its anterior part, in the posterior part there are two on each side. The descending line in the upper part of the lower figure marks the extent of the intermaxillary bone.

The dentition, as it appears to Mr. Waterhouse, is as follows:—

Incisors $\frac{2-2}{4}$; canines $\frac{0-0}{1-1}$; false molars $\frac{2-2}{2-2}$; true molars $\frac{4-4}{4-4} = 34$.

The same author observes that the six foremost teeth in the lower jaw of the *Lemur* (four only of which are, in his opinion, incisors; for he agrees with Geoffroy in considering the remaining two as canines) together bear a remarkable resemblance to a single incisor of *Galeopithecus*. He compares the two canines to the outer *laminæ* of one of these incisors. Like one of these *laminæ*, the *Lemur's* canine is dilated immediately above the base, and has a longitudinal ridge on the upper side, whilst the incisors, like the intermediate *laminæ*, are grooved on the outer side near the apex. In their almost horizontal direction there is also a resemblance. In the number of teeth the *Galeopitheci* agree with the *Lemurs*, excepting that in the former the upper canines are wanting. In both these groups of animals the incisors of the lower jaw are, he observes, opposed to a toothless portion of the intermaxillaries. (*Zool. Trans.*, vol. ii., part 4.)



Teeth of Galeopithecus, one-third larger than nature. (F. Cuvier.)

Geographical Distribution of the Genus, Habits, &c.—Cuvier and others state that the *Galeopitheci* live on trees in the islands of the Indian Archipelago, and there pursue insects, and perhaps birds, as their prey: judging from the detrition of the teeth with age, he thinks that they must also feed on fruits. They have a very large cæcum. In their teeth they present many analogies to the *Lemuridæ*.

Mr. Gray makes the *Galeopithecidæ* the fourth family of the (quadrupedoid) *Primates*, and places it between the *Lemuridæ* and *Vespertilionidæ*. (*Outline, &c.*, in *Ann. of Philosophy*, 1825.)

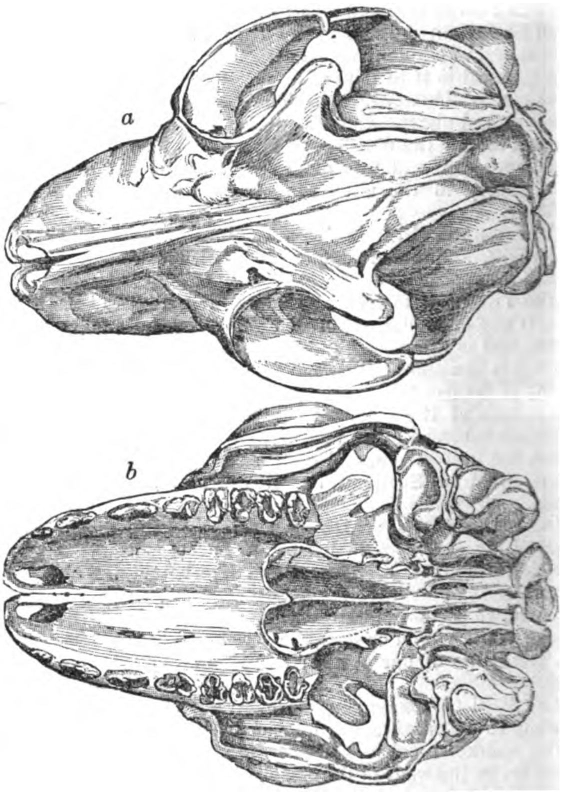
Speaking of the *Galeopithecus* of Pallas, Mr. Swainson observes: 'To give its most striking character in a few words, it is a lemur, with the limbs connected by a bat-like membrane, or, in other words, surrounded by a thin skin which they support, as the framework of an umbrella supports its covering. By this singular structure, the animal is supported in the air; yet without the power, like the bats, of sustaining a continued flight. Linnæus places this remarkable genus with the lemurs, while every one must perceive its intimate affinity to the bats; like them also, these bat-lemurs are nocturnal and insectivorous; the mammæ are pectoral; and they sleep suspended by their hind legs with their heads downward. M. Geoffroy St. Hilaire therefore justly considers them as the form by which the lemurs and bats are connected; while their greater resemblance to the former induces us to consider *Galeopithecus* as one of the aberrant types of the *Lemuridæ*,' among which Mr. Swainson arranges the genus, in the third part of his volume, between *Aötes* and *Cheirogaleus*. (*Natural History and Classification of Quadrupeds*, 1835.)

Three species have been recorded: 1, *Galeopithecus rufus*, Geoff., Audeb. (*Lemur volans*, Linn.); 2, *Galeopitherus variegatus*, Cuv., Geoff.; 3, *Galeopithecus Ternatensis*, Geoff.: but the general opinion seems to have been that one only, the *Lemur volans* of Linnæus, had been satisfactorily made out. In October, 1838, some specimens of Flying Lemurs were upon the table at a meeting of the Zoological Society of London, and in reference to them Mr. Waterhouse pointed out certain characters which appeared to him to indicate the existence of two species in those specimens.

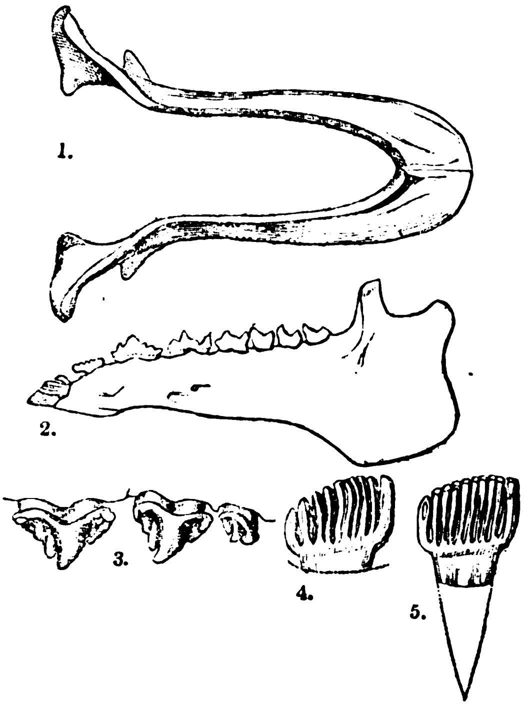
He remarked that in systematic works three species of the genus *Galeopithecus* are described, founded upon differences of size and colour: as regards the latter character, he had never seen two specimens which precisely agreed; and, with respect to size, the dimensions given of two out of the three species are, he observed, evidently taken from extremely young animals. Mr. Waterhouse then proceeded to distinguish the two species on the table, and proposed for them the specific names of *Temminckii* and *Philippinensis*.

The first and larger species measured about two feet in total length, and its skull was 2 inches 11½ lines in length. The anterior incisor of the upper jaw is broad, and divided by two notches into three distinct lobes; the next incisor on each side has its anterior and posterior margins notched; and the first molar (or the tooth which occupies the situation of the canine) has its posterior edge distinctly notched. This tooth is separated by a narrow space, anteriorly and posteriorly, from the second incisor in front and the second molar behind; the temporal ridges converge towards the *occiput*, near which however, he observed, they are separated usually by a space of about four lines. This is probably the *Galeopithecus volans* of authors; but the identity cannot be said to be certain.

The second species, *G. Philippinensis*, was described by Mr. Waterhouse as being usually about 20 inches in length, and its skull as measuring 2 inches 7 lines in length. He observed that this species may be distinguished from *G. Temminckii* by the proportionately larger ears and the greater length of the hands. The skull too he described as narrower in proportion to its length, the muzzle as broader and more obtuse, and the orbit as smaller. The temporal ridges, he remarked, generally meet near the occiput, or are separated by a very narrow space. The anterior incisor of the upper jaw is narrow, and has but one notch; the next incisor on each side is considerably larger, longer, and stronger than in *G. Temminckii*, and differs moreover in having its edges even—the same remark applies to the first false molar. In this species the incisors and molars form a continuous series, each tooth being in contact with that which precedes and that which is behind it. But Mr. Waterhouse concluded by observing that the most important difference perhaps which exists between the two species in question consists in the much larger size of the molar teeth in the smaller skull, the five posterior molars occupying a space of 10 lines in length, whereas in *G. Temminckii*, a much larger animal, the same teeth only occupy 9 lines. Several minor points of distinction existed besides those here mentioned. (*Zool. Proc.*, 1839; and see further *Zool. Trans.*, vol. ii., p. 335.)



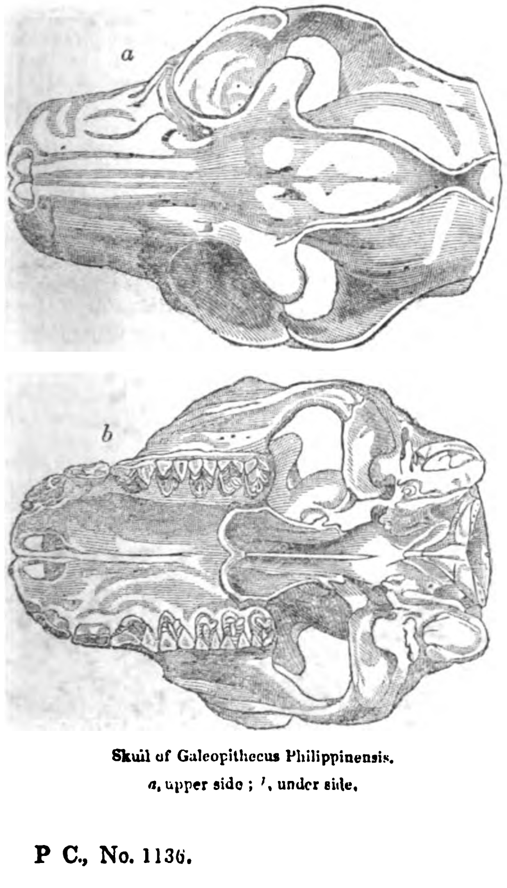
Skull of Galeopithecus Temminckii.
a, seen from above; *b*, seen from below. (Waterhouse, *Zool. Trans.*)



Lower jaw and teeth of Galeopithecus Temminckii.

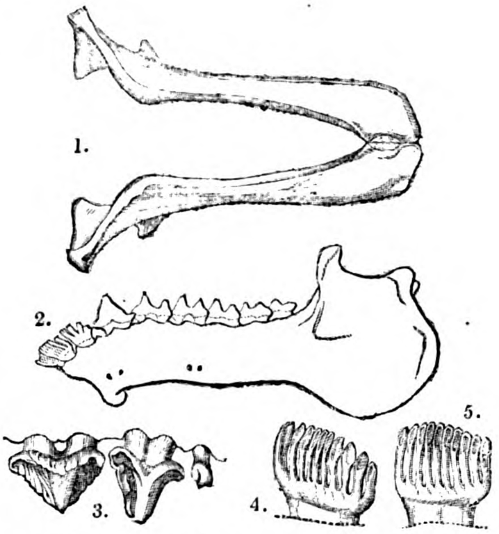
1, under side of the lower jaw: 2. side view of the same; 3, the three foremost teeth on either side of the upper jaw; 4, 5, outer and inner incisors of the lower jaw. (Waterhouse, *Zool. Trans.*)

N.B. Mr. Waterhouse remarks that the two first of the three foremost teeth of the upper jaw, commencing with the smallest tooth, are situated in the intermaxillary bone, and are therefore incisors. He adds that it is worthy of observation, that the posterior of these two teeth (on each side) *has a double fang.*



Skull of Galeopithecus Philippinensis.

a, upper side; b, under side.



Lower jaw and teeth of Galeopithecus Philippinensis.

1, under side of the lower jaw; 2, side view of the same; 3, the three foremost teeth, upper jaw; 4, 5, outer and inner incisors of lower jaw. (Waterhouse, *Zool. Trans.*)

Galeopithecus Temminckii.

PLEURORHYNCHUS, the generic name assigned by Professor Phillips to the singular fossil conchifers known, by Mr. Sowerby's excellent figures in the 'Mineral Concology of Great Britain,' as Cardium hibernicum, C. alæforme, &c. There are six species in the carboniferous limestone of the North of England. (*Geol. of Yorkshire*, vol. 2.) None are mentioned by Mr. Murchison in the Silurian rocks; but one or two occur in the old limestones of the Eifel, Westphalia, and South Devon.

The principal character of the genus is the lateral production of the valves from beneath their incurved beaks into a spinelike or conical umbo (πλευρα, 'side;' ῥυγχος, 'beak').

PLEURO'TOMA. [SIPHONOSTOMATA.]

PLEXAURA, a subdivision of the Linnæan genus Gorgonia. [ZOOPHYTARIA.]

PLEYEL, IGNACE, or IGNAZ, a composer in great repute towards the close of the last century, was born in 1757, at Rupperstahl near Vienna. It may not be unworthy of remark that he was the twenty-fourth child of Martin Pleyel, a schoolmaster, and of a lady of noble family, who incurred the resentment of her parents by her marriage, and was disinherited. In giving birth to the subject of this notice she died, and the widower having again entered into the matrimonial state, had fourteen children by his second wife, and lived to attain his ninety-ninth year. Ignace was, according to the Austrian custom, initiated in Latin and music at a very early age. When sufficiently advanced in the latter, he had Vanhall for a master, and subsequently Haydn; but the last was too great a genius to be a good teacher, and the student acquired more knowledge of his art during an extensive tour which he soon made in Italy, then the land of song, by hearing the best works of the celebrated composers, and more taste by listening to the distinguished performers of that country, than by all the lessons he had received in Vienna.

In 1783, Pleyel was appointed *Maître-de-Chapelle* of Strasburg cathedral, and there composed many masses and motets, the whole of which were destroyed in a great fire shortly after they were written. During the next ten years he produced nearly all those works which carried his name into every city in Europe. In 1791 he visited London, on the invitation of the managers of *The Professional Concert*, who engaged him as a kind of rival to Haydn (whose services had been secured by Salomon for his concerts), and composed for them three symphonies, for which and his personal assistance he received a large sum, which he invested in the purchase of an estate near Strasburg. [CONCERT; HAYDN.] In 1793, during the phrenzy of the French revolution, he became a suspected person, and, having been several times denounced, at length deemed it prudent to fly, but was pursued and taken. He then pleaded his acquiescence in the new order of things; nevertheless, as a proof of his sincerity, he was required to set a kind of drama for the anniversary of the 10th of August. This he accomplished under the surveillance of two gendarmes, and saved his life. Thoroughly alarmed however at violences which were even more indiscriminate and atrocious in some of the provinces than in the capital, he sold his property, went to Paris, and entered into a widely extended commercial speculation as publisher of music and manufacturer of piano-fortes. This proved successful, and after a long, active, laborious career, he retired to an estate near Paris purchased by the fruits of his talents and industry, and indulged his taste for agriculture. But the revolution of 1830 excited in him fresh though unnecessary alarm, and violently agitated a frame not naturally strong. His health failed, and, after much anxiety and suffering, he died, in November, 1831. He left one son, who inherited some portion of his father's genius, but soon abandoned music as an art, and, following his parent's steps, pursued it very prosperously as a trade.

Pleyel, in the height of his popularity, was over-valued, and afterwards, when the tide of fashion turned against him, was under-rated. Through nearly all his compositions a stream of agreeable melody flows; they are marked by a style peculiarly his own, generally light, sometimes very trivial, but occasionally bold and vigorous. A few of his quartets possess much beauty, and when the prejudices against him are subdued by time, these, as well as his admirable Concertante, will be revived. The same act of justice will perhaps, at no distant period, be done to his Sonatas dedicated to the queen of England, as well as to those with Scottish airs, the comparative simplicity of which has for the present caused them to be thrown aside. Had posthumous fame been more his aim than immediate profit, Pleyel had that within him which might have secured the attainment of a considerable share of lasting celebrity.

PLICA POLO'NICA is the name given to a disease which is chiefly remarkable for the sticking together and matting of the hair, and which is peculiarly frequent in Poland: a few examples of it have been met with in Tartary, among the lower orders of the Russians, and in Hungary, and fewer still in Switzerland and France.

The disease chiefly affects the scalp; the hair grows to an unusual length, is matted together by a sticky and most offensively-smelling secretion, and is commonly infested with vermin. Indeed, the symptoms of the disease, as far as the hair is concerned, are only those which would result from excessive neglect of cleanliness; and hence many who have seen numerous cases in Poland, believe that they are only produced by the dirty habits of those affected, who, it is well known, if the disease do not spontaneously make its appearance, spare no pains to produce it. So great is the prejudice in favour of Plica entertained by the lower order of Poles, who regard it as affording a certain security from all other sickness and misfortunes, that they will through their whole lives endure the inconvenience and misery of carrying about huge masses of filthy stinking hair many feet in length, rather than submit to the removal of it, which is necessary for their relief.

There is sufficient evidence however that in many cases the Plica is not merely the result of uncleanliness; a kind which has been called false plica is undoubtedly often so produced; but in many instances the secretion of the viscid material from the scalp is preceded by the general symptoms of slight fever, headache, and increased sensibility of the skin. The scalp is extremely tender, and bleeds on the slightest injury, and the least pulling of the hair excites exquisite pain. When the secretion commences, these symptoms commonly subside. The only treatment which is known to be constantly beneficial is the removal of the hair, and strict cleanliness; other means must be decided in each case by the general state of the patient's health. The popular notion entertained in Poland, that dangerous diseases will follow the cutting of the hair, is entirely without foundation.

PLICA'TULA. [SPONDYLIDÆ.]

PLICIPENNES, according to Latreille, the third section into which the Neuropterous insects are divided. The insects belonging to this section are well known to anglers by the name of Caddis-fly, and in the larva state they are called caddis-worm or cadew-worm. They constitute the genus *Phrygania* of De Geer, and have been raised to the rank of an order by Messrs. Kirby and Spence and Dr. Leach, being the order *Trichoptera* of their systems.

The *Phryganiæ*, or Caddis-flies, are distinguished from other Neuropterous insects by the absence of mandibles, and in the structure of their mouth; in fact they evince an approach to the Lepidopterous insects as well as in some other characters; the wings are semitransparent, and when closed meet at an angle, like the roof of a house; they are usually hairy, hence the name Trichoptera; the posterior wings are longitudinally folded, and usually broader than the anterior pair; the head is small and furnished with two simple eyes, situated on the vertex, besides the ordinary compound eyes; the antennæ are very long and thread-like, and composed of very numerous indistinct joints; the palpi are four in number, the maxillary have often five joints in the females, and the labial palpi are three-jointed.

The larva, or Caddis-worm, always lives in the water, and encloses itself in a cylindrical case, open at both ends, and formed of pieces of stick, small shells, and various other substances, which the insect joins together by a silken web.

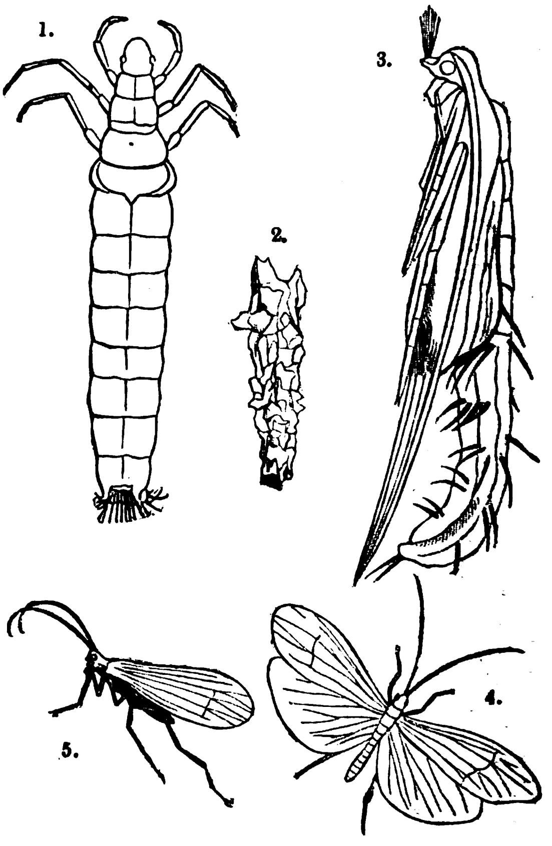


Fig. 1, Larva of a species of Phrygania, magnified; 2, case inhabited by the larva; 3, the pupa, magnified; 4, the perfect insect with the wings expanded; 5, ditto, with the wings in the ordinary position when the insect is at rest.

It never quits this case, but when it wishes to move it protrudes the fore part of the body, which is furnished with six tolerably long legs, and crawls about with the case attached to the hinder part, it being held by means of two hooks situated on the last segment of the abdomen. The form of the larva is nearly cylindrical, but slightly compressed; the head and first three segments of the body (which in fact constitute the thorax) are coriaceous, the remaining segments are soft. When about to change into the pupa state, the larva fixes its tube to some substance in the water, and closes the ends. The transformation is what is termed complete, the pupa resembling the perfect insect, except in having the wings imperfectly developed, and also in having two hooks on the fore part of the head, by means of which it makes its escape from the case, that it may swim to some dry situation when about to assume the perfect state.

The *Phryganiæ* are very numerous, and M. Pictet states that they abound more in the northern than in the southern parts of Europe. Their larvæ being always aquatic, they are generally found near the water; they fly chiefly in the evening, and are not unfrequently seen in immense numbers. The author just quoted, M. Pictet, has published a quarto volume,* with numerous plates, in which, after giving a detailed account of the anatomy and habits of these insects, he traces very many of them through all their stages. In this work, which is one of the most perfect monographs ever published, the *Phryganiæ* are divided into eight genera, as follows:—

Genus 1, *Phrygania* proper, distinguished by the superior wings, having some transverse nervures near the bifurcation of the principal nervures, the posterior wings folded; the antennæ setaceous, and equal in length to the wings; maxillary palpi but slightly pubescent, those in the males three-jointed, and those of the female having five joints; the terminal joint is ovate, and shorter than the two preceding taken together. Of this genus upwards of thirty species are known in Europe, some of which are the largest of the Phryganidæ.

Genus 2. *Mystacida*, Latreille. Anterior wings straight and elongated, having a few transverse nervures; posterior wings much folded; antennæ setaceous and slender, longer than the wings; maxillary palpi five-jointed in both sexes, long and pubescent.

Genus 3. *Trichostoma*, Pictet. Anterior wings short, without transverse nervures; posterior wings but slightly folded; antennæ comparatively thick and short, the basal joint very hairy; maxillary palpi three-jointed in the male, the terminal joint stout and more densely clothed with hair on the opical portion than at the base.

Genus 4. *Sericostoma*, Latreille. Anterior wings without transverse nervures; posterior small, and but slightly folded; antennæ stout and short, and having the basal joint long and thick; the maxillary palpi in the male shaped like the bowl of a spoon, and uniting to form a rounded muzzle.

The larvæ of the species of this genus inhabit a case which approaches to a conical form, and is more or less curved; it is composed of pieces of sand and small stones joined together. The perfect insect is slow in its movements.

Genus 5. *Rhyacophila*, Pictet. Anterior wings without transverse nervures; posterior wings straight, of the same form as the anterior pair, and almost destitute of folds; antennæ moderate, maxillary palpi five-jointed in both sexes, the second joint almost as short as the first, and the terminal joint ovate; abdomen often terminated by coriaceous appendages.

This genus contains many species, all of which are of small size.

Genus 6. *Hydropsyche*, Pictet. Anterior wings without transverse nervures; posterior wings folded, antennæ slender, maxillary palpi five-jointed in both sexes, the terminal joint almost equal in length to the other joints taken together, and very slender.

This is also a numerous group. The larvæ live almost always in running waters. The perfect insect is often spotted.

Genus 7. *Psychomyia*, Latreille. Anterior wings straight, pointed, and without transverse nervures; posterior wings resembling the anterior, and not folded; antennæ moderate, maxillary palpi five-jointed in both sexes, the terminal joint long and slender.

Genus 8. *Hydroptila*, Dalman. Anterior wings attenuated and pointed, very hairy, and with the nervures indistinct; posterior wings resembling the anterior, not folded, antennæ short and filiform, maxillary palpi five-jointed in both sexes, the terminal joint ovate.

PLI'NIUS VALERIA'NUS, a name mentioned in a Latin inscription found at Como (Gruter, i. 635), and given to the author of a work entitled 'Medicinæ Plinianæ Libri Quinque.' Nothing is known of his life, but the work is supposed to have been written about the fourth century A.D. It is a book on domestic medicine, compiled from Pliny the Elder, Dioscorides, Galen, and others, and is not of much value. The first three books are taken up with a list of diseases, beginning with the head, and descending to the feet, and contain an account of a great number of medicines, partly taken from the elder Pliny and partly from later writers. The fourth book treats of the properties of plants according to their names, and is in a great measure taken from Galen. The fifth book, which is almost entirely extracted from Alexander Trallianus, is upon diet as accommodated to different diseases. There is a little book by Just. Godofr. Günz, entitled 'De Auctore Operis de Re Medicâ, vulgo Plinio Valeriano ascripti,' Lips., 1736, 4to., in which, with much learning and ingenuity (but, in Haller's opinion, unsuccessfully), he tries to prove that the work in question was written by a Christian physician named Siburius, who is mentioned in the preface to Marcellus Empiricus. It was first published at Rome, 1509, fol., by Th. Pighinuccius: it was reprinted (and, according to Haller (*Biblioth. Med. Pract.*), much more accurately), Bonon., 1516, fol. It is also to be found in some of the collections of the old medical writers, namely, in that of Torinus (*Thorer*), Basil., 1528, fol.; and in the Aldine, Venet., 1547, fol.

PLINLIMMON. [CARDIGANSHIRE; MONMOUTHSHIRE.]

PLINTH. [COLUMN; CIVIL ARCHITECTURE.]

PLINY THE ELDER. CAIUS PLINIUS SECUNDUS was born, as is commonly supposed, A.D. 23. The place of his birth is very uncertain, and has been the subject of much learned controversy. The antient writer of his life, ascribed to Suetonius, and after him St. Jerome (*in Chron.*), call him a native of Como (*Novocomensis*); while in an old anonymous life he is said to have been born at Verona, and in the preface to his 'Natural History' he calls Catullus (who was certainly born there) his fellow-countryman (*conterraneum*). A full account of the arguments on both sides is given by Rezzonico, in his 'Disquisitiones Plinianæ,' who is himself inclined to give the honour to Como. Very little is known of the events of Pliny's public life; we are merely told that he was of a noble family, and after distinguishing himself in the field, and filling the office of augur at Rome, was appointed procurator of Spain. These employments however he did not suffer to hinder his studies; and his manner of life, as it is described by his nephew (Plin., *Epist.*, iii. 5), exhibits a degree of industry and perseverance scarcely to be paralleled. In summer he always began his studies as soon as it was light; in winter, generally at one in the morning, but never later than two, and often at midnight. No man ever spent less time in bed; and sometimes he would, without retiring from his books, indulge in a short sleep, and then pursue his studies. Before day-break, it was his custom to wait upon Vespasian, who likewise chose that season to transact business; and when he had finished the affairs which the emperor committed to his charge, he returned home again to his studies. After a slender repast at noon, he would frequently, in the summer, if he was disengaged from business, recline in the sun, during which time some author was read to him, from which he made extracts and observations. This was his constant method, whatever book he read; for it was a maxim of his, that 'no book was so bad but something might be learned from it.' When this was over, he generally went into the cold bath, after which he took a slight refreshment of food and rest; and then, as if it had been a new day, resumed his studies till supper-time, when a book was again read to him, upon which he would make some remarks as they went on. His nephew mentions a singular instance (*Epist.*, iii. 5) to show how parsimonious he was of his time, and how eager after knowledge. His reader having pronounced a word wrong, some one at the table made him repeat it; upon which, Pliny asked that person if he understood it, and when he acknowledged that he did, 'Why then,' said he, 'would you make him go back again? We have lost by this interruption above ten lines.' In summer he always rose from supper by day-light; and in winter, as soon as it was dark. Such was his way of life amidst the noise and hurry of the town; but in the country his whole time was devoted to study without intermission, excepting only when he slept, and when he bathed, that is, was actually in the bath; for during the operation of rubbing and wiping, he was employed either in hearing some book read to him or in dictating himself. In his journeys he lost no time from his studies, his mind at those seasons being disengaged from all other thoughts, and a secretary or amanuensis constantly attended him in his chariot; and that he might suffer the less interruption to his studies, instead of walking, he always used a carriage in Rome. By this extraordinary application, he found leisure to write a great number of volumes.

---

* 'Recherches pour servir a l'Histoire et à l'Anatomie des Phryganides,' Geneva, 1834.

The circumstances of his death, like his manner of living, were very singular, and are also described at large by the elegant pen of his nephew. He was at that time, with a fleet under his command, at Misenum, in the Gulf of Naples, his sister and her son the younger Pliny being with him. On the 24th of August, A.D. 79, about one in the afternoon, his sister desired him to observe a cloud of a very unusual size and shape. He was in his study; but immediately arose, and went out upon an eminence to view it more distinctly. It was not at that distance discernible from what mountain this cloud issued, but it was found afterwards to ascend from Mount Vesuvius. Its figure resembled that of a pine-tree; for it shot up to a great height in the form of a trunk, which extended itself at top into a sort of branches; and it appeared sometimes bright, and sometimes dark and spotted, as it was either more or less impregnated with earth and cinders. This was a noble phenomenon for the philosophic Pliny, who immediately ordered a light vessel to be got ready; but as he was coming out of the house with his tablets for his observations, the mariners belonging to the galleys stationed at Retina earnestly intreated him to come to their assistance, since that port being situated at the foot of Mount Vesuvius, there was no way for them to escape but by sea. He therefore ordered the galleys to be put to sea, and went himself on board, with the intention of assisting not only Retina, but several other towns situated upon that beautiful coast. He steered directly to the point of danger, from which others were flying with the utmost terror, and with so much calmness and presence of mind, as to be able to make and dictate his observations upon the motion and figure of that dreadful scene. He went so near to the mountain, that the cinders, which grew thicker and hotter the nearer he approached, fell into the ships, together with pumice-stones and black pieces of burning rock: they were likewise in danger not only of being aground by the sudden retreat of the sea, but also from the vast fragments which rolled down from the mountain, and obstructed all the shore. Here he stopped to consider whether he should return, to which the pilot advising him, 'Fortune,' says he, 'befriends the brave; carry me to Pomponianus.' Pomponianus was then at Stabiæ, a town separated by a gulf which the sea, after several windings, forms upon that shore. He found him in the greatest consternation, but exhorted him to keep up his spirits; and the more to dissipate his fears, he ordered, with an air of unconcern, the baths to be got ready. After having bathed, he sat down to supper with apparent cheerfulness. In the meanwhile the eruption from Vesuvius flamed out in several places with much violence, which the darkness of the night contributed to render still more visible and dreadful. Pliny, to soothe the apprehensions of his friend, assured him it was only the burning of the villages which the country-people had abandoned to the flames: after this he retired, and had some sleep. The court which led to his apartment being in the meantime almost filled with stones and ashes, if he had continued there any longer it would have been impossible for him to have made his way out; it was therefore thought proper to awaken him. He got up, and went to Pomponianus and the rest of the company, who were not sufficiently unconcerned to think of going to bed. They consulted together whether it would be most prudent to trust to the houses, which now shook from side to side with frequent and violent rockings, or to fly to the open fields, where the calcined stones and cinders, though light indeed, yet fell in large showers and threatened destruction. In this distress they resolved for the fields, as the less dangerous situation of the two; and went out, having pillows tied upon their heads with napkins, which was all their defence against the storms of stones that fell around them. It was now day everywhere else; but there a deeper darkness prevailed than in the most obscure night, which however was in some degree dissipated by torches and other lights of various kinds. They thought proper to go down farther upon the shore, to observe if they might safely put out to sea; but they found the waves still running extremely high and boisterous. There Pliny, taking a draught or two of water, threw himself down upon a cloth that was spread for him; when immediately the flames, and a strong smell of sulphur which was the forerunner of them, dispersed the rest of the company, and obliged him to arise. He raised himself, with the assistance of two of his servants (for he was corpulent), and instantly fell down dead, suffocated, as his nephew conjectures, by some gross and noxious vapour; for he had always weak lungs, and was frequently subject to a difficulty of breathing. As soon as it was light again, which was not till the third day after, his body was found entire, and without any marks of violence upon it, exactly in the same posture that he fell, and looking more like a man asleep than dead.

Such is the interesting account given by the younger Pliny, in a letter to Tacitus (*Epist.*, vi. 16), of the death of this remarkable man. The titles of several of his works are given by his nephew (*Epist.*, iii. 5); of these the only one that is still extant is his 'Natural History,' which may well be called 'a work of great compass and erudition, and as varied as nature herself.' (*Ibid.*) To give anything like a complete critical analysis of this work would require the immense and multifarious learning of Pliny himself, and a thorough knowledge not only of all that the antients have written on the same subjects, but also of all the improvements and discoveries of modern times. Accordingly in the French translation, lately published, the assistance of a great number of scientific men has been secured, each of whom has laboured to illustrate Pliny's opinions on his own particular branch of knowledge. The work consists of thirty-seven books, all of which are still extant, though the text is in many places in a very corrupt state, and several passages are quite lost. The first book is a table of the contents of the other thirty-six; the second treats of the world, the elements, the stars, the winds, &c.; the third, fourth, fifth, and sixth contain a geographical account of the whole of the then known world; the seventh treats of the generation and organization of man, the most remarkable characters that have ever lived, and the most useful inventions; the eighth, ninth, tenth, and eleventh contain a system of zoology, and treat of beasts, fishes, birds, and insects, and of human and comparative anatomy; sixteen books, from the twelfth to the twenty-seventh, are given up to botany, and give an account of trees, herbs, fruit, corn, &c., and the medicines which they furnish; five books, from the twenty-eighth to the thirty-second, treat of medicines derived from different animals; the thirty-third and thirty-fourth, of different kinds of metals, &c.; the thirty-fifth, of colours and painting; the thirty-sixth, of stones and sculpture; and the thirty-seventh, of different kinds of gems, &c.

This will give some idea of the miscellaneous nature of the contents of this extraordinary work, and if the judgment of the writer had been equal to his industry and learning, it might well have been considered as one of the greatest monuments of human ability. However, the contrary is notoriously the case, so that (as Sir Thomas Brown quaintly observes, in his 'Vulgar Errors') 'there is scarce a popular error passant in our days which is not either directly expressed or diductively contained in this work.' It may however be more satisfactory to hear the opinions of two men, perhaps the most able of any naturalists of modern times to judge of his merits and his defects, Buffon and Cuvier. 'His work,' says the former, 'is on a much larger scale than that of Aristotle, perhaps indeed *too* vast. He wished to embrace everything, and seems to have measured nature, and found her too small for his genius. His "Natural History" comprehends (besides the history of animals, plants, and minerals) that of the heavens and the earth, medicine, commerce, navigation, the history of the liberal and mechanical arts, the origin of customs, and in short, all the natural sciences, and all human arts; and what is most astonishing is, that in each department he is equally great. The loftiness of his ideas and the nobleness of his style enhance still more his profound learning. He not only knew all that in his age could be known, but he had that facility of thinking on a grand scale which multiplies science; he had that nicety of reflection on which depends elegance and taste; and he communicates to his readers a certain freedom of spirit and boldness of thought, which is the germ of philosophy. His work, no less varied than nature herself, always paints her in the brightest colours. It may be called a mere compilation of all that had been written before him, a copy of all that was excellent and useful to be known; but still this copy has such grand features, this compilation contains things put together in so novel a manner, that it is preferable to the greater part of original works which treat on the same subjects.' (Buffon, *Discours Premier sur l'Hist. Nat.*)

The character given by Cuvier (*Biogr. Univers.*, tome xxxv.) is not so favourable, but is more correct. 'Pliny's great work,' says he, 'is at the same time one of the most precious monuments left us by antiquity, and a proof of the astonishing learning of a warrior and a statesman. In order justly to appreciate this vast and celebrated composition, it is necessary to consider the plan, the facts, and the style. The plan is immense,' &c. &c. 'It was impossible but that the author, in treating of this prodigious number of objects, however rapidly, should record a multitude of remarkable facts, which are to us the more valuable, as he is the only extant author who mentions them. Unhappily the way in which he has collected and arranged them causes them to lose much of their value by the mixture of truth and falsehood which is met with in almost equal proportions, and especially by the difficulty (and in most cases the impossibility) of recognising the precise creatures that he means to describe. Pliny was not an observer, like Aristotle; still less was he a man of genius, capable, like that great philosopher, of seizing the laws and relations which have guided nature in her productions. In general he is only a compiler, and indeed for the most part a compiler who has not himself any idea of the subjects on which he collects the testimonies of others, and therefore cannot appreciate the truth of these testimonies, nor even always understand what they mean. In short he is an author devoid of criticism, who, after having spent a great deal of time in making extracts, has ranged them under certain chapters, to which he has added reflections that have no reference to science properly so called, but display alternately either the most superstitious credulity, or the declamations of a discontented philosophy, which finds fault continually with mankind, with nature, and with the gods themselves.'—'A comparison of his extracts with such of the original authors as are still extant, and especially with Aristotle, shows us that Pliny was far from selecting either what was most important or most exact. In general he prefers whatever is singular and marvellous, whatever helps him in establishing the contrasts he so much delights in, or the reproaches he is so fond of uttering against Providence. It is true that he does not give the same degree of faith to everything that he mentions, but it is quite by chance that he believes or doubts; and it is by no means the most childish stories that always provoke his incredulity.'—'Another great fault in Pliny is that he does not always give the true sense of the authors that he translates, especially in the designation of different species of animals; and though we have so few materials remaining to enable us to judge of this kind of error with any degree of certainty, it is easy to prove that in several instances he has mistranslated the names of the animals mentioned by Aristotle.'—'It must then be confessed that, as far as his facts are concerned, the only part of his work which has any real interest for us in the present day is that which relates to the manners and customs of the antients, and to their proficiency in different arts, besides some historical and geographical details, which are to be found nowhere else.'—'With respect to his style, wherever he introduces general ideas or philosophical views, his language assumes an energy and vivacity, and his thoughts acquire an unexpected boldness, which makes some amends for his dry enumerations, and excuses him, in the opinion of many of his readers, for the deficiencies of his scientific information. He is perhaps too fond of point, and contrast, and emphasis; and there is in some places an obscurity, which results less from the nature of his subject than from a desire of expressing himself with a pregnant brevity and conciseness; but he is always grave and noble, and everywhere shows a love of justice and respect for virtue, a horror of the cruelty and meanness of which he had before his eyes such terrible examples, and a contempt for the unbridled luxury which had in his time so deeply corrupted the Roman people. In these respects he cannot be too much commended; and in spite of the defects which we cannot but recognise in him when we consider him as a naturalist, we must nevertheless allow that of all the authors who wrote after the Augustan age, he deserves to be regarded as one of the most valuable and most worthy to be ranked among the classics. It must however be confessed,' adds Cuvier, 'that he was almost an atheist, or at least that he acknowledged no other god than the World; and few philosophers have set forth the system of pantheism with more copiousness and energy than he has done in the second book of his "Natural History."'

Not the least important part of Pliny's work is his compendious history of the arts amongst the Greeks, in books xxxiv., xxxv., and xxxvi.; for though so often minute and circumstantial in his details of unimportant matters, and often negligent and careless about subjects of the highest interest, Pliny's account is upon the whole clear and succinct, and evidently contains many extracts from the writings of antient artists themselves.

The errors that we have to reproach him with are either unimportant inaccuracies inseparably connected with so great an undertaking as his 'Natural History,' or some few misconceptions owing to his want of a practical acquaintance with the arts, and which may be easily remedied by an artist. At the same time it cannot be denied that he is frequently credulous and his matter irrelevant, and his accounts are occasionally such a confusion of tradition and legend, that it is almost impossible to distinguish what is authentic from what is fabulous; such is his account of the origin of the imitative arts (xxxv. 12, 43). It is also evident that he frequently did not clearly understand what he has endeavoured to convey to others, and the consequence is, that he is sometimes unintelligible; yet this may be partly owing to the corrupt state of his text. He also lavishes encomiums upon the most trivial objects and examples of purely mechanical excellence, and passes cursorily over the greatest works, as the paintings of Polygnotus at Delphi (xxxv. 9, 35) and the Jupiter of Phidias at Olympia (xxxiv. 8, 19; xxxvi. 5, 4). Of the Laocoon however he says (xxxvi. 5, 4), that as a work of art it was superior to any production either of painter or sculptor; and with him the art of Apelles is synonymous with unrivalled excellence.

He commences his historical sketch, but more particularly that of painting, from the time of Polygnotus and Phidias; everything that took place before that time he very summarily terms the *incunabula*, or first efforts of art. His immediate authorities probably gave him no satisfactory account of an earlier period. Concerning this period however he has given us many valuable though unconnected remarks. Yet, when we consider the original sources that he appears to have consulted—the writings of antient painters and sculptors, the works of Apelles, Euphranor, Antigonus, Xenocrates, Pasiteles, and Menaechmus, all of which are mentioned by Pliny himself (and there were many others that he might have consulted) (Junius, *De Pic. Vet.*, ii. 3), the volumes of Melanthius, Pamphilus, Protogenes, and others—we cannot help feeling surprise that he has given us so little, and we are induced to conclude, with Fuseli, 'that he was more desirous of knowing much than of knowing well.' However, out of about one hundred artists of great celebrity, of whom more than the third were painters, the rest sculptors, statuaries, and workers of gems, &c., and more than twice that number of artists of less note, whose names have been handed down to us, Pliny has scarcely omitted one name of importance, but has on the other hand preserved notices of the works of many artists of whom we have no mention whatever in any other antient writer. In his dates he seldom errs.

The following is the opinion of Flaxman upon this part of Pliny's 'History,' perhaps in such matters the greatest critic of modern times. He says the whole is 'arranged with attention to the several improvements in chronological order, with such perspicuity and comprehension, that whenever, from the brevity of the work, we do not find all we wish for—yet, by attending to the information prior and subsequent, we shall easily be enabled to supply the defect from other writings or monuments of antiquity.'

The 'Geography' of Pliny is an important part of his 'Natural History,' but the same general remarks will apply to it that apply to the whole compilation; it is the work of a man who had abundant materials before him, but either knew not how to use them or did not take pains enough. This geographical sketch, which comprehended the then known world, is much too brief to be perspicuous; so much is crowded into a narrow compass, that it is often almost a bare catalogue of names, and if we had no other guides, it would continually mislead us. Pliny's description of what he calls Græcia, which commences with Attica, is a good example of his careless and confused compilation; and yet he has, even in his 'Geography,' preserved many curious facts, and he must have often had access to excellent materials. As examples of this we may mention his remarks on the Niger [NIGER]; his observation (vi. 17) that the word 'Imaus' (Himalaya) in the native language signifies 'snowy,' which is quite correct; his remarks on Taprobane (Ceylon), and generally his remarks on India; his account of the Atlas, founded on the authority of Suetonius Paulinus; and other things of the like kind, which render this part of his compilation valuable for incidental facts, thought it is of no value as a systematic work.

The number of editions that have been published of his work is immense, and more than twenty appeared before the end of the fifteenth century. However, only the most curious and the most valuable can here be noticed. The first edition was published at Venice, 1469, fol., by Joannes de Spira. There is an ample account of it in Schweiger's 'Handbuch der Class. Bibliogr.,' and in Dibdin's 'Greek and Latin Classics,' who says that 'the elegance of the Roman type, the regularity of the press-work, the strength and tint of the paper, the breadth of the margin, and the quantity of text which each page exhibits, afford altogether a perfect picture of antient typography.' With respect to its critical worth the Bipont editors thus observe, from Rezzonico:—'Vitiose expressa multa, sed tamen multa meliora quàm in aliis editionibus; unde ad textum Plinii constituendum necessaria est.' The second edition, which is also described by Schweiger and Dibdin, and is a volume of great rarity, was printed by Sweynheym and Pannartz, Romæ, 1470, fol. Those most worth mentioning for their critical excellence are, that by Hardouin, Paris, 1685, 4to., 5 vols., of which a second edition was published, Paris, 1723, fol., 3 vols., and 'is by far the more copious, splendid, and critical performance;' that by Franzius, 8vo., 10 vols., Lips., 1778-1791; and that published by Panckoucke, Paris, 8vo., 20 vols., 1829-33, with a new French translation by Ajasson de Grandsagne, and copious notes by many of the most eminent scientific men of France. The edition by Sillig, Lips., 1831-36, 12mo., 5 vols., is particularly worth noticing on account of its containing the Various Readings of a MS. at Bamberg, which had never before been collated, and which not only inserts words and clauses in several passages that had never been suspected of being unsound (thus proving beyond a doubt that much of the obscurity of Pliny's style may be attributed to the corrupt state of the text), but also adds several sentences at the end of the whole work, and concludes with the following epilogue: 'Salve parens rerum omnium, Natura, teque nobis Quiritium solis celebratam esse numeris omnibus tuis, fave.' Perhaps the two most useful works in illustration of Pliny are the 'Exercitationes Plinianæ' of Salmasius, 2 vols. fol., Paris, 1629; and the 'Disquisitiones Plinianæ' of Latour-Rezzonico, 2 vols. fol., Parmæ, 1763-1767. It has been translated into almost all languages; into Arabic by the famous Honain Ibn Ishak (better known perhaps by his Latinized name *Joannitius*); into Italian by Landino, Venet., fol., 1476, of which magnificent volume there is an account in Schweiger and Dibdin; by Bruccioli, Venet., 4to., 1548; and by Domenichi, Venet., 4to., 1561; into German by Denso, 1764-1765, Rostock, 4to., 2 vols., and by Grosse, 1781-1788, 8vo., Frankf., 12 vols.; into English by Holland, 1601, Lond., 2 vols. fol.; into Spanish by Huerta, Madrid, 2 vols. fol., 1624-29; into old French by Dupinet, Lyon, 1562, 2 vols. fol.; and into modern French by Poinsinet de Sivry, with astronomical notes by Bouguer and Lalande, and mineralogical by Guettard, 4to., 12 vols., Paris, 1771-1782. The best French translation is that in the edition by Panckoucke mentioned above. A Dutch translation was published at Arnheim, 4to., 1617.

PLINY THE YOUNGER. CAIUS PLINIUS CÆCILIUS SECUNDUS was born at Comum, a town on the lake Larius in Insubria. The date of his birth is A.D. 61 or 62; for he himself tells us (*Ep.*, vi. 20) that he was in his eighteenth year when the extraordinary eruption of Mount Vesuvius took place which occasioned the death of his uncle; and this event was in A.D. 79.

Of his father nothing is known, except that his name was Caius Cæcilius, that he was of equestrian family, and that he died in the early days of his son. His mother was Plinia, the sister of Pliny the Elder, at whose house, after losing her husband, she, with her son, took up her abode The young Cæcilius was adopted by Pliny (*Ep.*, v. 8), and was thenceforward called by his name.

His education commenced under the care of his mother and uncle. Verginius Rufus, of whom his pupil has left a grateful record (*Ep.*, ii. 1), was left his tutor. His youthful attainments were of no ordinary kind, for he composed a Greek tragedy in his fourteenth year. After this he went to Rome and studied rhetoric under Quintilian and Nicetes. At the age of nineteen he began to practise in the court of the Centumviri, and he subsequently appeared as an advocate in several cases before the Senate: but though he may have had a competent knowledge of law, it is clear from his own letters that he had no great capacity for difficult legal questions. The following references will show in what kind of cases he was chiefly employed:—v. 8; ii. 14; iv. 16; ii. 11, 12; iii. 4, 8; iv. 9, 16, 24; v. 20; vi. 5, 13, &c.

In his twenty-first year he went as military tribune into Syria, where he met with Euphrates the stoic and Artemidorus, whose society he made available to his improvement in the study of philosophy. He seems, within the space of two years, to have returned from Syria; and we find him resident at Rome until, about the forty-second year of his age, A.D. 103, he was appointed by Trajan proconsul of Bithynia, after he had, with the greatest honour to himself, discharged numerous other offices in the state, and had attained the rank of senator, as is inferred from his letters. (iii. 20; iv. 25.)

He cultivated a friendship with many eminent men, particularly with Tacitus the historian, his senior by a few years, whom he strove earnestly to imitate. Tacitus, on the other hand, held him in no less admiration, and entrusted him with the correction of his own works. Indeed the friendship of Pliny and Tacitus became in a manner proverbial; and they were esteemed the most learned men of their time, 'the duumviri of letters,' as Cellarius calls them.

Pliny was a man of strict frugality and temperance; he was affable and kind to all men; and being possessed of an ample fortune, he was exceeded by none in acts of beneficence, whether public or private. He was twice married, though his second wife only (Calpurnia) is mentioned by name, and she was a very accomplished woman. He had no children.

The time and other circumstances of Pliny's death are uncertain. It is however generally believed that he died about the end of Trajan's reign, which was A.D. 116.

Of many works written by Pliny, we have only his 'Epistles,' in ten books, and his 'Panegyric upon Trajan.' The latter has been always admired as a composition of great excellence. The first nine books of the 'Epistles' are addressed to various persons; the tenth book consists of epistles addressed to Trajan only, with a number of Trajan's answers. These epistles, which abound in useful and entertaining matter, are thus characterised by Erasmus:—'The epistolary style ought to be simple, and, as it were, rather careless; for there is a sort of careful carelessness. As an example, take the letters of Pliny; they are witty, elegant, and appropriate; in them you read nothing but what pertains to domestic every-day life, and everything simply Latin, chaste, and well set off: and, though this style is wrought up and elaborated with much art and ingeniousness, and culture, yet it seems in a manner unlaboured, sudden, and extemporaneous.'

The name of Pliny the Younger has, from the days of Tertullian, been mentioned with peculiar interest by Christian writers on account of the testimony which he bore concerning the Christians of his day in Bithynia. They form the subject of a rather long letter (x. 97) to Trajan, written about forty years after the death of St. Paul, and followed by a short answer from Trajan. With all his advantages of education, Pliny was superstitious and credulous. Though a kind-hearted man even to slaves (viii. 1, 16, 19), he was intolerant and cruel to the Christians; and, according to his own account, he put to death the Christians of Bithynia who would not abjure their religion, though he considered it only an innocent superstition.

The materials for Pliny's life may be collected from his Epistles, from which a brief notice has been drawn up by Cellarius, and one more elaborate by Masson; there is also a very complete Life of Pliny, with abundant references to his letters, prefixed to E. Thierfeld's German translation of the 'Epistles and Panegyric,' Munich, 1828. But the reader is referred to the Epistles themselves for the most gratifying notice of Pliny the Younger, every epistle being, as Melmoth observes, 'a kind of historical sketch, wherein we have a view of him in some striking attitude either of active or contemplative life.'

Pliny's Epistles have been translated into English by Lord Orrery and Mr. Melmoth.

The best edition of Pliny's 'Epistles' is that of Cortius and Longolius, 4to., Amst., 1734. Of the editions of the 'Epistles and Panegyric' together, may be recommended those of Christopher Cellarius, 12mo., Leipzig, 1693; Hearne, with Life, by Masson, prefixed, 8vo., Oxford, 1703; Gierig, 2 vols. 8vo., Leipzig, 1806.

PLOCAMO'CEROS (Leuckard), a mollusk placed by Cuvier in his family *Nudibranchiata.*

PLO'CEUS. [FRINGILLIDÆ; WEAVER BIRDS.]

PLOCK. [POLAND.]

PLOCK, the capital of the government of the same name, is situated on the Vistula. It has about 8000 inhabitants, of whom 3000 are Jews. Plock is the see of a Roman Catholic bishop, who resides at Pultusk. There are in the town 11 churches, 5 convents, an episcopal palace, a Piarist gymnasium, a seminary of secular priests, and various useful institutions, and an orphan-house, a lunatic asylum, a literary society, &c. The inhabitants subsist partly by agriculture and partly by a brisk trade with Danzig and other places.

PLOERMEL. [MORBIHAN.]

PLOMBGOMME—*Hydrated Aluminate of Lead.* This mineral is in small globular and reniform masses, composed of many thin concentric layers. Fracture conchoidal, uneven. Hardness sufficient to scratch fluor-spar, but not glass. Colour yellow, sometimes tinged with brown, and possessing the appearance of gum-arabic. Translucent. Specific gravity 6·425.

When heated by the blowpipe, it loses water, but is infusible per se. With borax it gives a transparent glass.

It is found in the French department of Côtes du Nord.

Analysis by Berzelius:—

PLOT, ROBERT, LL.D. (born 1641, died 1696), a name connected with literature and science in various departments, was the son of Robert Plot, of Sutton-Barne in Kent, and born in that county. He had his early education in the school at Wye, from which he passed to Magdalene Hall, Oxford. He took his Master's degree in arts and both his degrees in law, and then removed to University College. In 1677 he published a 'Natural History of Oxfordshire,' intending to publish similar works on other counties, a work which gained for him considerable reputation. In 1682 he was elected one of the secretaries of the Royal Society, and in the succeeding year was appointed by Ashmole the keeper of the museum which he had founded at Oxford. About this time also he was chosen professor of chemistry in that university. In 1685 he published a tract on the origin of springs, and in 1686 a 'Natural History of Staffordshire,' on the plan of his work on Oxfordshire.

So far his life is that of a naturalist and man of science; but having attracted the attention of the duke of Norfolk by an encomiastic speech which he pronounced when the duke was admitted to the degree of D.C.L. in the University, he was appointed his secretary, and in 1688 was made by King James II. historiographer royal, a privilege being granted to him of access, without the payment of fees, to all the depositaries of the public records. In 1694 he was introduced into the College of Arms by the title of Mowbray Herald Extraordinary, when he was also made registrar of the Court of Honour. What he might have done in the department of history and antiquities, we cannot determine, as he lived not long after he thus deviated from his original path, dying at his hereditary estate at Sutton-Barne, at the age of fifty-five. He can hardly be said to have established a permanent reputation.

PLOTI'NA. [TRAJANUS.]

PLOTI'NUS, the most celebrated writer and teacher of the Neo-Platonic school at Alexandria, was born at Lycopolis in Egypt, A.D. 204. At the age of twenty-eight he betook himself to the study of philosophy, and attended the lectures of most of the teachers who then flourished at Alexandria. He attached himself more particularly to Ammonius, the founder of the Eclectic school, and studied for eleven years under that master. The expedition which the emperor Gordian undertook against the Parthians in A.D. 243 furnished an opportunity, which Plotinus had long coveted, of forming a personal acquaintance with the sages of the East, whose doctrines were so much commended by the philosophers of the Alexandrian school, and were supposed by them to have formed the basis of many of the speculations of their great master Plato. Accordingly, Plotinus joined the army of Gordian, which he accompanied as far as the Euphrates, and when the emperor was murdered there, he fled first to Antioch and then to Rome. During the first ten years of his residence at Rome, Plotinus contented himself with giving oral instruction to his pupils, but at last, in his fiftieth year, he was induced by the importunities of Porphyry, the most famous of his disciples, to commit to writing the substance of his lectures. He remained at Rome till his death in A.D. 274, and during all that time he was busily engaged as a teacher of the Eclectic or Neo-Platonic doctrines. He was a great favourite with the emperor Gallienus, who was on the point of allowing him to rebuild a ruined city in Campania, in order that he might try the experiment of establishing an Utopia there after the model of Plato's republic. He died in Campania, not on the scene of his projected city of philosophers, but at the house of a friend, who maintained and attended him during his sufferings under an accumulation of diseases.

The works of Plotinus consist of fifty-four books, which were divided into six *Enneads*, or sets of nine books, by his pupil Porphyry, who endeavoured to reduce them to intelligible order, and to correct the obscurities and other faults of style under which they laboured. He is perhaps one of the most mystical and confused authors in any language, and we shall not wonder at this if we recollect some of the facts which Porphyry has told us about his method of composing. We have already mentioned that he did not begin to write till he was fifty years old, and then he seems to have set down his thoughts quite at random and as they occurred to him. His hand-writing was very bad, and his spelling very indifferent; his eye-sight was so weak that he could hardly read his own writing, and he could never be brought to revise his works. When we add to this that his subjects were the most abstract that could be devised—'On entity and unity;' 'On the essence of the soul;' 'On the unity of the good;' 'Whether there be many souls or only one soul?' and so forth—it will perhaps be considered that he is not a very inviting author. Nevertheless, he has found many admirers, and has, either directly or through his follower Proclus, exercised a most important influence on the opinions of more recent philosophers, especially among ourselves. Cudworth, Henry More, Norris, Gale, and others were students rather of Plotinus and Proclus than of Plato himself; and the gnosticism of some sects of Christians, with the pantheism of Spinoza and others, may be fairly traced to this obscure writer and his school. We know nothing further of Plotinus than what is contained in his Life by his pupil Porphyry.

A superb edition of the works of Plotinus, in 3 vols. 4to., has been recently published at the Oxford University Press, with this title: 'Plotini Opera Omnia. Edidit Fridericus Creuzer. Oxon. E Typographeo Academico, 1835.' There is an English translation of 'Select Works of Plotinus,' by Taylor.

PLOTTING. [SURVEYING.]

PLOTUS. [PELECANIDÆ.]

PLOUGH. That the plough is an instrument of the highest antiquity is apparent both from the oldest writings that we possess and from the existing monuments of Egypt We might exercise our imagination in supposing a probable origin of the plough in the branch of a tree dragged along the ground, in which the stump of a smaller branch made furrows as it went on. It seems indeed probable that some accidental circumstance first suggested this mode of stirring the earth to prepare it for receiving the seed.

The oldest forms of the plough of which we have any description in antient authors, or which are represented on monuments and coins, are very simple: a mere wedge, with a crooked handle to guide it, and a short beam by which it was drawn, form the whole instrument. The light Hindu plough, now in use in many parts of India, seems to differ little from the old model.

Before we enter into any details it may be as well that we describe the different essential parts of a plough, by the names which are usually given to them.

The body of the plough is that part to which all the other parts are attached. The bottom of it is called the *sole*, or *slade*, to the fore part of which is affixed the *point*, or *share*; the hind part of the sole is called the *heel*. The *beam*, which advances forward from the body, serves to keep the plough in its proper direction, and to the end of it are attached the oxen or horses which are employed to draw it. Fixed in the beam, in a vertical position, before the point of the share, with its point a little forward, is the *coulter*, which serves to cut a vertical section in the ground, while the point of the share, expanding into a *fin*, separates a slice by a horizontal cut from the subsoil or solid ground under it. The *mould-board*, or *turn-furrow*, is placed obliquely behind the fin, to the right or left, in order to push aside and turn over the slice of earth which the coulter and share have cut off: it thus leaves a regular furrow wherever the plough has passed, which furrow is intended to be filled up by the slice cut off from the land by the side of it, when the plough returns. The stilts or handles, of which there may be either one or two, as is thought more convenient, direct the plough by keeping it in the line required and at a regular depth in the ground. The single stilt appears to be the most antient form.

Wheels are a modern invention in comparison with the other parts. They support the end of the beam, and prevent it from going too deep into the ground or rising out of it while the plough is going on. The greatest improvements introduced into modern ploughs are in the shape of the mould-board, or turn-furrow, of which we shall take particular notice, and the contrivances for regulating the line of draught, so as to make the plough go at an equal depth, and cut off a regular slice of equal breadth, without any great force being applied by the ploughman who holds the stilts.

The Hindu plough consists of a slight beam, often without any coulter, a narrow share, and a corresponding stilt. The whole is of wood, slightly pointed with iron. It is so light that a man can readily carry it upon his shoulder. When it is at work it is usually drawn by a small buffalo, and sometimes by a man or a woman. This instrument is intended merely to make a shallow furrow in a very light soil, or in the mud produced by irrigation where rice is cultivated. It does not act as our ploughs do, nor does it turn over a regular furrow, but it acts more like one of the tines, or teeth, of some of our more complicated instruments called cultivators or grubbers, with which the earth is stirred without being turned over.

The Chinese plough resembles the Hindu in its simplicity. The earth is turned over by holding the instrument obliquely, and much depends on the art of the ploughman, in whose hands it is like a stout shovel pulled through the ground by a horse or ox. The sole is not straight, but rounded, like the bottom of a boat. The work done by this instrument is not unlike the furrow drawn in the sand at the bottom of the sea when a ship drags her anchor.

The ploughs in use in different countries in Europe have undergone little change for many centuries; it is only lately that any attempt has been made to vary the old forms.

The Roman plough, such as is described by Virgil in the 'Georgics' (i. 174), is still used in many parts of France, under the name of *Araire Romain*. It consists of a beam (*temo*), a body (*buris*), a share (*vomer*), and a handle or stilt (*stiva*). The office of the turn-furrow is performed by two pieces of wood about six inches long projecting obliquely upwards, and very properly called teeth (*dentalia*), E F (*Fig.* 1) The sole of the plough AB has two pieces of wood CG and DH fixed to it on each side, forming an acute angle with it, in which the teeth are inserted. This exactly answers the description of Virgil, 'Duplici aptantur dentalia dorso' (the teeth are fitted to the double back). These teeth help to push aside the earth to the right and left, and the instrument resembles what is called a moulding plough, which is used in throwing the soil aside against young plants growing in rows, as turnips, potatoes, &c. A chain or pole connected with the end of the beam was hooked to the middle of the yoke on the neck of the oxen, and thus the plough went on making parallel furrows, so near to each other that the preceding furrow was partially filled with the earth which the dentalia pushed aside. The point was in the shape of the head of a lance. This plough might suffice in light mellow soils, which had been long in cultivation and had more the texture of garden mould than of stubborn clay.

Fig. 1.

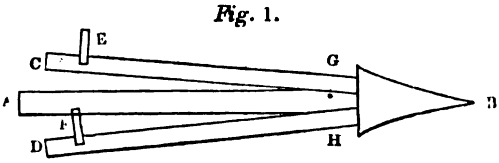

Fig. 2.

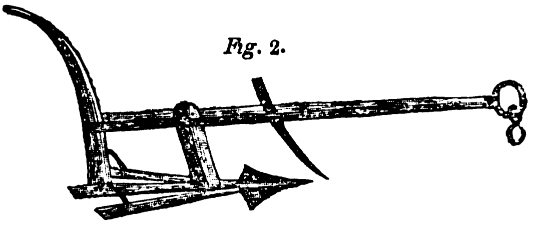


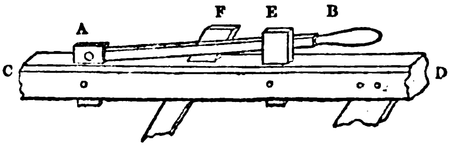
Roman Plough.

The small double mould-board plough, common in other parts of France, is evidently taken from this. The teeth not being sufficiently strong, a slanting board was substituted on each side, and wheels were added, to diminish the labour of the ploughman. The stilt remained the same at the place where it is attached to the plough, but higher up it was divided into two, like a fork, for the convenience of holding it with both hands. This plough acts exactly like the other, but it is stronger and better adapted for heavier land. Neither of them goes much deeper than four or five inches, leaving shallow parallel ridges, in which the seed falls, and is buried by light wooden harrows, which are drawn over the land after sowing. This is an imperfect tillage, the bottoms of the furrows being only partially stirred. The broad flat share, and the single mould-board which turns the earth completely over, after lifting it up, is a far more effectual instrument, and has been adopted wherever agriculture has made any improvement. This plough more nearly imitates the digging with a spade; and the more perfect the imitations, the better is the work.

The mould-board of a modern plough is either fixed on one side, or made so as to be shifted from one side to the other. In the first case half the furrow-slices lie on one side and half on the other, and there is of necessity a double furrow where they join. When it is desirable that the surface should be quite flat, and the furrow-slices all in one direction, the mould-board must be shifted at every turn, and a plough which admits of this is called a turn-wrest plough.

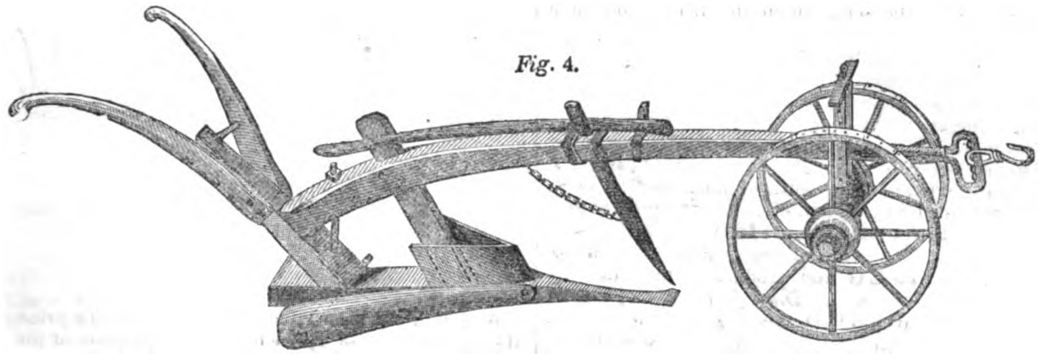
It is evident that the mould-board of a turn-wrest plough must be so constructed as to act with either side uppermost; it can therefore have only a very slight convexity to push over the slice cut off by the coulter and share; and a considerable force is lost by the obliquity of the action in doing so. The share of this plough is pointed like a lance, or presents a flat edge like a broad chisel, according as the soil is light or heavy. The point of the coulter is placed on line with that side of the point which is nearest to the unploughed land, and this is done by means of a piece of wood AB (*Fig.* 3), which presses it against one side or the other of the mortice in which it is placed in the beam CD, by changing the position of the pieces AB to the other side of the projection

Fig. 3.



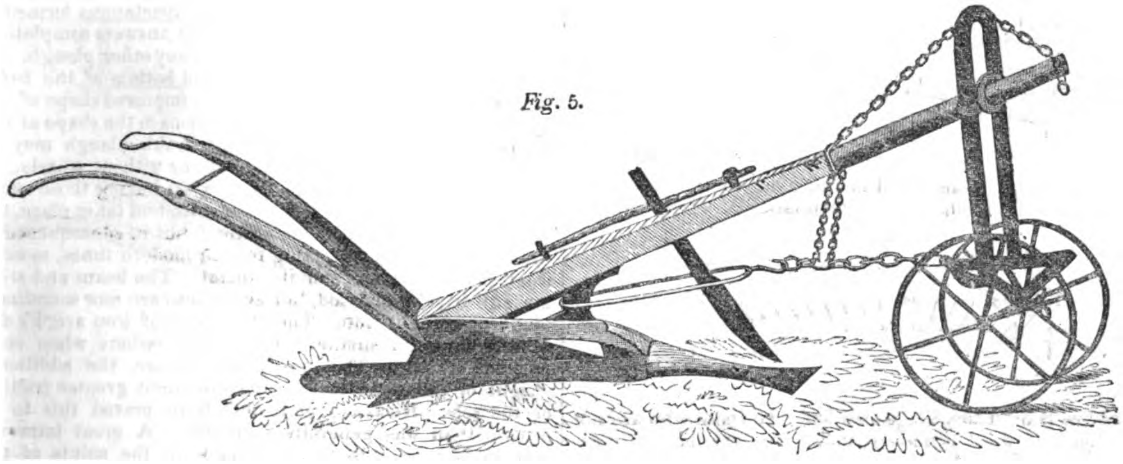
E on the beam, and pressing the head of the coulter F to the other side. The mould-board has a hook at the fore part, which goes into a staple in the side of the fore-part of the body of the plough towards the preceding furrow: a piece of wood on the inside of the mould-board keeps it at the proper angle with the line of the sole.

Fig. 4.



Kentish Turn-Wrest Plough.

Fig. 5.



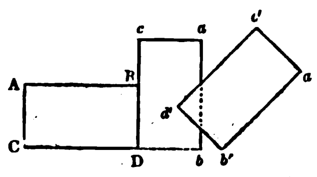
Ransom's Kentish Turn-Wrest Plough.

The defect of this plough is in its weight and clumsiness more than in the shape of the mould-board; for when it is made lighter, it is not so bad a construction as appears at first sight, and it does its work very neatly in heavy loams with a dry subsoil. If, instead of one mould-board, two were used alternately, of a better shape for turning over the furrow-slice, this plough would be much improved.

The form of the turn-furrow is of material importance, for on this depends not only the perfection of the work, but also the lightness of the draught. When we follow a plough working in a mellow soil which slightly adheres to the plough, we often perceive that, instead of being turned aside, the earth is carried forward, and only falls off when the accumulation of it becomes heavy enough to overcome the adhesion. It does not slide off from the mould-board itself, but separates from the earth which adheres to the latter; thus showing that the shape is defective, and giving good hints for its improvement. But as the same plough will sometimes turn over the same earth better when it is either drier or moister, it is very difficult to determine, by experiment only, what may, on the whole, be the best shape. A little reflection and the application of scientific principles may greatly assist us here. It is not sufficient however to find the curve which will make the plough go through the ground with the least force. The plough must also perform its work perfectly, and if anything is to be sacrificed, it is better to employ more power than to plough the ground badly. After having ascertained the mechanical principles which bear on the working of the plough, we must observe its action carefully, follow the plough day after day, in different soils and different weather, and thus we may be led to observe all the circumstances which attend its operation, and correct any mistakes which an erroneous theory might have led to.

Many attempts have been made to ascertain the exact curve which the turn-furrow should have to perform the work well and at the same time to produce the least resistance. The difficulty of the problem lies in determining the data, or principles on which the investigation is founded; and these are so various, that it is not surprising that no very satisfactory conclusion has yet been obtained. We will make an attempt at a solution from a simple examination of the motion to be produced in the portion of earth to be turned, which we call the furrow-slice. We shall suppose this separated from the adjacent soil by the vertical cut of the coulter, and at the same time from the subsoil by the horizontal cut of the share; a section of the slice, by a plane at right angles to the line of the ploughing, will be a parallelogram A B D C (*Fig.* 6), the depth A C being the thickness of the slice, and A B its width. Confining our attention to this section of the slice, the object is to move it from its position A B D C, as cut off by the coulter and share, to that of $b'd'c'a'$, where it is

Fig. 6.

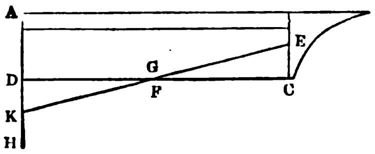


inclined at an angle of 45° to the horizontal line; the surface A B ($b'a'$) being laid on the slice previously turned over, so as to bury the grass or weeds which might be rooted there, exposing the roots to the sun and air. The more uniformly this motion is produced, and the more regularly the successive sections follow each other, the less power will be required to turn over the whole slice. The motion of C D round the point D must therefore be uniform. If the turn furrow is horizontal at the point where it joins the share, and of the same width as the furrow-slice, it will slide under the slice; and if the vertical sections of its upper surface, at equal distances from the share, are inclined at angles regularly increasing with this distance till it arrives at the perpendicular, the turn-furrow will, as it advances, turn the slice from a horizontal to a perpendicular position: the section of it will then be D*cab*. The inclination of the section of the turn-furrow must now be to the other side, forming an obtuse angle with the section of the sole, until it has pushed the slice over at the required inclination of 45°

which theory and experience have shown to be the best adapted to expose the greatest surface to the action of the atmosphere, and likewise to form the most regular furrows for the reception of the seed, which the harrow can then most readily bury.

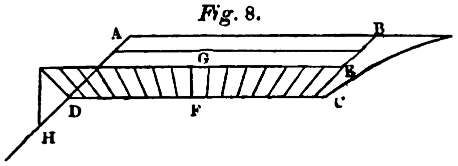
The surface of this turn-furrow is curved in the form of the spiral thread of a screw, such as would be generated by a line moved uniformly forward in a direction at right angles to its length, while it revolved uniformly round one of its extremities. This surface is easily constructed mechanically thus: take a rectangular parallelogram A B C D (*Fig.* 7) of the width of nine inches, or as wide as the intended furrow, and of a length equal to four times the width. Bisect B C in E and DC in F; at F raise a perpendicular F G to the plane of the rectangle, and make it equal to C E. Join E G and produce it to K, making F K equal to F E. Join K D. Draw from every point in C D lines at right angles to C D, meeting the line E K in different points: these lines will form the required surface.

Fig. 7.



The line K D will be found inclined 45° to the horizon at the angle K D H, which is the inclination at which the furrow-slice is most advantageously laid. To those who are not familiar with solid geometry, these lines may be easily exhibited by means of a wire inserted at E and bent at a right angle at K, inserting the bent portion into the board A B C D (*Fig.* 8) at D, so that it shall be inclined 45° at D, lying in the direction E K in *Figs.* 7 and 8. Care must be taken that G F be equal to C E and perpendicular to the board.

Fig. 8.



It is evident that, as the plough moves on, a particle at E will slide along the line E K, become at G perpendicular to the bottom of the turn-furrow, which should be parallel to the sole, and at K be at an angle of 45° with that line. If the slice were a solid substance, this line E K would be all that is required to turn it in its proper position; but as the soil is generally loose, and would crumble to pieces, a support must be given to it by a surface at least as wide as the slice. This surface is generated by drawing lines from different parts of D C at right angles to this line, and meeting the line K E (*Fig.* 9). These lines will be at different angles to the horizon, nearly horizontal at C, where the fin of the point begins perpendicular at F, and at 45° beyond it at D. The curve thus generated will be found to turn over soils of a moderate tenacity very perfectly. If it is very light, the surface may be formed by arcs of circles with a considerable diameter, the concave part upwards; if it is very tenacious, the convex part of the arches may be upwards. Thus the surface may be varied without altering the fixed line E K. The annexed figures (10, 11, 12) will explain this. The distance of the perpendicular F G from the fin of the share may also be varied, either lengthening or shortening the turn-furrow, as experience may show to be most advantageous.

Fig. 10.

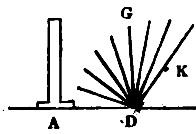

Fig. 11.

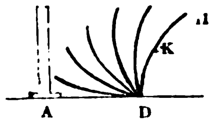

Fig. 12.

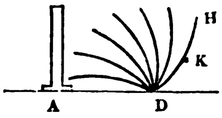

A plough has been lately constructed on this principle by Messrs. Ransom of Ipswich, at the suggestion of the writer of this article, and exhibited at the meeting of the Royal Agricultural Society of England, held at Cambridge, July 15, 1840. It promises to realise the expectations formed of it. In soils of a loose mellow nature it answers completely, and does the work more perfectly than any other plough. It unites the parallelism of the sole and bottom of the turn-furrow of the Flemish plough with the improved shape of the turn-furrow. By adopting the variations in the shape of the turn-furrow which we have suggested, this plough may be adapted to any soil, and be used with or without wheels.

Ploughs were formerly made of wood having those parts covered with iron where the greatest friction takes place, the share and coulter only being of iron; but in consequence of the greater facility of casting iron in modern times, most of the parts are now made of this metal. The beam and stilts are still usually of wood, but even these are now sometimes made of wrought-iron. The advantages of iron are, its durability and the smaller friction it occasions when once polished by use. The inconveniences are, the additional weight of the instrument, and consequent greater friction of the sole. Recent experiments have proved this to be greater than was generally suspected. A great improvement has been introduced by making the points of the shares of cast-iron, which, by a mode of casting the lower surface on a plate of metal, makes one surface much harder than the other; and as the softer surface wears more rapidly, a sharp edge is always preserved.

The different parts of a plough are now usually cast, so that if any one fails or wears out, it can be instantly replaced by moving a few screws or bolts. This is a very great saving of time and expense; for before this, every time an accident happened to any part of the plough, it took a long time to repair it, and in the mean time the labour was suspended, often at a very critical time of the year. There is another advantage in having the essential parts of cast-iron. If any particular shape has been once discovered to be the best for any part, that shape is preserved without deviation in every plough made on the same pattern, and with respect to the turn-furrow this is of the greatest importance.

The stilts of the plough are mostly of wood. Where the soil is light and crumbling, without stones, as in Norfolk, a single handle or stilt is sufficient; but where some force is occasionally required to prevent stones or other obstacles from turning the plough out of its course, two stilts are most convenient, placed at a more obtuse angle with the sole of the plough.

The force required to draw a plough depends not only on the nature of the soil, but also on the shape of the plough, and especially on the position of its different parts with respect to each other, so that they do not counteract each other.

If a plough were drawn in the direction of the sole, the obliquity of the turn-furrow would cause it to turn towards one side, and it would require a considerable force to keep it straight. In order to prevent this, the line of draught is placed at an angle, which varies with that of the turn-furrow and the force required to push the furrow-slice over. To adjust this angle, so as to cause the plough to keep in the intended line, there is a contrivance at the end of the beam to change the position of the ring by which the plough is drawn to the right or left of the line of the beam, and another by which it may be raised or lowered. In most ploughs the beam, having been originally set at a small angle with the sole towards the right, has an arch of wood

Fig. 13.

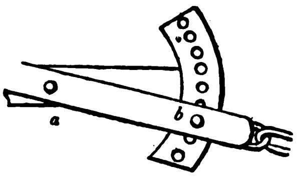

Fig. 14.

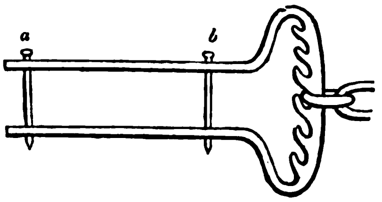

Fig. 15.

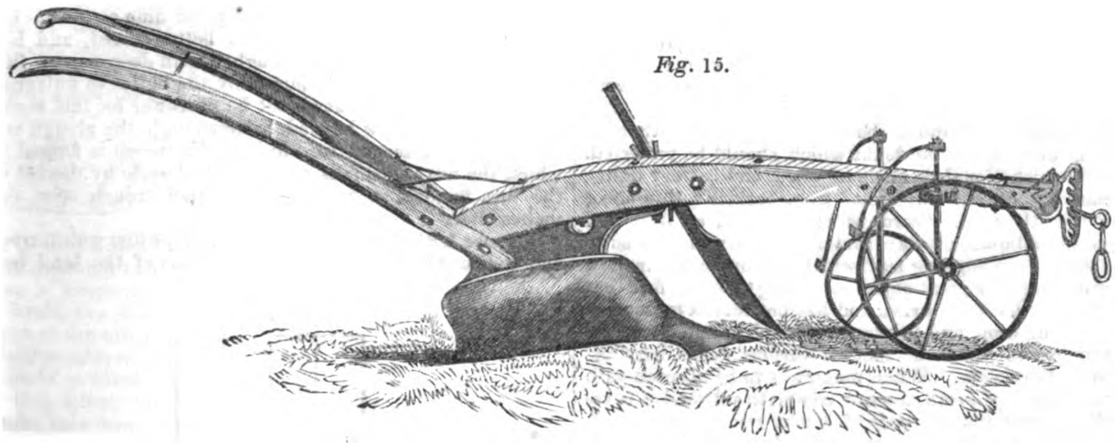
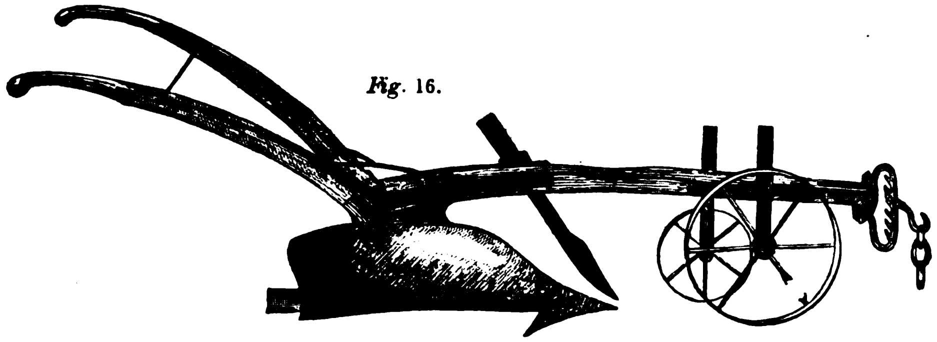


Ransom's Rutland Plough.

Fig. 16.



Bedfordshire Plough with Wheels.

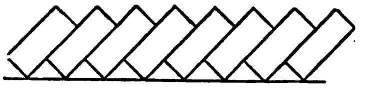
or iron at the end, as in the annexed *Figure* 13. An iron, shaped as in *Fig.* 14, is made to embrace the beam, to which it is attached by a pin (*a*), round which it turns as a centre. Another pin (*b*) passes through one of the holes in the circular end, and keeps the iron in any required position to the right or left of the line of the beam. The end of this iron, which is called a bridle, has several projecting hooks in the oblong curve which terminates it, on which an iron ring is hung at different heights. By these contrivances the plough may be drawn from a point on either side of the beam, and higher or lower as may be required. When the plough is found to *take too much land*, as ploughmen say, that is, tends to increase the width of the slice cut off by the coulter, the bridle is shifted to the left by moving the pin (*b*) into another hole: when it goes *out of the land*, as it is called, that is, diminishes the width of the furrow-slice, the pin is moved a hole or two to the right, until the plough has no tendency to deviate to either side. If it inclines to rise out of the ground, the ring is shifted in the iron bridle and placed in a hook or notch higher up; if, on the contrary, it dips too deep, the ring is hooked lower. Thus a plough may be made to go straight and at a regular depth, without any more force being applied to the stilts than is required to counteract inequalities in the land, or accidental obstacles, such as stones or roots, which might throw the plough out of the ground. When the soil is of unequal texture, it is useful to have a small wheel connected with the fore part of the beam, so as to prevent its dipping downwards, which would require a great pressure on the stilts to keep the point of the share up, and thus increase the friction of the sole on the ground, and consequently the labour of the horses. In the Rutland and Bedford ploughs two wheels are connected with the beam, one of which runs in the furrow to the right, and the other on the unploughed soil to the left. When the plough has been well adjusted, and the larger wheel runs in the angle of the furrow, it acts as a gauge to regulate the width of the slice as well as its depth: in very uniform soils without stones, the plough, when set in the proper direction, will make a very straight and even furrow parallel to the one in which the wheel runs, without any person holding the stilts; so that all that is required is to turn the plough at the end of each furrow, and set it in to the proper line to form the next. As this admits of very correct adjustment, no unnecessary force is required to draw the plough: and hence this plough appears to be the easiest for the horses; and if the wheels are not very heavy, and the plough is of a good form, it certainly requires less power to move it than many which are without wheels; and it is far superior to the old clumsy wheel-plough, the beam of which rests on a heavy carriage, without being firmly attached to it. This, instead of lessening the draught, increases it by all the pressure of the beam upon the carriage, besides the weight of this last and of the wheels. There are some very irregular and stony soils, where a common swing plough can scarcely be kept steady without the help of wheels, and where it would not be so convenient to have the beam fixed on the wheels. In this case a separate carriage is necessary, that the ploughman may have a fulcrum on which he can raise his plough, or turn it to either side to avoid any considerable stone or other obstacle. As a general rule, it may be safely asserted that a slight but strong swing-plough, in the hands of a clever ploughman,—with one wheel in particular soils, but, in general, without any wheel,—will effect its purpose with the greatest precision, and the least exertion of the horses drawing it. Theory and practice agree in this; and if any experiments appear to throw a doubt upon it, we shall probably find some circumstances which have influenced the result, when wheel-ploughs have appeared to require the least power of draught. But wheels have one advantage: they will enable an inferior ploughman to make better work than he could possibly do without them; and that too with less labour to the horses; because, from his want of skill, the swing-plough would be continually subject to sudden deviations, requiring him to use his strength to counteract them; and each exertion of the ploughman adds to the labour of the horses.

Some interesting experiments have been made on the draught of different ploughs by Mr. Handley, M.P. for Lincolnshire, and Mr. Pusey, M.P. for Berkshire, which are detailed in the third and fourth numbers of the Journal of the Royal Agricultural Society.

Without entering into any comparison of ploughs differently constructed, it is evident that the shape of the plough must vary with the nature of the soil which it is to turn up. A light soil must be shovelled up; a mellow one may be turned over with any kind of mould-board; a very stiff tenacious soil which adheres to any surface pressed against it, will be more easily turned over by a few points of contact which do not allow of adhesion. Hence the point and turn-furrow have been made of all imaginable shapes, and while one man contends for a very concave form, another will admit of nothing which is not very convex. That plough will no doubt have the least draught which is best suited to the soil which it has to move. The lighter the plough is, consistently with sufficient strength, the less draught it requires, all other circumstances remaining the same. Lightness and strength combined are consequently great advantages, and if a very light plough does its work as well as a heavier, there can be no doubt that it is preferable. Durability is nothing compared with the saving of one horse in three: it is cheaper to have a new plough every year than to keep an additional horse all the year. If a wooden plough is found to be more easily moved than an iron one, there can be no doubt which should be preferred.

The Flemish plough is made of wood, and is very light; the share and coulter only are of iron, besides a thin sheet of iron over the mould-board, which is shaped as if it had been rolled obliquely over a cylinder, a shape well adapted to sandy soils. In ploughing land which is more or less mellow and crumbling, the great object is to bring to the surface that portion which has lain buried, and has not served to nourish the preceding crop, and to bury that which has produced vegetation, and in which the roots of various weeds have established themselves. When manure is to be covered with a certain depth of earth, a more complete subversion is required, in order that no part of it may remain uncovered. When the land is in a compact state, from the roots which pervade it, and it is only ploughed once to prepare it for receiving the seed, much greater nicety is required to lay the slices at a certain angle so as to leave regular lines or depressions in which the seed may fall and be readily covered by the harrows which follow. In this case the angle of 45° is found to be the most convenient at which the furrow-slices may be laid against one another. The field will then have the appearance of being laid in small ridges as in the annexed figure, all towards the same side if ploughed with a turn-wrest plough, or towards a middle line if a plough with a fixed turn-furrow has been used. To produce this regularity, the end of the turn-furrow is made to press on the slice turned over; and some ploughmen fix a piece of wood or iron to the end of the turn-furrow, which makes a groove in the furrow-slice at the place where the next one will be laid upon it. This prevents useless openings between the slices. It adds no doubt to the draught, but it makes better and neater work.

Fig. 17.

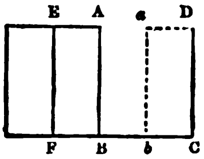


When the seed is to be dibbled on the sward, which is reversed by a single ploughing, it is necessary that the sod should be completely turned over and laid flat. To do this, and at the same time to bury all the grass, requires the furrows to be very equal and parallel; so that when a roller has gone over the land, it is perfectly flat, without any interstices between the slices which are turned over. It requires a good ploughman to do this perfectly.

When clover-ley or old grass is ploughed up, it is difficult to bury all the grass which grows on the edge of the slice; and if it remains exposed, it will grow and increase to the detriment of the corn. To prevent this, a wing is sometimes added to the side of the coulter, a few inches from the point. It cuts a small horizontal slice off the surface before the sod is turned over, and this falls into the bottom of the furrow and is buried there. The coulter with such a wing is called a skim-coulter, because it, as it were, skims the surface. This instrument may require an additional horse to be put to the plough in tenacious soils, but this cannot be avoided. There is no doubt that no more horses should be put to a plough than can do the work; but whatever be the number required, the work must be done well. There is no saving in doing the work imperfectly. The discussions about the number of horses which should draw a plough might easily be settled, if the nature of the soil were sufficiently taken into consideration. The shape of the plough may make some difference, but the tenacity of the soil makes a much greater. It is however not a little surprising that there should be so little variety in the width of the furrows. It would appear as if there were a law prohibiting furrows less than eight inches wide, or more than ten: a furrow-slice five inches wide and ten deep requires no more power than one ten inches wide and five deep. It is true that a plough will not do more than half an acre at most in a day with narrow furrows; but if two horses will do this, and two ploughs instead of one be used, with one man and two horses each, an acre will be ploughed in a day with four horses and two men, which is the number usually employed, when the furrows are deep and nine or ten inches wide; but the land will be much better stirred, and laid more even. The Romans ploughed with deep narrow furrows, and varied the width purposely, the better to pulverise the soil. The plough need not be narrower for this work; for if the first furrow be made wide enough, the plough can deepen it by a second turn in it, and a trench is formed in which the next slice falls, and is pushed aside by the tail of the turn-furrows, so as to leave another trench open ten inches wide.

Suppose ABCD (*Fig.* 18) the section of the first wide furrow, and a slice AEFB is cut off the solid side of the land half the width of the trench; the mould-board pushes this earth, after it has been turned over, into the space DC*ab*, marked with the dotted line, and in doing so beats and crumbles it, leaving a fresh trench *ab*FE equal to the first, and so the whole field may be ploughed without difficulty. In nine cases out of ten, where the soil is properly cultivated, and ploughed in a proper state, this mode of ploughing would be found a great improvement, and equal to a trench ploughing, or subsoil ploughing. Where the farms are small and few horses are kept, deep ploughing is not practicable with the usual width of furrow; but with a narrow furrow, the land may be moved to a very great depth with a couple of horses. The plough must be made sharp and narrow, and the turn-furrow not much curved, so as rather to push the earth aside than to lift it.

Fig. 18.



Very little attention was formerly paid to the straightness of the furrows. It was natural to follow the shape of the boundary of the field, which was seldom straight; and this practice increased gradually till no straight furrow was to be seen; and there was a prejudice, if not a superstition, in favour of crooked ridges. Those who defended them with the least vehemence, asserted that if crooked furrows were not better than the straight, the difference was unimportant; but no curves can be laid so perfectly parallel as two straight lines. Every deviation from parallelism causes a defect in the contact of the slices, and a loss of force by the obliquity of the draught. A superficial observer would not perceive this, but minute examination proves it. Hence equal and straight furrows are a sign of good ploughing.

When the land lies on a dry subsoil, and no more moisture remains in it, after continued rains, than is useful to promote vegetation, it may be ploughed quite flat. This may be done by a plough with a moveable turn-furrow, or by ploughing in a continued spiral from the centre to the circumference, or the reverse. In this case straight furrows cannot be made. The best way is to draw a furrow the whole length of the field in the middle, and plough towards this from both sides. If the field is wide, it is most convenient to plough it into several broad stitches, each a certain number of perches in breadth. A perch (16½ feet) is a very common width for a stitch, and convenient to guide the sower or the drilling-machine.

But on moist impervious subsoils it is necessary to lay the land in a rounded form, in order to let the superfluous water run off into furrows, from which it is conducted by proper channels into the ditches. In this case half a perch is a common width for each stitch, or land, as it is sometimes called. It requires some practice to lay up a land in a rounded form from a flat surface. After cross-ploughing and harrowing, the first furrow is drawn wide and shallow, and the earth is thrown upon the surface to the right: when the plough returns, it takes another furrow about nine or ten inches from the first, laying the earth or furrow-slice somewhat obliquely over the first. At the next turn another slice is laid, meeting the last at an angle, the first slice being quite covered by the two last. This now forms the crown of the ridge; and the succeeding slices are laid obliquely, leaning to the right and left till the required width is obtained. Another land is now begun at the distance of a quarter of a perch from the last furrow, and laid exactly in the same manner. When the two lands meet, the intervening furrow, which had been purposely left shallower, is deepened; and there is a furrow between every two lands, the bottom of which is considerably below the bottom of the other furrows. When this field is ploughed again after harvest, the work is reversed; the furrow between the lands is filled with the first slice, and another is placed over this, which now becomes the crown of the land to be formed: this is called ploughing crown and furrow. When the lands are ploughed towards the crown, it is called gathering. By gathering several times in succession, the soil is much raised at the crown at the expense of the sides. This was the old practice, when lands were laid very wide and very high; in common fields, the land or stitch was often the whole width of the possession, from which came the name of land. In Scotland they are called riggs.

Fig. 19

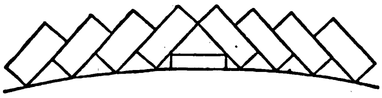


Fig. 20.

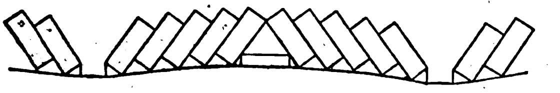


One of the most useful operations in ploughing land is to cross the former furrows, by which means the whole soil is much more completely stirred; and if any part has been left solid without being moved by the plough-share, which is called a balk, it is now necessarily moved. The leaving of balks is a great fault, and is owing to the sole of the plough being narrower than the furrow-slice, and the wing of the point too short, or to the ploughman not holding his plough upright. The share should cut the ground to the whole width of the furrow, that no roots of thistles, docks, or other large weeds may escape and grow up again. The Roman authors recommended the use of a sharp rod or stake inserted horizontally into the ground, to discover if there were any balks, which, with their ploughs, must have been often left, if the ploughman was not very careful to make close and small furrows. Many ploughmen hold the plough in an oblique position; the bottom of the furrow is consequently not level, and the soil is not stirred equally. This is a great fault, especially in wet ground; for the furrows thus become channels in which the water remains, not being able to run over the inequalities of the bottom. It is of no use to lay the surface convex, if the solid earth below lies in hollows or gutters. The water naturally sinks down into the newly-ploughed land, till it meets the solid bottom which the plough has gone over; if it can run over this into the deeper furrows between the stitches, it evaporates or runs off, and the land is left dry, and so consolidated as to let the water run along the surface without sinking to any depth; but if the bottom is uneven, it remains in the hollows, and stagnates there, to the great injury of the growing crops.

There are various modes of ploughing land when it is intended to pulverise and expose it to the sun in summer, or the frost in winter, to purify and fertilise it. To expose as great a surface as possible, the whole field is laid in high and narrow ridges, bringing to the surface all the fertile portion of the soil, and often also a portion of the subsoil so as to deepen the productive portion and give more room for the roots to spread in. The simplest method of increasing the surface exposed, when the land is first broken up from pasture, or after having been some years in grass, and is in a foul state, is called ribbing. The plough turns up a slice, which it lays over flat on the adjoining surface. It does not cover this with the next slice, as if it were beginning the crown of a stitch, but it takes another slice at some distance, and then one parallel to the first, likewise laid flat on the solid part. When the whole field has been so ploughed, the surface consists altogether of ridges and furrows; but only half the surface has been ploughed. No grass appears, if it has been well done, the unploughed strips being covered by the slices raised by the side of them, the two surfaces with grass on them cover each other. It is left in this state till the grass is rotten, and when the sod is broken to pieces by heavy drag-harrows, the land can be cross-ploughed and cleaned or fallowed in dry weather.

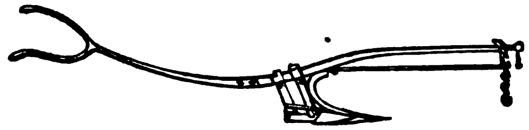
There is another mode of ridging, when the land has had one or two ploughings, in order to expose it to the frost in winter, and to mellow it. The operation is somewhat similar to ribbing, but after the first slice is turned over, another is added, as deep as the plough can be made to go, so as not to bring up the subsoil; by this means the whole surface is laid in high ridges and deep furrows; and when this ploughing is reversed, in spring, the soil which has been exposed to the frost and wind is mixed with the rest, and tends greatly to mellow it. This is an excellent preparation for turnips, if the land has been well cleaned. The manure, being distributed in the deep furrows, is covered by the plough right and left, or at one operation by a plough with a turn-furrow on each side, which divides the ridge and lays half of it in each contiguous furrow. This plough is usually called a double mould-board plough, and is extremely useful in many operations of husbandry.

In order to save hands and expedite the tillage of the land, ploughs have been contrived which make two or more furrows at once. When they are well-constructed, they are very useful in light soils. If it is not required to go deep, and two horses can draw a double plough, there is a decided saving of power; but if it requires four horses, nothing is gained. The double ploughs are therefore not much in use. But there are instruments which cultivate the earth, stirring and pulverising it much more speedily than the plough. Some of these will stir the ground to the depth of seven or eight inches, going over a width of five or six feet at once. Such an instrument is preferable to the plough, after the ground has already had a certain degree of stirring, and is become mellow and crumbling; but to break up pasture or clover-ley, there is nothing so efficacious as the plough, which cuts regular slices and lays them over, so that all the grass shall rot, and the roots, being exposed to the air, shall decay, and thus furnish food for other crops.

The instruments which have been invented to save the time and labour required by repeated ploughings are very numerous. Some of the most useful have been noticed before. [Arable Land.] New ones are daily invented, and some are supported by wheels, which render them both lighter and more convenient. They are easily raised out of the ground, when not intended to work, and the depth to which they are let down is more easily regulated.

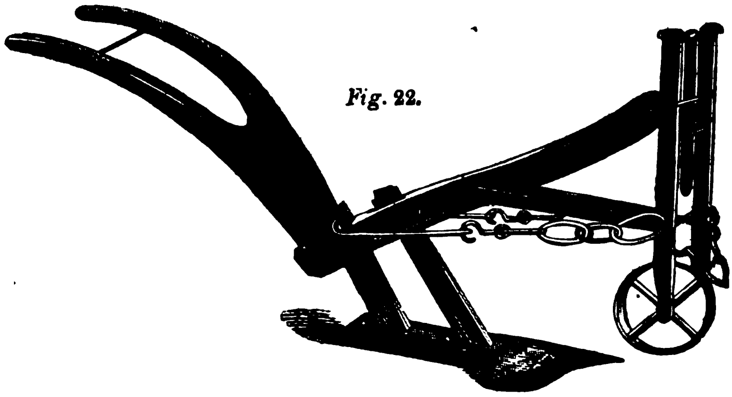
Deep ploughing is generally acknowledged to accord with the best husbandry, where the subsoil is dry naturally, or has been artificially drained; but some inconvenience may arise from bringing a barren subsoil to the surface, in trench-ploughing by two ploughs following each other in the same furrow. It has therefore been suggested to take off the turn-furrow from the plough which follows the first, so as to stir the subsoil without bringing it to the surface. [Arable Land.] This idea has been improved upon by constructing a subsoil-plough of great strength, which will go very deep into the ground and stir the subsoil a foot or more below the bottom of the usual furrow. Mr. Smith of Deanstone has invented one made entirely of iron, and Sir E. Stracey has constructed another with a small wheel in front very strongly put together, although the beam is of wood. It is of somewhat lighter draught than Mr. Smith's, but it does not go quite so deep. This plough requires four horses in the most favourable soils, and six in tenacious clays, to keep up with the common plough, which always should precede it. Sometimes however the subsoil-plough may be used alone, where the surface is already mellow and crumbling. The figure of each of these ploughs, which is subjoined, requires little explanation when the purpose for which they are used is understood

Fig. 21.



Smith's Subsoil Plough.

Fig. 22.

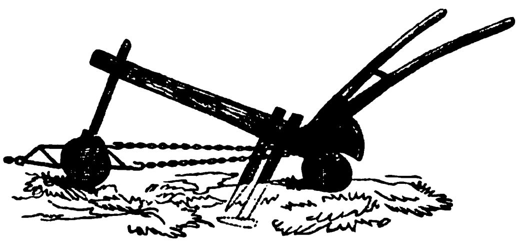


Stracey's Rackheath Plough.

Many different ploughs have been invented for the purpose of saving labour in draining land. As they all cut out a slice from the bottom of a furrow and raise it up to the surface of the ground, they are of little use in crumbling soils, and in the most tenacious require the assistance of much manual labour to complete the work. They act on the principle of the carpenter's tool by which a groove is formed in the edge of planks or deals, when they are intended to be joined closely as in a floor. This instrument is also called a plough; but the uniform tenacity of the wood allows a narrow chisel to cut an even regular groove. In the draining-plough the two sides of the drain are to be cut obliquely downwards and the bottom scooped out evenly. The plough requires to be often adjusted, and the deep furrows to be kept cleared from loose earth by means of spades and scoops. In this way drains may be made from 15 to 18 inches deep, in which loose stones or tiles may be laid to form a channel for the water. The expense is much less than when the drains are made with the spade.

When grass-land lies low and wet on a very tenacious subsoil, a plough is sometimes used which consists of a cylinder of iron pointed at one end, and connected with a strong beam by a thick plate of iron, which is sharp on the side nearest the point of the cylinder, and acts as a coulter. This instrument is forcibly drawn horizontally through the stiff subsoil at a depth of 12 to 18 inches, so as to leave a round channel like a pipe where the cylinder has passed. This has been called a mole-plough, the passage made by it under ground resembling the workings of a mole. It takes six horses to draw this plough, when the cylinder is 15 inches under the surface, but it is the most easy and expeditious means of temporarily draining land. It can only be done when the soil is moist and gives way without cracking, but at that time the feet of the horses greatly damage the surface. In consequence of this a windlass with a long chain has been invented. The drum, which is vertical, and round which the chain is coiled, is turned by a horse who walks round and round, while the whole apparatus is kept in its place by means of an anchor fixed in the ground. It draws the mole-plough the length of the chain, and is then moved forward on small wheels while the chain uncoils. As soon as the chain is all off the drum, the anchor is refixed and the operation continues. This mode of draining land has now been almost entirely superseded by a more regular and permanent system of draining with stones or tiles. The channels made by the mole-plough are very apt to fill up in dry weather; and the mole takes advantage of a ready-made passage to work in it, stopping it purposely to retain water and to form its nest. When this is the case, the water springs to the surface and does much harm. Nothing but a fresh application of the mole-plough parallel to the old channels can remedy this evil.

Fig 23.



Lumbert's Mole Plough.

Various ploughs have been constructed with the intention of diminishing the draught, or improving the form of the turn-furrow; but most of them, without much regard to scientific principles, merely from a vague notion founded on some real or supposed defect in the ploughs in common use, or in order to adapt them to particular soils and situation. It would be useless to take notice of many of them, which have but little merit, and are not generally approved of. At the meeting of the Royal Agricultural Society at Cambridge in 1840, Messrs. Ransom, of Ipswich, exhibited no less than eighty-two differently constructed ploughs, giving an excellent opportunity to those who wished to compare the principles on which they are constructed, and the manner in which these principles are applied.

PLOUGH-MONDAY, the Monday next after Twelfth Day, fixed upon by our forefathers as the period when the labours of the plough and other rustic toils begin. In Derbyshire, and in some of the northern counties, the young men formerly used to yoke themselves and draw a plough about with music on this day; one or two persons, disguised in antic dresses, like jack-puddings, accompanying them, and going from door to door, soliciting plough-money to provide drink. In some places it was a custom, if the ploughman, after that day's work, came with his whip to the kitchen hatch, and cried 'Cock in the pot,' before the maid could cry 'Cock on the dunghill,' he gained a cock for Shrove-Tuesday. Tusser, in his 'Five Hundred Points of Husbandry,' mentions Plough-Monday among the ploughman's feast-days.

(Brand's *Popular Antiq.*, 4to., 1813, vol. i., pp. 396, 397; Brady's *Clavis Calendaria*, 8vo., 1812, vol. i., pp. 151, 152; *Lady's Dictionary*, by N. B., 8vo., Lond., 1694, p. 377.)

PLOVERS, CHARA'DRIADÆ, a family of birds placed by Mr. Vigors in the order *Grallatores*, or *Waders*. The genus *Charadrius*, including the *true Plovers, the Dotterell, the Sea-Lark, the Sanderling, the Stone Curlew* (*Œdic-*

nemus), *the Long-legged Plover* (*Himantopus*), and the *Spur-winged Plover* (*Charadrius Spinosus*), was placed by Linnæus, in his *Systema Naturæ*, between the genera *Tringa* and *Recurvirostra* [Avoset], in his order *Grallæ*.

Cuvier makes the family of Plovers (*Les Pluviers*, *Charadrius*, Linn.), comprising those genera which want the hind-toe, and have a moderate bill compressed and convex at the end, consist of two genera, *Œdicnemus*, and the Plovers properly so called (*Charadrius*, Linn.), embracing the *Golden Plover*, *Charadrii Morinellus*, *Hiaticula*, &c. The Plovers are succeeded by the *Vanneaux* (*Vanellus*, Bechst., *Tringa*, Linn.), consisting of *Squatarola*, Cuv., and *Vanellus*, Cuv.; which are followed by *Hæmatopus* and *Cursorius*; after which last, judging from external form, he places the Cariama (*Microdactylus*, Geoff., *Dicholopus*, Ill.). [Cariama.]

Mr. Vigors is of opinion that we are introduced to this family by means of *Hæmatopus*, Linn., which indicates its affinity to the lobated *Fulica* of the preceding family *Rallidæ* by the rudiments of the membrane that extends along the toe. This character, he observes, is sufficiently discernible in the species so frequent on our coasts [Sea Pie]; but it is so far conspicuous in an Australasian species as almost to give its foot the appearance of being perfectly lobated. This genus, he remarks, by its habits of swimming, preserves an affinity with the natatorial groups of the *Rallidæ*; and these again being connected with *Phalaropus*, which forms, in Mr. Vigors's arrangement, the extreme genus of the *Scolopacidæ*, the whole of the *Wading Birds* that possess the faculty of swimming are brought together into one contiguous group. Besides *Hæmatopus*, the *Charadriadæ* of Mr. Vigors consist of *Arenaria*, Briss., our common Sanderling; to which he feels inclined to add *Strepsilus*, Ill., and *Vanellus*, Briss., which have been separated from *Tringa* and generally assigned a place near *Arenaria*. Mr. Vigors observes that it is true that both these genera possess a hind toe; but that member, he adds, is at the same time so small and feeble as scarcely to form more than a rudiment; and in the structure of their bill, and more particularly in their habits, they evince a more natural union with the *Charadriadæ* than with *Tringa*, where a strict adherence to the structure of the foot would place them. The genus *Cursorius*, Lath., also appears to Mr. Vigors to come among these groups, which are joined by the true *Charadrius* of authors. Among the numerous species of this latter genus he notices some that are distinguished from the rest by the greater elevation of the *tarsi*. These, in his opinion, lead us to the genus *Himantopus*, Briss., which exhibits such a singular and apparently disproportioned length of limb. The family is terminated, according to the theory of Mr. Vigors, by the *Œdicnemus* of Cuvier [Œdicnemus], which, by its affinity with the earlier groups of the *Gruidæ*, connects, in his view, the present family with that (*Gruidæ*) which commenced the order *Grallatores*. He reminds the reader that the family of *Struthionidæ* among the *Rasores* is closely allied to the *Gruidæ* and equally so to the *Charadriadæ*, in consequence of the absence of the hinder toe. With the latter, indeed, he observes, it is frequently united into one group, from their similarity in this character, and the cursorial habits resulting from it, which are common to both. These three naturally allied families therefore are thus, in Mr. Vigors's opinion, brought into contact, and their mutual affinity preserved; while at the same time they retain in the system the various stations into which the difference in their more important characters tends to separate them. (*Natural Affinities that connect the Orders and Families of Birds*, in *Linn. Trans.*, vol. xiv.)

M. Lesson makes the family *Charadriadæ*, Leach, consist of *Ostralega*, Briss.; *Calidris*, Ill.; *Erolia*, Vieill.; *Cursorius*, Lath.; *Strepsilas*, Ill.; *Squatarola*, Cuv.; *Vanellus*, Briss.; *Pluvianus*, Vieill.; *Charadrius*, Linn.; *Burhinus*, Ill.; *Œdicnemus*, Cuv.; and *Himantopus*, Briss. (*Manuel*.)

The *Charadriadæ*, or Plovers, are considered by Mr. Swainson to form the subtypical family of the order *Grallatores*, and they seem to him to be connected to the *Ardeidæ* through the medium of the Cranes, the Thick-knees (*Œdicnemus*), or probably by the genus *Cariama*,—a form, by the way, which Mr. Swainson admits that he has never minutely examined. He observes that in this comprehensive group the feet are long and slender, formed for great speed, the toes short, and the hinder one generally wanting, the wings long, and the powers of flight consequently great. 'Herons and Rails,' says he, 'seek the most secluded recesses of marshy shades. Plovers and Sandpipers, on the contrary, live only on sandy and unsheltered shores, or on exposed commons; they congregate in flocks, and run with great swiftness; their heads are thick, and their eyes large, dark, and placed far back in the head; the bill is short, with the basal half soft, but the outer half becomes abruptly thick, and is often obsoletely notched, so as closely to resemble that of the pigeon family, which, in the Rasorial circle, appears to represent the great order of Waders. The following genera are the most prominent types:—The Oystercatchers are rather large and strong birds, marked with black and white; and their principal food is supposed to be oysters and other shell-fish. One species alone belongs to Europe, the others are natives of South America and Australia. The Turnstone (*Strepsilas*) is at once recognised by a short stout bill, rather turned upwards: the name is derived from the habit it possesses of turning up stones on the sea-shore, to feed upon the marine insects[*] concealed beneath. The Couriers (*Tachydromus*, Ill.), although confined to the Old World, seem to be very widely distributed· one species occasionally visits Europe, and has twice[†] been shot in England;[‡] the others, four or five in number, come from the African deserts and the sandy districts of India [Cursorius]; they are closely united to the *Pratincoles*, or Swallow-Plovers, forming the genus *Glareola*. These latter have their wings very long, their bills short, and their tails generally forked; they are small birds, and fly with great celerity. Our beautiful Lapwing forms a typical example of the subgenus *Vanellus*. The true Plovers (*Charadrius*) form a numerous group, very elegantly although not richly coloured, and dispersed, with little or no variation of form, over the whole world. The feet, as in the Spur-winged Plovers, are only three-toed, and the wings are much pointed; sometimes there is a slight membrane between the outer and the middle toe, but this is usually wanting. We have two elegant little species on the British coast, and some others occur in Southern Europe. The Longshanks (*Himantopus*) have been placed in this group, but we believe they belong to the *Tringidæ*: whatever their true station may be, they are certainly some of the most singular birds in the family; and by the excessive length of their legs, they no doubt represent the Flamingoes: we know but of three species. At the end, or rather at the commencement of this group, we may place the thick-kneed Bustards (*Œdicnemus*); since they are obviously allied to the *Charadriadæ*, or Plovers, on one side, and to the *Ardeidæ* by means of the aberrant Cranes on the other. All the species have been hitherto confined to the Old World; but another, described in this volume, has recently been discovered in the interior of Tropical America. These birds, while they exhibit a strong affinity to the typical Plovers, have many points of resemblance to the Cranes; so that we can agree with Mr. Vigors in considering *Œdicnemus* to have an affinity with the earlier groups of the *Gruidæ*, forming part of our *Ardeidæ*; and that they thus connect the present family with that.' (*Classification of Birds*.)

Mr. Swainson thus characterises the family:—

Bill short; the basal half soft, the remaining portion hard; the culmen suddenly elevated and curved. Nasal groove deep, extending to half the length of the bill. Feet long. The three anterior toes cylindrical; the hinder generally wanting. This family is placed by Mr. Swainson, in the *Synopsis* at the end of the volume above referred to, as the last of the order *Grallatores*, and embraces the following genera and subgenera:—

Squatarola, *Charadrius*, *Vanellus*, *Œdicnemus*, *Tachydromus*, *Glareola*, and *Ammoptila*.

The Prince of Musignano (C. L. Bonaparte) makes the '*Charadridæ*' the first family of the order *Grallæ*, Linn., and he comprises within it the genera *Otis*, *Œdicnemus*, *Cursorius*, *Glareola*, *Ægialites* (Boie), *Eudromias* (Boie), *Charadrius*, *Squatarola*, *Vanellus*, *Hoplopterus* (Bonap.), *Strepsilas*, and *Hæmatopus*. It must be remembered that the *List of Genera*, which gives this arrangement, applies to the Birds of Europe and North America only.

The first family of the order *Grallatores*, according to Mr. G. R. Gray's arrangement, is the *Charadriadæ*, which are divided by him into the following subfamilies and genera:—

[*] Crustacea ?

Thrice.

[‡] And once in North Wales.

Subfamily 1. *Œdicneminæ.*

Genera. *Œdicnemus*, Temm. (*Charadrius*, Linn.; *Otis*, Lath; *Pluvialis*, Briss.).

Burhinus, Ill. (*Œdicnemus*, Shaw; *Charadrius*, Lath.).

Subfamily 2. *Cursoriinæ.*

Genera. *Cursorius*, Lath. (*Charadrius*, Gm.; *Tachydromus*, Ill.); *Oreophilus*, Gould.

Ortygodes, Vieill. (*Hemipodius*, Sw.; *Ortygis*, Steph.).

Pluvianus, Vieill. (*Charadrius*, Gm.; *Cursor*, Wagl.; *Hyas*, Gloger; *Ammoptila*, Sw.; *Cheilodromus*, Rüpp.).

Subfamily 3. *Charadrianæ.*

Genera. *Glareola*, Briss. (*Hirundo*, Linn.; *Trachelia*, Scop.).

Squatarola, Cuv. (*Tringa*, Gm.; *Pluvialis*, Briss.; *Vanellus*, Bechst.; *Charadrius*, Pall.).

Vanellus, Briss. (*Tringa*, Linn.; *Charadrius*, Wagl.; *Gavia*, Klein).

Erythrogonys, Gould

Philomachus, Mœhr. (*Parra*, Gm.; *Vanellus*, Gm.; *Hoplopterus*, Bonap.).

Charadrius, Linn. (*Pluvialis*, Ray).

Eudromias, Boie (*Charadrius*, Linn.; *Pluvialis*, Briss.; *Morinellus*, Gesn.).

Hiaticula, Mœhr. (*Charadrius*, Linn.; *Pluvialis*, Briss.; *Ægialites*, Boie).

Pipis, Licht. (*Charadrius*, Licht.).

Anarhynchus, Quoy and Gaim. (*Scolopax?* Raffles).

Subfamily 4. *Hæmatopinæ.*

Genus. *Hæmatopus*, Linn. (*Ostralega*, Briss.; *Scolopax*, Scop.).

Subfamily 5. *Dromadinæ.*

Genera. *Dromas*, Payk. (*Erodia*, Stanley; *Corrira*, Briss.?)

Esacus, Less. (*Carvanaca*, Hodgs.).

We now proceed to the consideration of some of the forms included in this family.

Charadrius. (Linn.)

Generic Character.—Bill slender, straight, compressed, shorter than the head; nasal furrow prolonged more than two-thirds; mandibles enlarged towards the tip. Nostrils basal, jagged, cleft longitudinally in the middle of a large membrane which covers the nasal fossa. Toes three, directed forwards, the external united to the middle one by a short membrane; the inner toe free. Tail square or slightly rounded. Wings moderate, first quill-feather longest. (Gould.)

Head and foot of Charadrius.

Example, *Charadrius pluvialis*, Linn.

Description.—Old Male in winter plumage.—Top of the head, as well as all the upper parts of the body, wings, and tail, sooty black, marked with large spots of golden yellow, disposed on the borders of the barbs of the feathers; sides of the head, neck, and breast varied with ashy brown and yellowish spots; throat and lower parts white; quills black, shafts white towards the end; bill blackish; feet deep ash-colour; iris brown. Length rather more than ten inches.

Female.—Differing hardly at all from the male.

Young of the year.—Upper parts ashy black with spots of yellowish ash. (Temm.)

In this garb, the birds are, according to Temminck, *Charadrius pluvialis*, Gm.; *Charadrius auratus*, Suckow.; *Le Pluvier doré*, Buff.; *Golden or Green Plover*, Lath.; *Goldregenpfeifer*, Bechst.; *Piviere dorato*, of the *Stor. degl. Ucc.*; *Goud Plevier*, Sepp.

Old Male and Female in summer or nuptial plumage.—Upper parts deep black; over all the borders of the feathers are disposed small spots of a very bright golden yellow; front and space above the eyes pure white; lateral parts of the neck white also, but varied with great black and yellow spots; throat, front of the neck, and all the other ower parts deep black.

Periodical variation during the moult.—White and black mingled are often seen on the lower parts of the feathers. This livery is always to be seen on the young birds, even after their first spring moult. (Temm.)

In this state the bird is, according to M. Temminck, *Charadrius apricarius*, Gmel.; *Le Pluvier doré à Gorge noire*, Buff.; *Alwargrim Plover*, Lath.

In the fourth part of his 'Manuel,' just published, M. Temminck adds the following synonyms: *Charadrius auratus*, Naum.; *Der Platköpfige, Hochsternige, Mittlere, und Hochköpfige Goldregenpfeifer*, Brehm.; *Brockfogel*, Nils.; and *Piviere*, Savi.

This species is also *Le Pluvier Guillemot* of Belon (who says that it is named *Pluvier*, 'pour ce qu'on le prend mieux en temps pluvieux qu'en nulle autre saison,' and he gives an amusing account of the mode of taking these birds by the peasants); *Der Rechte Brachvogel* of the Germans; *Hawk's Eyes* of the Hudson's Bay residents?; *Cwttyn yr aur* of the antient British.

Habits, Food, Reproduction, &c.—Mr. Selby gives a most correct and interesting account of the habits of the bird in this country:—'About the end of May or beginning of June, the females begin to lay, making but little artificial nest, a small depression in the ground amidst the heath being generally taken advantage of, and lined with a few dry fibres and stems of grass. The eggs are four in number, rather larger than those of the lapwing, of a cream-yellow inclining to oil-green, with large irregular confluent blotches or spots of deep umber brown. The young, when excluded, are covered with a beautiful particoloured down of bright king's yellow and brown; they quit the nest as soon as hatched, and follow their parents till able to fly and support themselves, which is in the course of a month or five weeks. The old birds display great anxiety in protecting their young brood, using various stratagems to divert the attention of an enemy; among others, that of tumbling over, as if unable to fly, or feigning lameness, is most frequent, and appears indeed to be the instinctive resort of those birds that construct the nest and rear their young on the ground. When aware of an intruder near, the female invariably runs to some distance from her nest before she takes wing, a manœuvre tending to conceal its true situation; and the discovery of it is rendered still more difficult by the colour and markings of the eggs assimilating so closely to that of the ground and surrounding herbage. The usual call-note of the Plover is a plaintive monotonous whistle, by imitating which it may frequently be enticed within a very short distance. In the breeding season a more varied call is used, during which it flies at a great elevation, and continues soaring round for a considerable time. Towards the end of August these birds begin to leave the moors (having there congregated in large flocks), and descend to the fallows and the newly-sown wheat-fields, where an abundance of their favourite food can be readily obtained. At this season they soon become very fat, and are excellent at the table, their flesh not being inferior in flavour to that of the Woodcock or any of our most esteemed sorts of game. In these haunts they continue till severe weather approaches, when they either move nearer to the coast or migrate to the southern parts of the kingdom. They fly with strength and swiftness, and if disturbed, when in large flocks, generally perform many aerial evolutions and rapid wheelings before they again settle on the ground. The Golden Plover is a nocturnal feeder, and, during the day, is commonly seen squatted upon the ground or standing asleep, with the head drawn down between the shoulders. Its food consists of earth-worms, slugs, insects, and their larvæ, particularly those of the *Lepidopterous* tribe, many rare species of which I have, upon dissection, found in their stomachs and gullet during the summer season. It runs very fast, and, when wounded, is difficult to be caught without the aid of a dog.'

Utility to Man.—This species has been always considered, and most justly, a delicious dish. It figures in the old bills of fare accordingly. Thus in the account of Sir John Nevile, of Chete Knight, of the viands, &c., used at the marriage of his son-in-law Roger Rockley and his daughter Elizabeth Nevile, the 14th of January, in the seventeenth year 'of the reigne of our soveraigne lord king Henry VIII.' we find in the second course, 'Item, plover, 8 of a dish' and among the charges, 'Item, in plover, 3 doz., 5*s*.' In the charge of the said Sir John Nevile, at Lammas Assizes, twentieth of Henry VIII., we also find 'Item, 6 doz. plovers, 12*s*.' Four hundred plovers appear among 'the goodly provision' at the intronazation of George Nevell, archbishop of York, in the reign of Edward IV. Drayton, in his 'Polyolbion,' makes *Lyndsey* boast that her 'fowle' 'more ayrie are' than those of *Holland* (Lincolnshire):

> 'And make fine spirits and blood,
> For neere this batning isle, in me is to be seene,
> More than on any earth, the plover grey and greene.'

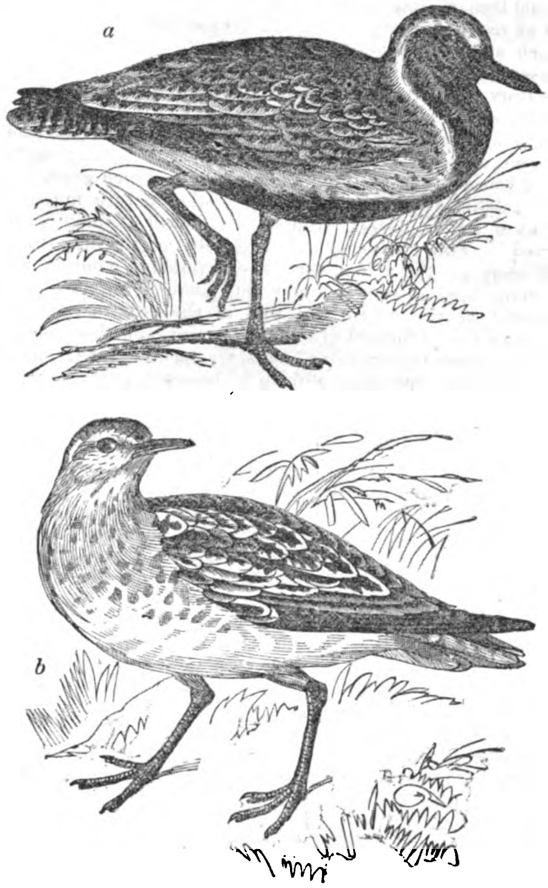
Geographical Distribution.—Very wide. There is evidence of the presence of the *Golden Plover* in each of the four quarters of the globe. Mr. Gould indeed, in his observations on the geographical distribution of the species collected by Mr. Keith Abbot in the neighbourhood of Trebizond, notices the bird as inhabiting Europe, and the adjoining portions of Africa and Asia, but not America. (*Zool. Proc.*, 1834.) Now Temminck expressly says that the species is the same in America and Asia. Sabine also (Parry's *First Voyage*) makes Wilson's *Charadrius apricarius* and the *Golden Plover* identical, and states that it breeds in the swampy parts of the North Georgian Islands in considerable abundance. Richardson states that the breeding-quarters of this well-known bird are the barren grounds and the coasts and islands of the Arctic Sea. 'It hatches,' he says, 'early in June, and retires southward in August. Numbers linger on the muddy shores of Hudson's Bay, and on the sandy beaches of rivers and lakes in the interior, until the hard frosts of September and October drive them away. At this period they are very fat, and are highly prized by the epicures of the fur countries. They make but a short stay in Pennsylvania, and are said to winter beyond the United States.' (*Fauna Boreali-Americana.*)

Captain James Ross, R.N., notices it as abundant during the breeding season in most parts of the arctic regions, and he found them plentifully in the neighbourhood of Felix Harbour, feeding in the marshes, in company with *Charadrius semipalmatus* (American Ring Plover). (Sir John Ross's *Second Voyage.*) Nuttall remarks that the bird is, according to the season of the year, met with in almost every part of the world, particularly in Asia and Europe, from Kamtschatka to China, as well as in the South Sea Islands, and from Arctic America, where it breeds, to the Falkland Islands. The Prince of Musignano (*Birds of Europe and North America*) appears, on the other hand, to agree with Mr. Gould, for the Prince makes the American analogue of *Charadrius Pluvialis*, Linn., *Charadrius Virginiacus*, Borkh. (*Charadrius Pluvialis*, Wils.), and Colonel Sykes notes it among the birds of the Deccan, and as identical with Javanese specimens, smaller indeed than one North American specimen and two English specimens in the British Museum, but absolutely identical with other British specimens. He says that it is rare in 'Dukhun,' and appears only in the cold weather. In the stomach he found beetles, land-insects, and coarse sand. (*Zool. Proc.*, 1832.) It appears among the list of birds seen in Japan by Dr. Von Siebold and M. Bürger; and Temminck states that those killed there did not differ essentially from those of Europe. Mr. Selby allows a wide geographical range to it, though not to the extent supposed by many naturalists, the birds which have been considered by them as belonging to this species being of a different one, viz. *Char. marmoratus* of Wagler. Instead therefore of extending the range of the Golden Plover to America, New Holland, and other parts of the southern hemisphere, he feels inclined to limit it to Europe, Northern Asia, and some few districts in the North of Africa. (*British Ornithology.*)

Eudromias, Boie; (Morinellus, Gesn.)

Example, *Charadrius Morinellus*, Linn.; *Eudromias Morinella*, Boie; *Eudromias Morinella montana et stolida*, Brehm, according to Temm.

Description.—(*Winter Plumage.*)—Top of the head and occiput blackish-ash; large eyebrows of reddish-white uniting on the occiput; face white, dotted with black; upper parts blackish-ash tinged with greenish, all the feathers of those parts framed as it were with ruddy colour; breast and sides reddish-ash; the large patch on the breast and the middle of the belly pure white; shaft of the first quill white, except towards the end, tail terminated with white; bill black; iris brown; feet greenish-ash. Length more than 8 inches.



Charadrius Pluvialis, Golden Plover.
a, Summer dress; *b*. Winter dress.

The *young* have the tints more ashy; top of the head reddish or rusty, varied with longitudinal spots; the ruddy colour which frames as it were the feathers of the upper parts less vivid; tail terminated with bright ruddy.

Summer or nuptial plumage.—Very old Male.—Face and eyebrows very pure white; summit of the head and occiput blackish; nape and sides of the neck ashy; feathers of the mantle and wings bordered with very deep ruddy; on the breast a narrow brown band, succeeded by a large white cincture; part below the breast and sides very bright ruddy; middle of the belly deep black; abdomen reddish-white.

Female.—Ruddy colour of the sides often clouded with ash-colour; black spot of the middle of the belly less apparent than in the male or varied with white feathers.

N.B.—During the moult the plumage varies considerably in different individuals. (Temm.)

This is the *Pluvier Guignard* and *Pluvier solitaire* of the French; *Piviere de corrione* and *Piviere tortolino* of the Italians; *Der Dumme Regenpfeifer* of the Germans; *Dotterel*, *Dotterell*, and *Dottrell* of the modern British, and *Huttan* of the antient British.

Habits, Food, Reproduction, &c.—Drayton sings, of this bird—

> The Dotterell, which we think a very dainty dish,
> Whose taking makes such sport as man no more can wish;
> For as you creepe, or cowre, or lye, or stoupe, or goe,
> So marking you (with care) the apish bird doth doe,
> And acting everything, doth never mark the net,
> Till he be in the snare which men for him have set.'

Poets have a right to a little licence, and in many of the older prose writers a similar account of the silly mimicry of the bird is given. 'The Dotterel,' says Mr. Selby, 'has always been considered a stupid bird, but for what reason I cannot conceive. I allow that, on its first arrival, it shows but little fear of man, but this, I apprehend, arises more from inexperience of persecution in its native wilds, than from any other cause, and which appears evident from the birds, when harassed and repeatedly fired at, soon becoming too cautious to admit of near approach any longer. Their habits also contribute to render them unwary, for being nocturnal feeders (like many others of the *Charadriadæ*), they are at rest and asleep during the greater part of the day, in which state also the *Golden Plover* (a wary bird when roused) will frequently admit of a close approach. As to the story of the Dotterel mimicking the actions of the fowler, by stretching out its leg, wing, or head, when he sets the example, it, without doubt, arose from the motions that they as well as other birds usually and most naturally make when roused from a state of repose; and which every one who attends to the habits of the feathered race must (in flocks of gulls, plovers, tringas, &c.) have frequently observed.' The food consists principally of insects, slugs, and worms. For a long time it was doubted whether the Dotterel bred in this country, but these doubts are now removed, as the reader will find in the next paragraph. The rude nest is formed of lichens or moss, and the three or four lustreless olive-coloured eggs are sprinkled with large dots and numerous spots of deep brown-olive.

Geographical Distribution.—Mr. Selby notices the Dotterel as particularly abundant in Northern Asia and the eastern parts of Europe, and as inhabiting Siberia and the vast steppes of Tartary, frequently living in the vicinity of the salt lakes and marshes of that open region. He adds, that it is also found, during its winter migration, in Italy and Spain, and that the great body of these birds retires to the high latitudes of Northern Asia, Russia, and Lapland Alps to breed; but the flocks which pass along the eastern coast of our island are supposed to limit their flight to the upland districts and mountains of Sweden and Norway. Temminck states that it breeds in the north of Russia. Also in Norway on the great bare plateaux of the mountains, and, in no great number, on the high mountains of Bohemia and Silesia, at an elevation of from 4500 to 4800 feet. In this country, Sussex, Hampshire, Wiltshire, Berkshire, Cambridgeshire, Lincolnshire, Derbyshire, Yorkshire, and Northumberland possess it. Dr. Latham states that in the elevated district of Braemar, Aberdeenshire, these birds hatch their young on dry mossy ground near to and on the very summits of the highest parts, sometimes in the tufts of little short heather or moss. The female sits three weeks, and the young appear about the middle of July. Mr. Yarrell exhibited eggs of this bird, belonging to Mr. Heysham of Carlisle, obtained on Skiddaw in the summer of 1835. Several pairs were breeding in the same locality. (*Zool. Proc.* 1836.) Mr. Gould (*Birds of Europe*) says 'the eggs of these birds are so difficult to obtain, that we only know one collector who possesses them. They are one inch eight lines long, by one inch two lines and a half in breadth, light olive-brown blotched and spotted with black: these specimens were procured from the Grampian Hills.'

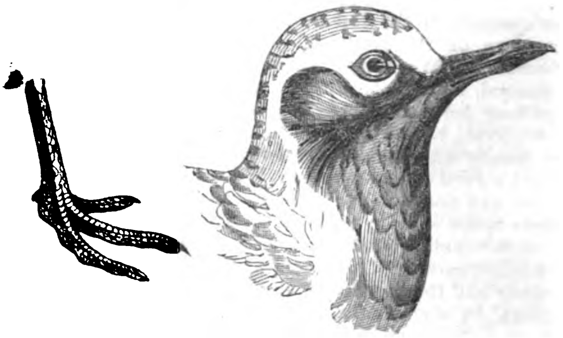
Utility to Man.—Excellent for the table when in season. Numbers are shot near Cambridge and Royston during their spring migration. We find 'Dotrels' charged at one penny each, a considerable sum in those days, in the *Northumberland Household-Book*, and enumerated among the birds admitted to the high (his Lordship's) table. They now find a ready sale in the London market at about six shillings a couple.

Dottrell in nuptial plumage.

That pretty little Plover, *The Ring Dottrell*, comes under the genus *Hiaticula*, Mœhr.

Squatarola. (Cuv.)

Generic Character.—*Bill* rather strong, cylindrical, straight, nearly as long as the head; the tip or horny part, about half the length of the whole bill, tumid and arched with the *tomia* bending inwards. *Nasal groove* wide, half the length of the bill. *Mesorhinium* depressed below the level of the tip. *Nostrils* longitudinally pierced in the membrane of the groove, linear, oblong. *Wings* rather long, acuminate, with the first quill-feather the longest. *Legs* slender, of mean length, naked above the tarsal joint. *Feet* four-toed, three before and one behind; front toes joined at their base by a membrane, that portion of it between the outer and middle toe being the longest; hind toe very small or rudimental. *Tarsi* reticulated. Plumage thick, close, and adpressed. (Gould.)



Head and Foot of Squatarola.

Example, *Squatarola cinerea* (*Tringa Squatarola*, Linn.), the *Bastard* or *Grey Plover*.

Description.—*Adult Male and Female, winter plumage.*—Front, throat, middle of the belly, thigh, abdomen, and upper coverts of the tail pure white; space above the eye, front of the neck, sides of the breast and sides white varied with brown and ashy spots; upper parts blackish-brown, variegated with greenish-yellow spots, but the whole of the feathers terminated with ash-colour and whitish; long internal feathers of the wings deep black; lower coverts of the tail marked on their external barbs with small diagonal brown bands; tail white but reddish towards the end, striped with brown bands, which are pale and few, and placed on the lateral feathers; bill black; iris blackish; feet ashy-black. Length rather more than 10 inches.

Adult Male and Female, in their spring or nuptial plumage.—Space between the eye and the bill, throat, sides and front of the neck, middle of the breast, belly, and sides deep black; front, a large band above the eyes, lateral parts of the neck, side of the breast, thighs, and abdomen pure white; nape variegated with brown, black, and white; occiput, back, scapulars, and coverts of the wings deep black; all the feathers of these parts terminated by a large space of pure white; large white spots on the greatest of the wing-coverts and on the scapulars; oblique black bands on the lower tail-coverts; feathers of the middle of the tail striped with white and black.

The Young before the moult resemble more or less the adult birds and the young in winter; the front, space above the eye, sides of the neck, and sides are variegated with larger but paler spots; upper parts of a bright grey tint varied with whitish; also a little whitish at the extremity of the quills; transverse bands of the tail grey. (Temm.)

In the first of these states of plumage the bird is the *Tringa Squatarola*, Gmel.; *Le Vanneau Varié*, Buff.; and *Grey Sandpiper*, Lath. (*Syn.*)

In the second it is the *Vanellus melanogaster*, Bechst.; *Tringa Helvetica*, Gmel.; *Charadrius apricarius*, Wils.; *Le Vanneau Suisse*, Buff.; *Swiss Sandpiper*, Lath.; and *Schwarzbauchiger Kiebiz*, Meyer.

The young before the moult are *Tringa Squatarola, var.*, Gmel.; *Le Vanneau Pluvier*, and *Vanneau Gris*, Buff.; *Grey Sandpiper*, Lath.; and *Schwarzbauchiger Kiebiz, im Herbstkleide*, Meyer.

M. Temminck, who gives these synonyms, remarks, in his 'Manuel,' that at the two epochs of the moult, individuals are found which have the deep black of the lower parts sprinkled with some white feathers, or, when the white predominates, it is variegated with some black feathers. The birds in winter plumage and the young may, he observes, be easily distinguished from those of the *Golden Plover*, first, by the presence of the posterior toe; and, secondly, by the long black feathers which are found inside of the wings near the body; the rest of the plumage differs so little at these epochs, that one might be easily mistaken.

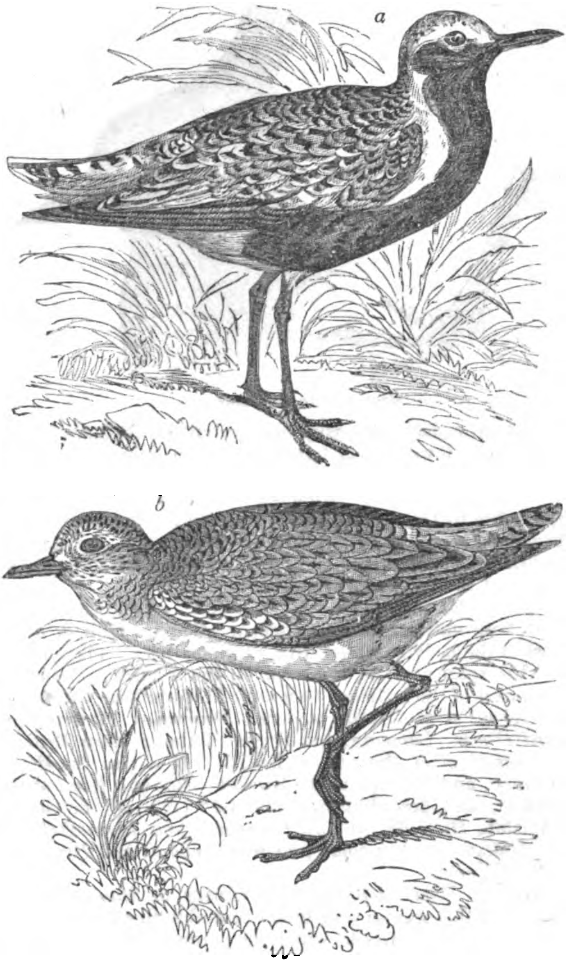
This species is the *Charadrius hypomelas* of Wagler, and the *Grey Squatarole* of Shaw. It appears to be the *Pluvier Gris* of Belon, and in the 'Portraits d'Oyseaux,' &c., is the following loyal quatrain under the figure of the bird:—

> 'De nuict seulet, de jour en compagnie,
> Va le Pluvier suyvant son appelleur.
> Par la voit-on, que c'est bien le meilleur,
> Qu'une gent soit par un Roy gouvernée.'

M. Temminck, who, in the fourth part of his 'Manuel' (1840), protests against the generic separation of this form, not without a passing but sweeping censure on 'toutes les autres coupes nouvelles,' adds to the synonyms *Squatarola varia et Helvetica*, Brehm.; *Kiebiz Regenpfeifer*, Naum.; *Pivieressa*, Savi; and *Sprackling Vipa*, Nils.

Habits, Reproduction, &c.—In Britain, where it is not numerous, and principally known as a migratory species, it is found on the coast 'in oozy bays, or at the mouths of rivers,' where it feeds upon worms, marine crustaceans, &c. The bird runs well, and its whistle is like that of the Golden Plover, but not so shrill. If killed in good season it is delicious for the table. The nest is of the most rude construction. A shallow depression in the earth is lined with a few pieces of dried bents or straw, and there four eggs generally, which are oil-green blotched with black, are deposited. According to Wilson and Nuttall, this Plover has often in the temperate parts of the United States two broods in a season, though it has only one in Massachusetts, where their nests are of rare occurrence. During the summer both young and old feed much upon various kinds of berries, particularly those of the early bramble, called dew-berries, and their flesh is then highly esteemed. About the last week in August they repair with their young to the borders of the sea-coast, where they assemble in great numbers, feeding on small shell-fish, shrimps, and other small marine animals. Grasshoppers and other insects that abound in the fields are also eaten by them. 'They are,' says Nuttall, 'extremely shy and watchful, uttering a loud rather plaintive whistling note as they fly high and circling in the air, and are so often noisy, particularly in the breeding season, as to have acquired among many of the gunners along the coast the name of the *Black-Bellied Killdeer*. They usually linger round the sea-coast in the Middle States till the commencement of November, when the frosts beginning sensibly to diminish their prospect of subsistence, they instinctively move off towards the south, proceeding probably at this time under the shade of twilight, as moving flocks are nowhere, as far as I can learn, seen by day. About the middle of September, in the marshes of Chelsea (Mass.) contiguous to the beach, they sometimes assemble at day-break in flocks of more than a thousand individuals together, and soon after disperse themselves in companies on the shores, to feed upon the small shell-fish and marine insects (crustacea). This crowding instinct takes place a short time previous to their general migration southward.' (*Manual of the Ornithology of the United States and Canada.*)

Geographical Distribution.—All the temperate countries of Europe. More abundant in France than in Germany; rare in Switzerland; common enough in the islands and on the coasts of Holland. Abundant in summer in the regions of the Arctic Circle and of Oriental climates, where it breeds. M. Cantraine killed a young one in the Strait of Boniface. (Temm.) Dr. von Siebold and M. Bürger saw it in Japan, and M. Temminck states that he has seen individuals from that locality in both summer and winter plumage. Dr. Richardson, who notices it as the *Toolee-areeoo*, or *Tooglee-aiah* of the Esquimaux, says that it is observed in the fur countries in similar places to those frequented by the Golden Plover, though it is not equally common, and that it breeds in open grounds from Pennsylvania to the northern extremity of the continent. He describes a specimen, killed at Hudson's Bay, lat. 57°, in August, 1822. Captain James Ross, in the Appendix to Sir John Ross's *Last Voyage*, observes that it was more rarely met with than the Golden Plover, but was found breeding near the margins of the marshes immediately to the south-west of Fury Point, in considerable numbers. Some specimens were also obtained near Felix Harbour. It is met with in Egypt and upon the confines of Asia, in Siberia, &c. (Selby.) The last-quoted author states that in Northumberland there are a few stations on the coast of Britain, where it is found during the whole winter, but only in families or small flocks. It generally arrives about the middle of September, sometimes even earlier, he adds, at which time several of the old birds still retain a part of their summer plumage. In the month of May they go northward. Mr. Gould says that they appear in the greatest abundance in this country while performing their periodical migrations in the months of April and May along the coasts of Lincolnshire, Norfolk, Suffolk, Essex, and Kent. (*Birds of Europe.*)



Squatarola cinerea—Grey Plover, or Grey Lapwing.
a, spring plumage; *b*, winter plumage.

Vanellus. (Briss.)

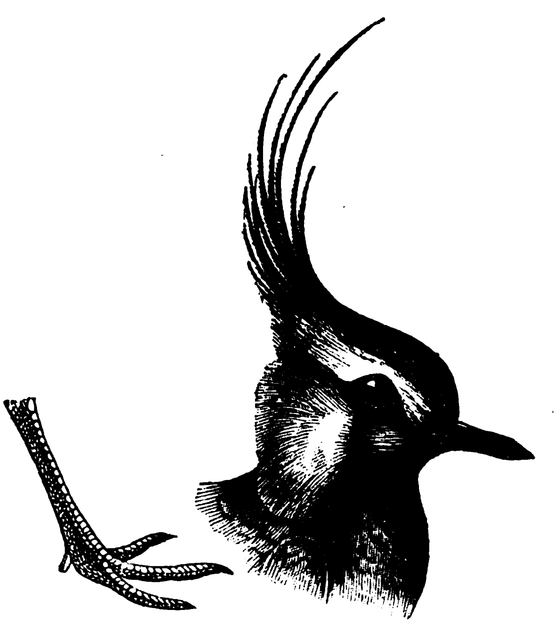
Generic Character.—*Bill* shorter than the head, straight, slightly compressed, the points of both mandibles horny and hard. *Nasal groove* wide, and reaching as far as the horny tip. *Nostrils* basal, linear, pierced in the membrane of the nasal groove. *Legs* slender, with the lower part of the tibiæ naked. *Feet* four-toed; three before and one behind, united at the base by a membrane; hind toe very short, articulated upon the tarsus. *Tarsi* reticulated. *Wings* ample, tuberculated, or spurred. The first three *quill-feathers* notched or suddenly narrowed towards their tips, and shorter than the fourth and fifth, which are the longest. (Gould.)

Example, *Vanellus cristatus*; *Tringa Vanellus*, Linn.

Description.—*Male in winter plumage.*—Occipital feathers very long, loose barbed, and curved upwards. Top of the head, crest, front of the neck and breast glossy black; upper parts deep green with brilliant reflections; sides of the neck, belly, abdomen, and base of the tail pure white; tail feathers terminated by a large black space, with the exception of the external feather; lower coverts ruddy, bill blackish; feet red-brown. Length rather more than twelve inches.

The *female* has the black of the throat and breast less deep.

The *young before the moult* have the occipital crest shorter; some blackish colour below the eyes; the throat



Head and foot of Vanellus.

varied with black and ashy brown; all the feathers of the upper and lower parts terminated with ochreous yellow; feet ashy-olive.

Spring or nuptial plumage.—This is scarcely distinguishable by the greater brilliancy of the reflections on the back and wings, and by the deeper intensity of the black of the throat and breast. The crest however is longer, and the colour of the feet bright reddish.

Accidental Varieties.—Pure white. Yellowish white with faint indications of the deeper colours. One or other part of the body speckled with white feathers. (Temm.)

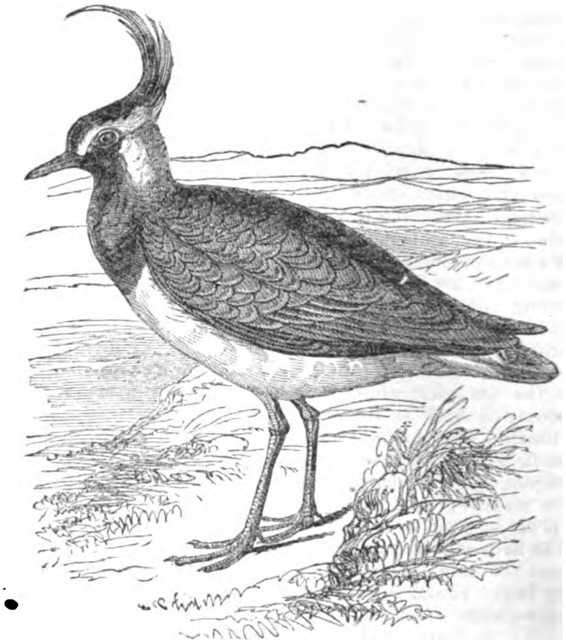
This species is *Le Vanneau* of the French; *Paoncella commune* of the Italians; *Gehaübte Kiebiz* of the Germans; *De Kievit* of the Netherlanders; *Peaseweep*, *Peewit*, *Bastard Plover*, *Lapwing*, and *Wype* of the modern British; *Cornchwigel* of the antient British. It is also the *Wipa*, *Kowipa*, and *Blæcka* of the Swedes; *Vibe* and *Kivit* of the Danes; and, according to Belon, Αἴξ[*] (Aix) of the Greeks (Aristot., *Hist. An.*, viii. 3), *Pavonzino* and *Parruchello* of the Italians; and in some provinces *Dixhuit* and *Pupechieu* of the French.

Habits, Food, Reproduction, Utility to Man, &c.—The habits of this species very much resemble those of the other Plovers, and the arts by which the parents try to lead either dog or man from their eggs or young by counterfeiting the gait of a wounded bird, &c., are as well if not better known as the stratagems of its congeners on the like occasions. This is the bird which furnishes the Plover's eggs of the London market; and those who rob the nest are, it is said, careful not to take all, but they leave one or two, so as to induce the bird to go on laying, which she generally does to make up her number. The full compliment, when the bird is not robbed, is generally four, and they are olive-coloured, spotted and blotched with black. That part of the egg which is usually called the white (the albumen) is transparent when boiled, and has somewhat of a bluish tinge. The nest, if nest it may be called, is the bare earth. It haunts the borders of rivers, lakes, plains, and marshy places, and is generally to be found near the sea-shore in the winter. This part of its habits well agrees with those described as proper to Aristotle's *Aix*, according to the reading given by Belon[†] (*loc. cit.*). This elegant bird seems to have been as much esteemed by the French for the table as by our own countrymen. In the 'Portraits des Oyseaux,' the following quatrain appears under the figure of the bird:—

> 'Voy cy dessus le portraict du Vaneau,
> Et le voyant, pourras ta veue paistre:
> Mais si tu veulx d'un bon morceau repaistre
> Il y a peu de meilleurs oyseaux d'eau.'

In the 'Northumberland Household-Book,' 'Wypes' are charged at one penny each, and they are among the birds admitted to his lordship's own 'mees.'

Geographical Distribution.—Spread over the whole of Europe, and particularly plentiful in Holland. Mr. Gould states that he has seen specimens in collections from India and Africa. It is noted by Messrs. Dixon and Ross as occurring in great numbers near Erzeroom, arriving at the end of March, and departing at the end of November, During the summer it frequents the river (*Karah-soo*, or northern branch of the Euphrates), but on its arrival, and previous to its departure, it is found in moist fields. The native name is *Kiz-Cooshóo* (Maiden's Bird), or *Kahmaum Cooshóo* (Bath-bird). *Vanellus Keptuschka*, and *Charadrii Morinellus* and *minor* were found by those gentlemen at the same locality. (*Zool. Proc.*, 1839.) It appears in the 'List of Birds' seen in Japan, by Dr. von Siebold and M. Bürger; and Temminck states that individuals from that locality differ in nothing from those of Europe.



Vanellus cristatus.

This species is confined to the Old World; but Capt. P. P. King, R.N., has described a second species from the Straits of Magalhaens. It is figured in the 'Illustrations of Ornithology,' under the name of *Squatarola cincta.*

Philomachus, Mœhr; (Hoplopterus, Bonap.)

Example, *Philomachus spinosus*, *Charadrius spinosus*, Linn.; *Pluvialis Senegalensis armata*, Briss.; *Pluvianus spinosus*, Gould.

Description.—Male and Female in perfect plumage.—All the summit of the head and occiput, throat, front of the neck, breast, sides, quills, and three-fourths of the tail black; region below the eyes, lateral base of the bill, sides of the neck, nape, long feathers on the sides, inside of the wings, the whole border of the wing, thighs, abdomen, rump, and first fourth of the origin of the tail pure white; the whole of the mantle, quills nearest the body, as well as all the coverts, grey-brown, more or less deep or umber-colour; two lateral feathers of the tail terminated with white. Length ten to eleven inches.

This is *Le Pluvier à aigrette*, *Le Pluvier huppé de Perse*, and the *Pluvier armé du Senegal* of Buffon; *Spur-winged and Black-breasted Indian Plover* of Latham.

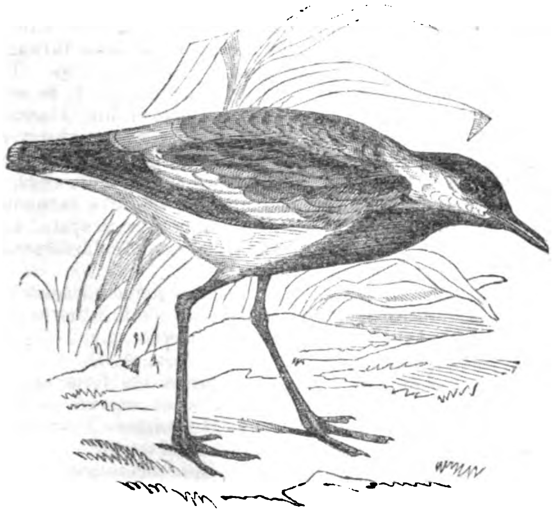
Habits, &c.—Little or nothing is known of the habits of this species, with the exception of what we learn from Dr. Latham, who says that it inhabits Russia, and is frequent near Aleppo, about the river Coie. 'The Spur-winged Plovers,' says he, 'are very numerous and exceedingly noisy, have a hasty and continual movement of the head and neck, drawing them up briskly, and then stretching them quickly forward, almost as if they were making hasty and eager bows.'

Geographical Distribution.—M. Temminck gives Egypt and Senegal as the *habitat*, and says that it shows itself accidentally in Italy, but is said to be more common in the islands of the Archipelago. In Greece, he adds, a great number is found; and Professor Nordmann killed one in Russia.

---

[*] Quære tamen.

[†] But according to other readings it is the αλιαίετος, or Sea-eagle, to which these habits are ascribed.



Philomachus Spinosus.

Himantopus. (Briss.)

Generic Character.—Bill long, slender, cylindrical, flattened at its base and compressed at the point; both mandibles channelled to the extent of half their length from the base. *Nostrils* lateral, linear. *Tarsi* very long and slender. *Toes* three before, the external and middle toe united by a membrane; nails small and flat. *Wings* very long, the first *quill-feather* the longest. (Gould.)

Example, *Himantopus melanopterus; Himantopus rufipes*, Bechst.; *Charadrius Himantopus*, Linn.

Description.—Face, neck, and all the lower parts pure white, assuming a rosy tint on the breast and belly; occiput and nape black or blackish, with white spots; back and wings black, glossed with green; tail ash-colour; bill black; iris crimson; feet vermillion. Length from the point of the bill to the extremity of the tail about fourteen inches, and to the claws about nineteen inches.

The very old male has the nape, and even, sometimes, the occiput, quite white.

The *female* is less than the male; the black of the mantle and wings has no greenish reflexions; and her general tint is browner.

The feet of the *young* are orange; their mantle and wings brown, with whitish edges; feathers of the upper part of the head, occiput, and nape blackish-ash with whitish borders. (*Himantopus Mexicanus*, Briss.) (Temm.)

This is *L'E'chasse* and *E'chasse à manteau noir* of the French; *Cavaliere grande Italiano* and *Cavaliere d'Italia* of the Italians; *Schwarzflügelige Strandreuter* of the Germans; the *Stilt Plover, Long-legged Plover*, and *Longshanks* of the modern British; *Cwttyn hîrgoes* of the antient British.

It is the *Hyperbates Himantopus* of Naumann, and *Himantopus longipes* of Brehm.

Habits, Reproduction, Geographical Distribution, &c.—In tracing the history of this curious form, we must first notice Belon, who, in the 'Portraits d'Oyseaux,' superscribes a by no means bad figure with the following synonyms:—'Grec. Ἱμαντόπους; Italien, Merlo aquaiolo grande; François, Lon pourroit dire, le grand chevalier d'Italie.' Beneath the cut he informs us that the *Himantopus*, like the *Hæmatopus*, has only three toes, but that one is a river and the other a sea bird, and that the former is often seen in all the countries along the river which passes by Castel Durante in the duchy of Urbino. It is there called, he says, *Merlo aquaiolo grande*, in contradistinction to another bird which is simply called *Merlo aquaiolo* (our Water-ouzel, Cinclus?). There is no bird, says Belon, in continuation, which has such long legs with reference to the size of its body; for, having the body of a pigeon, its red legs are a cubit long. After a brief description, he gives the following apotheosis:—'Lon en a mangé à la table de monseigneur le cardinal de Tournon, lors qu'il faisoit sejour en la duché d'Urbin.'

White, in a letter to Pennant, notices the advent of six of these birds to the neighbourhood of his favourite Selborne in his usual charming style.

'In the last week of last month (April, 1779), five of these most rare birds, too uncommon to have obtained an English name, but known to naturalists by the terms of *Himantopus, Loripes*, and *Charadrius Himantopus*, were shot upon the verge of Frinsham-pond, a large lake belonging to the bishop of Winchester, and lying between Wolmer Forest and the town of Farnham in the county of Surrey. The pond-keeper says there were three brace in the flock; but that after he had satisfied his curiosity, he suffered the sixth to remain unmolested. One of these specimens I procured, and found the length of the legs to be so extraordinary, that, at first sight, one might have supposed the shanks had been fastened on to impose on the credulity of the beholder: they were legs in *caricatura;* and had we seen such proportions on a Chinese or Japan screen, we should have made large allowance for the fancy of the draughtsman. These birds are of the *plover* family, and might with propriety be called *stilt plovers.* Brisson, under that idea, gives them the appropriate name of l'échasse. My specimen, when drawn and stuffed with pepper, weighed only four ounces and a quarter, though the naked part of the thigh measured three inches and a half. Hence we may safely assert that these birds exhibit, weight for inches, incomparably the greatest length of legs of any known bird. The *flamingo*, for instance, is one of the most long-legged birds, and yet it bears no manner of proportion to the *himantopus;* for a cock *flamingo* weighs at an average about four pounds avoirdupois; and his legs and thighs measure usually about twenty inches. But four pounds are fifteen times and a fraction more than four ounces and one-quarter; and if four ounces and a quarter have eight inches of legs, four pounds must have one hundred and twenty inches and a fraction of legs, *viz.* somewhat more than ten feet, such a monstrous proportion as the world never saw! If you should try the experiment in still larger birds, the disparity would still increase. It must be matter of great curiosity to see the *Stilt Plover* move; to observe how it can wield such a length of lever with such feeble muscles as the thighs seem to be furnished with. At best one should expect it to be but a bad walker; but what adds to the wonder is, that it has no back toe. Now without that steady prop to support its steps, it must be liable in speculation to perpetual vacillations, and seldom able to preserve the true centre of gravity. The old name of *Himantopus* is taken from Pliny; and, by an awkward metaphor, implies that the legs are as slender and pliant as if cut out of a thong of leather. Neither Willughby nor Ray, in all their curious researches, either at home or abroad, ever saw this bird. Mr. Pennant never met with it in all Great Britain, but observed it often in the cabinets of the curious at Paris. Hasselquist says that it migrates to Egypt in the autumn; and a most accurate observer of nature has assured me that he has found it on the banks of the streams in Andalusia. Our writers record it to have been found only twice in Great Britain From all these relations it plainly appears that these long-legged plovers are birds of South Europe, and rarely visit our island; and when they do, are wanderers and stragglers, and impelled to make so distant and northern an excursion from motives and accidents for which we are not able to account. One thing may fairly be deduced, that these birds come over to us from the Continent, since nobody can suppose that a species not noticed once in an age, and of such a remarkable make, can constantly breed unobserved in this kingdom.'

The passage in Pliny from which the name *Himantopus* is taken must be, we presume, that in the eighth chapter of the fifth book on the *Æthiopes:* 'Himantopodes loripedes quidam, quibus serpendo ingredi natura est.'

Pennant says, 'These birds are extremely rare in these islands. Sir Robert Sibbald records a brace that were shot in Scotland; another was shot a few years ago at Stanton-Harcourt Common near Oxford; and we have seen them often in the cabinets of the curious at Paris, taken on the French coasts.'

Mr. Selby observes that the members of this genus, remarkable for the disproportionate length and the slenderness of their legs, are not numerous, but possess a very wide geographical range, some one of the species being found in every quarter of the globe. By the earlier authors, when only one species was recognised, it was, he remarks, placed among the typical Plovers. Its affinity to the Plovers is shown, he adds, in the form of its feet, and the passage to the genus *Charadrius* is effected through the interposition of some of the longer-limbed species, and by the members of the genus *Pluvianus*. It also connects, he thinks, the Plovers with certain groups of the *Scolopacidæ*, as it shows an evident affinity, both in form and manners, to the Avosets (*Recurvirostra*), amongst which Wilson was led to place the North American species, from the great similarity observed by him in their respective habits. Mr. Selby states that the species before us inhabits the shores of the ocean, as well as of interior saline and fresh-water lakes, feeding upon worms, insects, larvæ, &c., which are obtained in the muddy shallows of the waters they frequent. Mr. Selby further remarks that their moult is presumed by Temminck to be double, for the fact does not appear to be established by actual observation. (*Illustrations of British Ornithology*.)

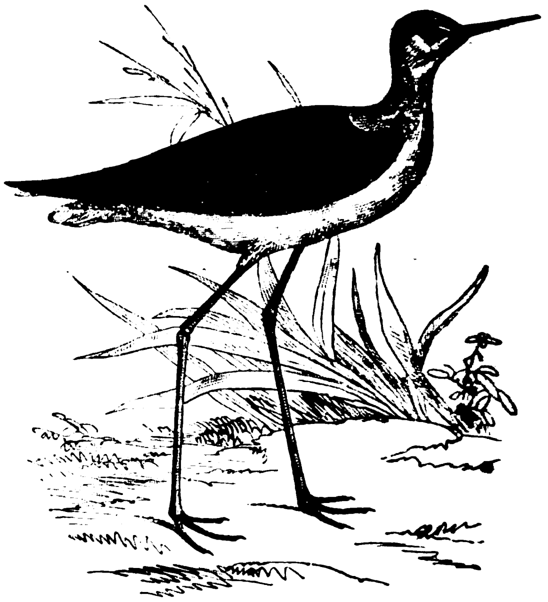
Mr. Gould (*Birds of Europe*) states that the genus *Himantopus*, although widely distributed, contains, he believes, only two well authenticated species, namely, *Him. melanogaster* and the North American species. 'This bird,' says Mr. Gould, in continuation, 'so singular in its appearance from the extraordinary length and slenderness of its legs, has been often killed in England; but it must be classed among those birds whose visits are accidental and uncertain. It is equally scarce in Holland and the northern portion of Europe; in fact, though apparently abundant nowhere, it exhibits so wide a range, that its deficiency in point of number in any given locality is counterbalanced by its almost universal distribution. We have been presented with skins, which we consider to belong to this same species, from Africa, India, the islands of the Indian Archipelago, and, if we mistake not, from North and South America. The Long-legged Plover, as its conformation would lead us to conclude, is a bird whose most congenial habitat is morasses and the low flat shores of lakes, rivers, and seas. Hence in the eastern portions of Europe, where it is said to arrive from Asia in small flocks, it takes up its abode along the lakes and among the vast morasses of Hungary and Russia, where, according to M. Temminck, it rears its progeny, and where it fearlessly wades in search of its food, without much chance of being carried out of its depth; but should such an occurrence happen, or the waves drift it out from the shore, it possesses, like many of the true Wading Birds, the power of swimming with the greatest ease and lightness: in fact, in whatever point of view we consider the Long-legged Plover, we find it adapted in the best possible manner for its habits and modes of life. Few birds exceed it in the powers of flight; its wings far exceed the tail, and it passes through the air with astonishing rapidity. When on firm ground, it appears as if tottering on long and awkward stilts, but firm ground is not its congenial habitat. The egg, as figured by Dr. Thienemann, measures one inch nine lines in length by one inch three lines in breadth, of a pale bluish-green, spotted and specked with dark brown.'

The species is recorded in the catalogue of birds collected on the Ganges between Calcutta and Benares, and in the Vindhyian hills between the latter place and Gurrah Mundela on the Nerbuddah, by Major James Franklin, F.R.S. (*Zool. Proc.*, 1830-31.) Lieutenant-Colonel Sykes notes it in his 'Dukhun' list with the following observations:—'There are slight discrepancies in the plumage between the birds of Java, India, and Europe; and in case of these being permanent and not the result of nonage, specific differences might be established. *Irides* narrow, lake or crimson colour. Length, inclusive of tail, 16 inches; tail 3¼ inches; to the end of the toes, 22½ inches. Gregarious. Vegetable matters, larvæ of water insects, and minute univalve shells found in the stomach. These birds are strangely polluted with visceral worms of the tape and capillary kinds.' (*Zool. Proc.*, 1832.) Mr. Thompson, in his 'Catalogue of Irish Birds,' records that, in the winter of 1823, a bird of this species was seen by Mr. Ball in the neighbourhood of Youghal. (*Zool. Proc.*, 1834.) Messrs. Dickson and Ross saw it near Erzeroom at the end of July. It was not very common, and haunted the borders of the river. There was a naked rim round the eye-lid, of a bright vermillion colour. (*Zool. Proc.*, 1839.) It has also been noticed at Trebizond by Mr. Keith Abbott. (*Zool. Proc.*) Colonel Sykes, in his observations on Captain Spiller's collection of birds formed at the Cape of Good Hope, notices *Himantopus melanopterus* as universal. M. Temminck states that individuals killed in Egypt do not differ from the European specimens; neither do those brought from Brazil by the Prince de Wied. The only difference is, that the Egyptian and Brazilian birds are larger. American specimens, also received by M. Temminck, differed in nothing from those in Europe, and he adds that it is asserted that the species is the same throughout India, but he has had no means of verifying this. The Long-legged Plover figured by Wilson (pl. 58, f. 2) he considers distinct and new. In the last part of his 'Manual' (1840) he states that the Japanese specimens exhibit no difference, and that the bird makes its nest upon a little eminence constructed in the marshes, laying four eggs, of the size and form of those of the Avoset, of a tarnished green colour, marked with numerous ashy spots, and dotted with moderate-sized and very small reddish-brown spots.

Mr. Gould considers that the species found in Australia and the islands of Java and Sumatra, though hitherto confounded with *Him. melanogaster*, is different, and he names it *Himantopus leucocephalus*. (*Zool. Proc.*, 1837.)

The Prince of Musignano, who places the form among the *Recurvirostridæ*, makes *Himantopus nigricollis* (*Recurvirostra Himantopus*, Wils.) and *Himantopus Mexicanus*, Briss., from the northern and central and southern parts of America respectively, distinct from *Him. melanogaster*.

Mr. Swainson informs us that, in his opinion, the species from Western Africa, although confounded by most naturalists with *Him. melanogaster*, is certainly different, being characterised by greater size, greater length of wing, and a peculiar grey colour on the head and neck, which is not found in either European or American species.



Himantopus melanogaster.

The Pratincole (*Glareola*), the Sea Pie (*Hæmatopus*), and the Turnstone (*Strepsilas*), will be treated of under their respective titles.

PLOWDEN, EDMUND, serjeant-at-law, was an eminent lawyer, who flourished in the reign of Mary and the early part of that of Elizabeth. He was the representative of an antient family, Plowden of Plowden in Shropshire. He was born about the year 1517, and after having in early life studied medicine and surgery, first at Cambridge, and afterwards at Oxford, is said by Anthony Wood to have changed the course of his studies to the common law when he was thirty-five years of age. But this statement is totally at variance with Plowden's own account of himself, for he says, in the preface to his 'Commentaries,' that he entered on the study of the law in the twentieth year of his age, and in the thirtieth of the reign of King Henry VIII. (Preface to his *Comm.*, which is well worth reading.) He was twice a reader of the Middle Temple, and about the close of the reign of Mary was called to the degree of serjeant-at-law; but he was omitted in the call of serjeants in the 2 Elizabeth, possibly because, as is suggested in a note to Wood's account of him, he was an 'unalterable papist.' He died in 1584, and was buried in the Temple Church, where a monument to his memory still remains. Camden says of him (*Annal. Reg. Eliz.*, an. 1584), 'ut in juris Anglici scientiâ, de quâ scriptis benè meruit, facilè primus, ita vitæ integritate inter homines suæ professionis, nulli secundus.' His devotion to legal studies was so great, that there is a professional tradition that 'in three years, he went not once out of the Temple.' (Wood's *Athenæ*, vol. i., p. 504, note.)

The high reputation of Plowden in the legal profession rests entirely upon the character of his Reports or Commentaries. This work consists of a collection of the Reports of important cases, executed with great fidelity and care, and extending from the reign of Edward VI. to the middle of the reign of Elizabeth. The first complete edition of Plowden's 'Commentaries' is in black-letter and Norman French, fol., 1684; the second edition, likewise in folio, is translated into English, fol., 1761. There is also an octavo reprint of the 'Commentaries,' London, 2 vols., 1816. (Wood's *Athenæ Oxonienses;* Burke's *History of the Commoners of England*, vol. iii., p. 251.)

PLUM. The *Prunus domestica* is generally considered as the species which has given rise to the numerous varieties of this fruit; but both *Prunus insititia* and *P. spinosa* have most probably contributed. These species are indigenous to a great portion of the northern hemisphere, Britain included. Their range may be stated to extend from Norway to Barbary, and from Portugal to Cashmere, and even Nepaul. Damascus was formerly celebrated for this fruit: branches of the plum are represented on Damascus medals; and many of the varieties now in cultivation still retain the name of this place, or it is employed as a distinguishing prefix to a number of subvarieties; thus the French enumerate upwards of twenty varieties of *Damas*. In this country the name of *Damascene* was given to those varieties which may be supposed to have been brought from Damascus, or to others similar; but the corruption of this to *Damson* has been long established. Whatever region may be the origin of them, it is certainly to France that we are indebted more immediately for the greater part of the varieties now actually cultivated.

In the 'Catalogue of Fruits,' published by the Horticultural Society, 274 varieties are named. It is not however to be presumed that all these will prove distinct, but upwards of 200 at least may be reckoned as such. A selection of the best of these may prove useful; and as some means of ascertaining whether they are correctly named by the nurserymen who sell them, the following simple mode of arrangement will be found useful:—

Class I.

* FRUIT PURPLE.
  a. *Round.*
    Shoots smooth. § 1.
    Shoots downy. § 2.
  b. *Oblong.*
    Shoots smooth. § 3.
    Shoots downy. § 4.

Class II.

** FRUIT PALE.
  a. *Round.*
    Shoots smooth. § 5.
    Shoots downy. § 6.
  b. *Oblong.*
    Shoots smooth. § 7
    Shoots downy. § 8.

Varieties of plums most deserving of cultivation, arranged according to the preceding classification, are the following:—

§ 1.
Reine Claude Violette, or purple gage.
Nectarine plum
Kirke's.
Virgin.
Queen-mother.

§ 2.
Royale Hâtive.
Orleans.
Early Orleans.
Coe's Fine Late Red.
Wine-sour.

§ 3.
Blue Imperatrice.
Ickworth Imperatrice.
Cooper's Large Red.

§ 4.
Blue Perdrigon.
Shropshire Damson.

§ 5.
Green Gage.
Knight's Large Green Drying.
Lucombe's Nonsuch.

§ 6.
Drap d'Or.
Mirabelle.
Washington.

§ 7.
Coe's Golden Drop.
St. Catherine.
White Magnum Bonum.

§ 8.
Gumaraen.
White Perdrigon.

The cultivation of the plum is not difficult. The tree is hardier than the cherry-tree, at least than that producing the Bigarreau and Heart-cherries; but the blossoms are equally tender. The winter at Riga does not kill the plum-tree, but the cherry-trees just mentioned and many varieties of the pear and apple trees are killed there. The severe frost of January, 1838, contrary to expectation, did not injure the fruiting of the plums in the following summer. The trees succeed in any free soil, not too dry, but by no means stiff or clayey. Their roots extend horizontally, and are apt to throw up suckers, which must be destroyed on their first appearance, otherwise they rob the tree, and form protuberances on the roots. Too much manure will actually kill the trees; and at all times a medium state of vigour should be aimed at. Excessive luxuriance is the forerunner of gummy exudations; and, on the other hand, if the tree be stunted and the vessels contracted by drought or other causes, whereby the sap is obstructed, gum is in that case also induced. Pruning should be applied to the plum in the same manner as to the peach; and in the management of standards care should be taken to destroy useless limbs on their first appearance, instead of waiting till the shoots to be removed become large branches. The varieties are propagated both by budding and grafting; and for the latter, as the buds push early, the cuttings should be taken off not later than February.

PLUMATELLA, a fresh-water genus of POLYPIARIA DUBIA.

PLUMBA'GIN, a vegetable principle existing in the root of the *Plumbago Europæa*. This substance is of a lemon-yellow colour, and crystallizes in prisms or fine needles of considerable brilliancy. It has a sweetish taste, but leaves an acrid hot impression in the mouth. It melts in a gentle heat, and assumes a crystalline appearance on cooling. When more strongly heated, a small portion sublimes, and the greater part is decomposed, no ammonia being evolved.

Though very slightly soluble in water, the solution has a yellow colour; when dissolved in boiling water, yellow crystals are deposited on its cooling. It is more soluble in alcohol and æther and dilute acids than in water; in the alkalis it is also very soluble, and the solutions are red. The yellow colour is restored by the addition of an acid. When added to a solution of di-acetate of lead, a crimson-red precipitate is gradually formed. Plumbagin does not appear to have been analyzed.

PLUMBAGINA'CEÆ are a small natural order of monopetalous exogens, with a compound superior one-celled one-seeded ovary, the ovule in which is supported upon a long curved funiculus or cord. They are usually plants with a showy flower, herbaceous or under shrubby, with several styles or stigmata, and a powerful acrid or astringent quality. The principal genus of the order is the *Statice*, whose many species, under the name of *Sea Lavenders*, inhabit the salt-marshes or cliffs of all the temperate parts o Europe. The prevailing colour of the flowers is blue; the instances of yellow, or any other colour, being more rare. Garden Thrift, *Armeria vulgaris*, a plant frequently used for an ornamental bordering in flower-gardens, is said to possess powerful diuretic qualities in its petals.

Plumbago capensis.

1, a flower deprived of corolla and stamens; 2, the ovary, and stamens surrounding it; 3, a vertical section of the ovary, showing the peculiar position of the ovule.

PLUMBA'GO—*Graphite, Black Lead.* This substance occurs crystallized and massive. Primary form a rhomboid. Occurs in imbedded hexagonal prisms. Cleavage parallel to the terminal planes of the prism, very distinct, and the laminæ flexible. Fracture granular and uneven. Hardness 1·0 to 2·0. Colour steel or blackish-grey. Streak black, shining. Lustre metallic and glistening. Unctuous to the touch. Opaque. Specific gravity 2·08 to 2·45.

Found in Greenland and in the neighbourhood of Philadelphia in the United States.

Massive varieties occur amorphous, in reniform masses, and irregular nodules. Structure foliated, granular, compact.

Found in various parts of the world. That of Borrowdale in Cumberland is of the best quality for what are called black-lead pencils; while the commoner sorts are used for making melting-pots, for diminishing the friction of machinery, and for protecting iron from rusting. That which is imported from the East Indies is remarkably soft. Plumbago conducts electricity, is infusible, and very difficult of combustion.

Professor Vanuxem has analyzed several varieties of plumbago. No. 1 was a pure specimen from Borrowdale, and No. 2 from Bustletown, Pennsylvania.

	No. 1.	No. 2.
Carbon .	88·37	94·4
Silica .	5·10	2·6
Alumina .	1·00	—
Water .	1·23	0·6
Oxides of iron and manganese .	3·6	1·4
	99·30	99·0

It was at one time supposed that plumbago was a carburet of iron, but, in the opinion of Berzelius, the experiments of Karsten have proved that it is a peculiar form of carbon, and that the substances which it contains are in a state of mixture merely and not of chemical combination.

According to Dr. Thomson, plumbago is found usually in primary or transition rocks. At Borrowdale it occurs in nests in a greenstone rock, which constitutes a bed in clay-slate. In Inverness-shire it occurs in gneiss; at Arendal in Norway, in quartz rock; and in the United States, in felspar and mica-slate, but always in primary rocks.

PLUMBLINE. When a heavy body suspended by a flexible string is at rest, the line passing through the point of suspension and the centre of gravity of the weight is in the direction in which gravity acts. The *horizon* is a plane perpendicular to this line, and the *zenith* is that point of the heavens marked out by the continuation of the line upwards. If the string be *perfectly* flexible, it will coincide with the theoretical line above described.

The application of the plumbline to the arts does not require any explanation here. We shall briefly mention the manner of applying the plumbline to astronomical instruments, and it is necessary to mention it, as in most cases it has been superseded by the spirit level, or observation by reflexion, and so is not described in the account of the instruments.

In the earlier astronomical instruments, where the telescope or line of sight was moveable and the limb of the instrument fixed, two fine dots were made on some part of the instrument, as distant from each other as possible, and parallel to that radius, which was required to be vertical. A fine line was hung in front of the dots, and made to bisect the upper dot by a slow screw motion carrying the wire. The lower dot was then brought under the plumbline by the adjustments of the instrument, and when both were at the same time accurately bisected, the rectification of the instrument in this respect was complete. The weight below was *completely* immersed in water to diminish its oscillations, and the exact bisection of the dots by the wire was inspected by microscopes. The plumbline was brought as close to the dots as was consistent with perfect freedom, and at the same distance from each as nearly as could be judged. It was also protected by a covering from the influence of the wind.

In instruments of this construction, the bisection of the dots by the plumbline should be noted at the same time as the object is observed by the telescope. As the plumbline in its ordinary position was sometimes in the way of the telescope, two other dots were frequently inserted, which, being verified by the principal dots, could be used for the same purpose of verification; and it is evident, that while the framework of the instrument continues unchanged, the verticality of the line passing over the supplementary dots will ensure the verticality of the line passing over the primary dots, since the two lines are parallel. A simple plumbline, as above described, was universally used up to the latter end of the last century for rectifying instruments employed in measuring altitudes, or zenith distances, in which the telescope and its vernier moved on a fixed limb. When the telescope and limb were united, the plumbline was made to pass over the centre of the divisions, and marked out the division which corresponded to the altitude, the fractional part being measured by the screw which moved the whole instrument until the next division was bisected. Instruments of the latter kind were not, we conceive, much known in this country, but we believe they were used in France.

About 1785 (for we can find no exact date) Ramsden introduced a great improvement in the application of the plumbline. The *images* of the dots on the instrument were formed on the plumbline by interposing lenses, and the bisection of the image by the plumbline was viewed through microscopes. The plumbline was thus kept out of the way of the observer, and the optical parallax destroyed. This apparatus was, we believe, called Ramsden's *Ghost.* But the ghost is liable to this objection when applied to circles in which the telescope and limb are fixed and revolve together, and the angles read off by microscopes, viz. that the dots are never visible upon the plumbline at the time of observation, but only before or after, at the moments of adjustment, so that a derangement may take place unnoticed. For circles which do not turn in azimuth, this objection seems incurable (not that it is of much importance, as, from the superior stability of their framing and mounting, transit circles can scarcely be liable to any sudden error), but the present mode of observing by reflexion does away with the use of the plumbline altogether in instruments of this construction. In circles revolving freely in azimuth, the following modification of Ramsden's plumbline, which was introduced by Troughton, is much to be preferred to it.

On considering the mode in which the zenith distance of an object is measured by a circle revolving freely in azimuth, it will be seen that, by combining two observations in reversed positions of the circle, we have the true distance measured from that point in which the axis of rotation when continued cuts the heavens. If the axis is truly vertical, this point is the zenith, and the purpose of Troughton's plumbline is to set the axis truly vertical. An upright tube is attached to the upper part of the instrument, which revolves freely in azimuth, the plumbline hangs in the tube over a notch, the weight below being wholly immersed in water. Near the bottom of the tube, two smaller tubes cross it at right angles to each other and to the principal tube. In each of these smaller tubes is the following apparatus:—at one end a mother-of-pearl disc with a dot, then a lens which forms an image of the dot on the plumbline, and at the other end a microscope to note the bisection. The dot is a little excentric, and the tube has sufficient play to admit of the adjustment being effected very nicely. Now when both the dots have been properly bisected by the plumbline, turn the instrument half round, and look at them again. It is clear that if the axis of rotation were vertical, it would be parallel to the plumbline in both positions, and the dots would be still bisected. If not, by touching the foot-screws, the dots can be brought half way to bisection, and then fully bisected by their own adjustments. When this is done, the axis is truly vertical. The operation must of course be repeated and continued until the dots are bisected by the plumbline in every position of the instrument, when the axis is truly vertical. [CIRCLE.] But though Troughton's plumbline is exceedingly beautiful and accurate, we greatly doubt whether it is so effective as a spirit-level. It is much more troublesome to adjust, there are no means of *measuring* its deflexions (these might be given), it is a longer time in coming to rest, is more liable to cause and to receive injury, and unless the instrument be reversed *after every observation*, it is as likely to vary from temperature as the level. We should therefore strongly dissuade any one from applying the plumbline to any instrument except the zenith sector, as it may in all other cases be either advantageously replaced by a level or superseded by observations from mercury. [ZENITH SECTOR.]

(Pearson's *Astronomy*, vol. ii., p. 285, and most of the circles described in that work; Pond, 'On the Westbury Circle,' *Phil. Trans.*, 1806, p. 420; 'Circle,' Brewster's *Cyclopædia*.)

PLUTARCHUS was a native of Chæronea in Bœotia. The time of his birth is uncertain, and can only be approximately ascertained from the circumstance stated by himself, that he studied philosophy under Ammonius at Delphi, at the time when Nero was making his progress through Greece, which was in the twelfth year of the emperor's reign, or A.D. 66 (*Περὶ τοῦ Εἰ ἐν Δελφοῖς*, c. 1). The family of Plutarch was one of some consideration in Chæronea, and had held the chief offices in that city. Plutarch mentions his great-grandfather Nicarchus, who told him what the citizens of Chæronea suffered from Antony's soldiers; and he speaks of his grandfather Lamprias as a good-humoured man and an agreeable companion. He has not mentioned his father's name in his extant works. He had two brothers, Timon and Lamprias, to whom he was much attached. When a young man, he was sent with another person on a mission to the proconsul of the province. His companion was from some cause left behind, and Plutarch executed the business himself (*Πολιτικὰ παραγγέλματα*, c. 20).

It has sometimes been asserted that Plutarch visited Egypt, but there is no authority for this assertion, and such a conclusion cannot be drawn, as it sometimes has been, from such slender premises as are furnished by the fact of his writing an essay on Isis and Osiris. Plutarch visited Italy and Rome, perhaps more than once, and he spent some time there, as appears from his own writings (*Life of Demosthenes*, c. 2); but he did not learn the Latin language in Italy, according to his own account; and the reason that he gives for not then learning it is a curious one: 'he had so many public commissions, and so many people came to him to receive his instruction in philosophy.' 'It was therefore,' he adds, 'not till a late period in life that I began to read the Latin writers.' It appears clearly enough from his own writings that he never thoroughly mastered the Latin language, and was very imperfectly acquainted with the antient institutions which formed the groundwork of the Roman polity and the Roman character. It has been conjectured with reasonable probability that his moral writings contain much of the matter which he delivered in his public lectures in Italy. He wrote his Life of Demosthenes at Chæronea, after he had visited Rome, but whether he wrote any of his Lives during his long residence in Rome is uncertain. It may be that they are the work of his old age, and that all of them were written or finished in his native city.

It is generally said that Plutarch was the preceptor of Trajan, and was raised by him to the consular rank; but these facts rest on the assertion of Suidas (*Πλούταρχος*), and on an extant letter addressed to Trajan, which is attributed to Plutarch. It is true that in the dedication of the Apophthegms (*Ἀποφϑέγματα βασιλέων καὶ στρατηγῶν*) to Trajan, Plutarch says nothing about either of these circumstances; but then it is argued that the Apophthegms are not by Plutarch, for he says in the dedication, that he had already written the lives of illustrious Greeks and Romans; and if we admit that he wrote the Lives at Chæronea when he was an old man, and that he did not return there till after Trajan's death, it follows that he did not write the Apophthegms, or at least the dedication prefixed to them. But the letter to Trajan, which is attributed to Plutarch, bears conclusive internal testimony of being a fabrication. Besides this, it only exists in Latin, and in the 'Policraticus' of John of Salisbury; the Greek original has never been produced, and it is not known where John found this letter.

Plutarch seems to have enjoyed considerable distinction at Rome, and his lectures, which of course were delivered in the Greek language, were attended by most of those who affected philosophy. His lectures were given as early as the reign of Domitian, or perhaps even in the reigns of Vespasian and Titus, as we learn from a curious anecdote of his own (*περὶ πολυπραγμοσύνης*, c. 15); and he enjoyed the friendship of several distinguished Romans, as Arulenus Rusticus, whom Domitian put to death (Tacit., *Agr.*, 2), and Sossius Senecio, a man of consular rank, whom he addresses in the introduction to the Life of Theseus, and elsewhere in his writings.

Among his contemporaries at Rome were Persius, Lucan, the younger Pliny, Martial, Quintilian, and others, but none of them have made any mention of Plutarch, though he must have been known to them. Sossius Senecio, one of his intimate friends, was also a friend of the younger Pliny, who addresses him in his Letters. He retired to Chæronea in the decline of his life, where he appears to have lived in comfort. He faithfully discharged various magisterial offices in his native town, and he had also the honour and emoluments of a priesthood.

Plutarch had a wife,. Timoxena, to whom he was tenderly attached, and four sons, and a daughter, Timoxena. Two of his sons died before him, and he lost his daughter while an infant. It was on the occasion of this child's death that he wrote that affectionate letter of consolation, full of good sense, in which he has perpetuated the virtues and fortitude of a most exemplary wife and mother (*Παραμυϑητικὸς πρὸς τὴν ἰδίαν γυναῖκα*).

The time and circumstances of Plutarch's death are unknown, and indeed the events of his life, as will appear from this sketch, are imperfectly ascertained; but the character of the man is as familiar to us from his own writings as if we possessed the most elaborate biography of him.

The great work of Plutarch is his 'Parallel Lives' (*Βίοι Παράλληλοι*), which contains the biography of forty-six distinguished Greeks and Romans, besides the Lives of Artaxerxes Mnemon, Aratus, Galba, Otho, and Homer, which last is probably not by him. The forty-six Lives are arranged in pairs or sets, each of which contains a Greek and a Roman, and the two lives in each pair are followed by a comparison of the characters of the two persons. These Lives are—Theseus and Romulus, Lycurgus and Numa, Solon and Valerius Publicola, Themistocles and Camillus, Pericles and Fabius Maximus, Alcibiades and Coriolanus, Timoleon and Æmilius Paulus, Pelopidas and Marcellus, Aristides and Cato Major, Philopœmen and Flamininus, Pyrrhus and Marius, Lysander and Sulla, Cimon and Lucullus, Nicias and Crassus, Eumenes and Sertorius, Agesilaus and Pompeius, Alexander the Great and Julius Cæsar, Phocion and Cato Minor, Agis and Cleomenes and the two Gracchi, Demosthenes and Cicero, Demetrius Poliorcetes and M. Antonius, Dion and M. Brutus. The biographies of

Epaminondas, Scipio, Augustus, Tiberius, Caligula, Claudius, Nero, Vitellius, Hesiod, Pindar, Crates the Cynic, Daiphantus, Aristomenes, and the poet Aratus, are lost.

Plutarch's son Lamprias made a list of his father's works, *Πλουτάρχου βιβλίων πίναξ*, which is partly preserved, and printed in the 'Bibliotheca Græca' of Fabricius.

In the department of biography, Plutarch is the only writer of antiquity who has established a lasting reputation. The plan of his biographies is briefly explained by himself in the introduction to the Life of Alexander the Great, where he makes an apology for the brevity with which he is compelled to treat of the numerous events in the lives of Alexander and Cæsar. 'For,' he says, 'I do not write Histories, but Lives; nor do the most conspicuous acts of necessity exhibit a man's virtue or his vice, but oftentimes some slight circumstance, a word or a jest, shows a man's character better than battles with the slaughter of tens of thousands, and the greatest arrays of armies and sieges of cities. Now, as painters produce a likeness by a representation of the countenance and the expression of the eyes, without troubling themselves about the other parts of the body, so I must be allowed to look rather into the signs of a man's character, and thus give a portrait of his life, leaving others to describe great events and battles.' The object then of Plutarch, in his Biographies, was a moral end, and the exhibition of the principal events of a man's life was subordinate to this his main design; and though he may not always have adhered to the principle which he laid down, it cannot be denied that his view of what biography should be, is much more exact than that of most persons who have attempted this style of composition. The life of a statesman or of a general, when written with the view of giving a complete history of all the public events in which he was engaged, is not biography, but history. This extract from Plutarch will also in some measure be an apology for the want of historical order observable in many of the Lives. Though altogether deficient in that critical sagacity which discerns truth from falsehood, and disentangles the intricacies of confused and conflicting statements, Plutarch has preserved in his Lives a vast number of facts which would otherwise have been unknown to us. He was a great reader, and must have had access to large libraries. It is said that he quotes two hundred and fifty writers, a great part of whose works are now entirely lost.

There are two purposes for which the Lives of Plutarch may be read. We may read them for the pleasure of the perusal, which arises from a conviction of the integrity of the writer, and his graphic representations, his benevolent disposition, and the moral end which he always keeps before him. We may also read them for the purpose of a critical investigation into the facts which he has recorded, and for the purpose of supplying from him the defects of other antient authorities. With this latter object we must institute a searching inquiry into the authorities for the several Lives, which vary greatly in value; and above all we must be careful in reading his Lives of the Romans not to be misled by any notions that he had formed of the institutions of a people with whose language he was imperfectly acquainted, and to whose antient history he was nearly a stranger. On the sources of Plutarch's Lives the reader may consult an essay by A. H. L. Heeren, *De Fontibus et Auctoritate Vitarum Parallelarum Plutarchi Commentationes IV.*, Goettingæ, 1820, 8vo.

Besides the Lives, a considerable number of Plutarch's essays may be styled historical. They may all be read with pleasure and some of them with instruction, not so much for their historical value as for the detached curious facts that are scattered so profusely through Plutarch's writings, and for the picture which they exhibit of the author's own mind. In one of these essays, entitled 'On the Malignity of Herodotus' (*περὶ τῆς Ἡροδότου κακοηϑείας*), he has, unfortunately for his own reputation, attacked the veracity and integrity of the father of history, and with the same success that subsequent writers, more ignorant and less honest, have made their puny attacks on a work the merit of which the closest criticism may enhance but can never depreciate. (*Journal of Education*, vol. vii., p. 128.) The 'Lives of the Ten Orators,' which are attributed to Plutarch, are of little value, and may not be his; still they bear internal evidence, at least negatively, of not being of a later age than that of Plutarch.

The Lives of Plutarch first appeared in a Latin version by several hands, at Rome, in 2 vols. fol., about 1470. This Latin version formed the basis of various Spanish and Italian translations. The first Greek edition was printed by Philip Giunta, Florence, 1517, fol. Among more recent editions are those of Bryan, London, 1729, 5 vols. 4to., in Greek and Latin, which was completed by Moses du Soul, after Bryan's death; that of Coray, Paris, 1809-1815, 6 vols. 8vo.; and that by Schaefer, Leipzig, 1826, 6 vols. 8vo. The translations are very numerous. The best German translation is said to be by Kaltwasser, Magdeburg, 1799-1806, 10 vols. 8vo. Another German translation appeared at Vienna, in 1812. The best Italian translation is by Pompei. The French translation of Amyot, which appeared in 1559, has considerable merit, and has been often reprinted. The English translation of Sir Thomas North, London, 1612, which is avowedly made from that of Amyot, is often very happy in point of expression, and is deservedly much esteemed. The Lives were also translated into French by Dacier, Paris, 8 vols. 4to., 1721. The translation sometimes called Dryden's, the first volume of which was published in 1683, was executed by a great number of persons. According to a note by Malone (Dryden's *Prose Works*, ii., p. 331), there were forty-one of them. Dryden himself translated nothing, but he wrote the dedication to the duke of Ormond, and the Life of Plutarch, which is prefixed to the translation. The last English translation is by John and William Langhorne, an insipid and tasteless version, which has the merit of being tolerably correct in rendering the meaning of the original. It has a few notes of little value, and is prefaced by a very uncritical and ill-written Life of Plutarch. There is an edition of this version by archdeacon Wrangham, with corrections and additions, which add little to the value of the Langhornes' labours.

The other writings of Plutarch, which consist of about sixty essays, are generally comprehended under the title of his 'Moralia, or Ethical Works,' many of them being entirely of an ethical character. The minor historical pieces already referred to, of which that on the malignity of Herodotus is one, are usually comprised in the collection entitled 'Moralia.' Plutarch was fond of the writings of Plato; he was strongly opposed to the Epicureans: if he belonged to any philosophical sect, it was that of the Academics. But there is nothing like a system of philosophy in his writings, and he is not characterised by depth of thought or originality. He formed for himself a system, if we may so name that which had little of the connected character of a system, out of the writings of various philosophers. But a moral end is always apparent in his 'Moralia' as well as in his Biographies. A kind humane disposition and a love of everything that is ennobling and excellent, pervade his writings, and give the reader the same kind of pleasure that he has in the company of an esteemed friend, whose singleness of heart appears in everything that he says or does. Plutarch rightly appreciated the importance of education, and he gives many good precepts for the bringing up of children. His philosophy was practical, and in many of its applications, as for instance his 'Letter of Consolation to Apollonius,' and his 'Marriage Precepts,' he is as felicitous in expression as he is sound in his precepts. Notwithstanding all the deductions that the most fastidious critic may make from Plutarch's moral writings, it cannot be denied that there is something in them which always pleases, and the more the better we become acquainted with them; and this is no small merit in a writer.

Plutarch's style bears no resemblance to the simplicity of the Attic writers. It has not the air of being much elaborated, and apparently his sentences flowed easily from him. He is nearly always animated and pleasing, and the epithet pictorial may be justly applied to him. Sometimes his sentences are long and ill constructed, and the order of the words appears not the best that could be chosen to express his meaning: certainly it is not the order in which the best Greek writers of an earlier age would have arranged their thoughts. Sometimes he is obscure, both from this cause and the kind of illustration in which he abounds. He occasionally uses and perhaps affects poetic words, but they are such as give energy to his thoughts and expression to his language. Altogether he is read with pleasure in the original by those who are familiar with him, but he is somewhat harsh and crabbed to a stranger. It is his merit, in the age in which he lived, treating of such subjects as biography and morals, not to have fallen into a merely rhetorical style, to have balanced antitheses, and to have contented himself with the inanity of commonplaces. Whatever he says is manly and invigorating in thought, and clear and forcible in expression. A word should be said of those digressions in which his Lives abound. 'I have always been pleased,' says Dryden, 'to see him and his imitator Montaigne, when they strike a little out of the common road; for we are sure to be the better for their wanderings. If we mark him more narrowly, we may observe that the great reason of his frequent starts is the variety of his learning; he knew so much of nature, was so vastly furnished with all the treasures of the mind, that he was uneasy to himself, and was forced, as I may say, to lay down some at every passage, and to scatter his riches as he went: like another Alexander or Adrian, he built a city or planted a colony in every part of his progress, and left behind him some memorial of his greatness.' (*Life of Plutarch*, by Dryden.)

The first Greek edition of the 'Moralia,' which is exceedingly incorrect, was printed by the elder Aldus, with the following title, 'Plutarchi Opuscula, lxxxxii.,' Gr., Venetiis, 1509, fol. It was afterwards printed at Basel, by Froben, 1542, fol., and 1574, fol. The only good edition of the 'Moralia' is that printed at Oxford, and edited by D. Wyttenbach, who laboured on it twenty-four years. This edition consists of six volumes of text (1795-1800), and two volumes of notes (1810-1821), 4to. There is a print of it which is generally bound in 5 vols. 8vo., with two volumes of notes. The remarks of Wyttenbach were printed at Leipzig, in 1821, in two vols. 8vo.

The first edition of all the works of Plutarch is by H. Stephens, Geneva, 1572, 13 vols. 8vo., which is said to be correctly printed. This edition was reprinted several times. A complete edition, Greek and Latin, appeared at Leipzig, 1774-1782, 12 vols. 8vo., with the name of J. J. Reiske, but Reiske did very little to it, for he died in 1774. An edition by J. C. Hutten, appeared at Tübingen, 1791-1805, 14 vols. 8vo. A good critical edition of all the works of Plutarch is still wanted.

The 'Moralia' have been translated into French by Amyot. Amyot's complete translation of all the works was reprinted at Paris by Didot, 1818-1820, 25 vols. 8vo. The 'Moralia' have been translated into German by Kaltwasser.

PLUTO (Πλούτων), more frequently called by the Greeks Hades (Ἅιδης), and by the Romans *Orcus* and *Dis*, was the brother of Zeus and Poseidon, and the deity that presided over the region where the departed souls of men were placed. Hades, which is also written without an aspirate, Ades, is a word of uncertain etymology. Pluto is supposed to be connected with the Greek word signifying wealth (πλοῦτος), since the precious metals are found beneath the earth's surface, below which the abode of Hades was generally placed. The Latin Dis has the same meaning. Orcus is probably connected with the words εἴργω and *arceo*, and may signify 'bound or restrained.'

Pluto is represented by the antient writers as a gloomy deity, inexorable to the prayers of mortals, and hated by the human race above all the gods. (*Il.*, ix. 159.) His wife was Persephone, called by the Romans Proserpina. [Proserpina.]

In the 'Iliad' (ix. 569; xx. 61; xxiii. 100) and in the 'Theogony' of Hesiod (455, 767), the abode of Hades is said, as has been already stated, to be beneath the earth; but in the 'Odyssey' it is placed in the regions of darkness beyond the stream of ocean. (*Od.*, x. 508; xii. 81.)

In later writers the word Hades also signifies the abode of the dead, as well as the deity who presided over it.

The temples and statues of Pluto appear to have been very few. Pausanias relates (i. 28, § 6), that there was a statue of Pluto in the temple of the Eumenides on the Areiopagus of Athens; and the same writer also informs us (v. 20, § 1) that there was a statue of this god in the temple at Olympia, but he mentions no temple sacred to Pluto in any part of Greece.

PLUTONIC. Rocks of igneous origin and antient geological date are thus designated in many modern works. In publications relating to the controversy between Wernerians and Huttonians, the former are often styled Neptunists, the latter Plutonists. In Brongniart's 'Tableau des Terrains,' these rocks are separated from volcanic rocks, on the hypothesis that the latter are specially rocks of fusion, but placed with them in one class of Typhonian rocks. Granite, syenite, porphyry, eurite, and pitchstone are Plutonic rocks. The term is not synonymous with the word Hypogene, as defined by Mr. Lyell.

PLUTUS (Πλοῦτος), the god of wealth, is said by Hesiod (*Theog.*, 969) to have been the son of Demeter and the hero Jasius. He appears as an actor in the comedy of Aristophanes named after him; but we have no particulars respecting his worship. In the temple of Fortune at Thebes, Plutus was represented as a child in the arms of Fortune (Paus., ix. 16, § 1), and at Thespeia in Bœotia there was a statue of Plutus placed by the side of one of Athena Ergane. (Paus., ix. 26, § 5.)

PLUVIA'LIS. [Plovers.]

PLYCTO'LOPHUS. [Psittacidæ.]

PLYCTOLOPHI'NÆ. [Psittacidæ.]

PLYMOUTH, a seaport, corporate, and market town in Devonshire, 192 miles in a direct line west-south-west of St. Paul's, London, and 216 miles from the General Post-Office, London, by the South-western Railroad to Basingstoke, and from thence by mail-road through Whitchurch, Andover, Amesbury, Wincanton, Ilminster, Exeter, and Ashburton; in 50° 17′ N. lat. and 4° 8′ W. long. It is the easternmost of the three towns which lie on the north shore of the Sound. The others are Stonehouse and Devonport. [Devonport; Stonehouse.]

Plymouth was originally inhabited by fishermen. By the Saxons it was called Tameorworth; after the Conquest it was called Sutton (*i.e.* South-town), which name is retained by an inlet of the Sound, Sutton Pool, on the shore of which the town is partly built. In the time of Edward I. the northern part of the town, built on the land of the priory of Plympton, was distinguished as Sutton-Prior, and the southern part, built on the estate of the Valletorts, as Sutton-Valletort. In the reign of Henry VI. these names were superseded by that of Plymouth, which the town still retains. Plymouth was attacked by the French in the reign of Edward III., but without success. In the reign of Henry IV. the attempt was repeated, and the town partly burnt, but the castle and the highest part of the town were not taken. In 1438, in the reign of Henry VI., the town was incorporated by charter, and walled in; but it is supposed to have been a borough by prescription at an earlier period. On the dissolution of the monasteries, the lordship of the town and other immunities of the priors of Plympton were granted to the mayor and corporation. In the reign of Elizabeth a new charter was bestowed on the corporation on the solicitation of Sir Francis Drake, who further benefited Plymouth by bringing water to the town from Dartmoor by a winding channel twenty-four miles in length. In A.D. 1579 and 1581 the town suffered much from the plague. In 1588 the Sound was the rendezvous of the fleet destined to oppose the Armada; and in 1596 of the fleet destined to attack Cadiz. In 1626 the plague again broke out, and carried off two thousand persons. In the civil war of Charles I. the town, which had embraced the parliamentary side, was besieged by the royalists under Prince Maurice, but held out until relieved by the earl of Essex (A.D. 1643). It was soon after attacked by the king in his march into Cornwall, and subsequently blockaded by Sir Richard Grenville, but both attempts failed of success.

The town of Plymouth is on the north side of Plymouth Sound, between the two great arms of that harbour, Catwater on the east, and Hamoaze on the west, but at some distance from both. The small inlet of Sutton Pool is close to the town on the east side, and Mill Bay, another inlet, not far from it on the west. On the point at the entrance to Sutton Pool is the citadel, and to the north of this lies the town, consisting of a number of streets, of which the older are irregularly laid out, while those of modern date are on a more regular plan. The limits of the borough comprise the two parishes of St. Andrew and Charles the Martyr, having a joint population, in 1831, of 31,080: part of each parish, lying beyond the corporation boundary, is not included in this statement. The older streets are narrow and ill built, and some of them steep. Up to the commencement of the present century little had been done in the way of local improvement, but since that period great improvements have been made. Building has been extensively carried on; many handsome houses have been built in the suburbs, a new and handsome road formed to connect Plymouth with Stonehouse, and several additions made to the public buildings. The town is well lighted with gas; the supply of water is under the direction of the corporation, and is still furnished by Sir F. Drake's channel or 'leat;' it is received in three large reservoirs, one of them belonging to government, and distributed by iron pipes. There were formerly many public conduits, but having become nuisances, they have been gradually removed; the last six in 1826. The surplus water turns several mills belonging to the corporation.

St. Andrew's church is a spacious structure of antient foundation and varied architecture, having a square embattled tower. In 1825 its interior was repaired and embellished at an expense of upwards of 4469*l.*, but the original order is preserved; it possesses a fine organ, will seat 2500 persons, and is lighted with gas. Charles church was begun just before the civil war of Charles I., but was not completed until after the Restoration, when the exuberant loyalty of the period led to its dedication to king Charles the Martyr. It is a neat building, with a square tower and well proportioned spire. There are two chapels-of-ease, one in each parish, besides three other episcopal places of worship, viz. a mariners' church, a chapel in the citadel, and a licensed room on the Hoe. There are besides chapels for Baptists (two), Independents, Presbyterians, Unitarians, Quakers, Wesleyan, Warrenite, and Bryanite Methodists, and other dissenters, and a Jews' synagogue. The foundation-stone of a new church in St. Andrew's parish, to be called Trinity church, was laid a few months since. There is a splendid hotel, with an assembly-room, and a theatre adjacent to it, both erected by the corporation at a heavy expense. The custom-house, the royal baths, the new hospital, the Athenæum, or building of the Plymouth Institution, the public library, the Freemasons' Hall, and the Mechanics' Institute, are also worthy of notice. The Guildhall is an irregular structure, comprehending the central watchhouse and the town prison. The grammar-school is a substantial stone building.

The harbour of Plymouth comprehends the Sound and its various arms. About fourteen miles south stands the Eddystone lighthouse, built in 1759, on a reef of rocks stretching north and south 100 fathoms, and forming a slope to the south-west. The Sound is a considerable inlet of the English Channel, three miles wide at the entrance from Penlee Point on the west to the opposite headland on the east, and extending inland about three miles to the citadel and town of Plymouth. On the western side of the Sound is Cawsand Bay. The coast all round, except just at the village of Cawsand on the west, and at the inlets of Mill Bay and Sutton Pool on the north, is rocky and abrupt, and the rocky island of St. Nicholas (sometimes called Drake's Island) rises out of the water not far from the north shore. The æstuary of the Tamar forms the harbour for the ships of war, and is called Hamoaze; it opens into the north-western corner of the Sound. The æstuary of the Plym or Lara forms another harbour, chiefly used for merchant vessels, and in time of war for transports, captured vessels, &c., and is called Catwater; it is capable of containing 1000 sail of such vessels. Here is also a wet and dry dock suited to the building of 74-gun ships. Catwater opens into the N.E. corner of the Sound, and has at its mouth the rocky promontory of Mount Batten, opposite Plymouth. It is not so deep as Hamoaze. Sutton Pool is a tide-harbour, also used by merchant vessels; and an act of parliament has just been obtained for the erection of a pier in Mill Bay, for the accommodation of the largest class of steam-ships at all times of the tide (1840). This pier has been determined on in consequence of the great number of steamers which now frequent the port. The harbour of Hamoaze is four miles long, and has a depth of water of fifteen fathoms at ebb tide; there are moorings for nearly one hundred sail of the line. The dock-yard [DEVONPORT] is on Hamoaze. The harbour was long exposed to the heavy sea which rolled into the Sound with gales from the southward, and great damage was at various times done. To remedy this a breakwater or dyke, formed of loose stones, was commenced A.D. 1812; it runs across the middle of the Sound, having a total length of 1700 yards, or nearly a mile, viz. 1000 yards in the centre, which runs in a direction nearly from east to west, with a continuation of 350 yards at each end, turning more to the north, and forming a considerable angle with the direction of the centre.* The efficiency of the breakwater as a protection to the harbour has been proved in several severe gales which have occurred since its commencement. The harbour is defended from hostile attack by the citadel of Plymouth, by the fortifications on the island of St. Nicholas, and by various other batteries.

The population of Plymouth, as well as of the adjacent towns of Stonehouse and Devonport, has increased very much during the present century, as appears from the following statement:—

	1801.	1811.	1821.	1831.
Plymouth . .	16,040	20,803	21,591	31,080
Stoke Damerall Parish (Devonport)	23,747	30,083	33,578	34,883
East Stonehouse .	3,407	5,174	6,043	9,511
	43,194	56,060	61,212	75,534

If we take the increase of the ten years 1321-31 as the basis of our calculation, we may estimate the present population of Plymouth at nearly 40,000; that of Devonport (which has not of late increased so fast) at 36,000; and that of Stonehouse at 12,000: making a total of 88,000. The trade of the town is important, as appears by the custom-house returns for the year 1839, which amounted to 90,000*l.* Besides the business arising from the dockyard at Devonport and the connected establishments, considerable trade is carried on with the West Indies, the Baltic, and the Mediterranean, and coastwise with London and other places; and there is an active fishery, especially of whiting and hake. The imports are timber and West India produce; the exports, manganese to Scotland, wool to Hull, and lead to London and Bristol. There are an extensive sail-cloth manufactory, a sugar refinery, a glass-house, a very large soap factory, and a starch factory. Granite, slate, limestone, and marble, are quarried in the neighbourhood. The limestone or marble of the Oreston quarries, on the shore of Catwater, opposite to Plymouth, was the material chiefly employed for the breakwater. Near these quarries is a beautiful iron-bridge of five elliptical arches over Catwater, built at the sole expense of the earl of Morley. In 1834 a floating steam-bridge was established across the Hamoaze between Devonport and Torpoint, which crosses regularly every quarter of an hour, and conveys the mail-coaches, carriages, horses, and passengers without the least delay or inconvenience. This communication has proved the greatest benefit to the neighbourhood. A railroad, to the extent of 24 miles, connects Plymouth from Sutton Pool to Prince Town, near the prison of war on Dartmoor. There are markets on Monday, Thursday, and Saturday; and two yearly fairs.

The town-council consists of 12 aldermen and 36 councillors; the borough is divided into six wards. Quarter-sessions and petty-sessions (twice a week) are held; and there is a court, entitled the mayor's court, or the borough court, for the trial of civil actions. The yearly revenue of the corporation, arising from tolls at the markets and fairs, from the rents of the mills, the royal hotel, the theatre, and other property belonging to the corporation, and from the water rents, is about 6700*l.* There is a heavy debt. The borough prison, when the inspectors made their second Report (dated 1836), was inadequate for its purpose and under bad management.

Plymouth returned members to parliament in the reigns of Edward I. and II.; and again in the reign of Henry IV., since which time it has regularly sent two. The mayor is the returning officer. The boundaries of the borough for parliamentary purposes were slightly enlarged by the Boundary Act. By the Reform Act, Devonport, with which Stonehouse was incorporated, was formed into a new parliamentary borough, returning two members. The number of voters registered for Plymouth in 1834-5 was 1571; in 1835-6, 1776; for Devonport at the same periods, 1870 and 2083.

The living of St. Andrew is a vicarage united with the chapelry of Pennycross, of the clear yearly value of 920*l.*; together with the patronage of the perpetual curacy of the chapel-of-ease, the clear yearly value of which is 148*l.* The living of Charles is a vicarage, the clear yearly value of which is 612*l.*; the value of the chapelry in this parish is 100*l.* per annum clear.

Among the educational institutions of Plymouth were, in

---

* The dimensions of the breakwater are, with the exception of the length, very variously given. In an account published by Johns, Devonport (1819-20), the breadth at the base is given at 210 feet, and 30 feet at the top where the depth of water at ebb tide is 30 feet. Mr. Wightwick gives the dimensions of the breakwater as follows:—breadth at the base 120 yards, at the top 16, length at the base 1760 yards, at the top (including the two arms) 1700; average height 14 yards; slope of the work towards the sea, three horizontal to one perpendicular.'

1833, in the parish of St. Andrew, the Orphans' Aid School, an endowed institution for the maintenance and education of orphans born in the borough, in which were 8 orphans; the Benevolent Institution for clothing and educating 60 girls; a grammar-school, partly endowed, with 50 boys; a new grammar-school, with 33 boys, instituted originally as a proprietary school; 41 other day or boarding and day schools; an infant-school, since given up, with 87 children, and numerous small schools for little children. There were also three Sunday-schools. In Charles parish were an endowed school, with 80 boys and 80 girls; Dame Hannah Rogers's Charity, with 52 girls; a Lancasterian school, with 176 boys and 120 girls; a day and Sunday school, with 60 girls, called the Household of Faith; fifteen other day-schools, and two Sunday-schools. The whole number of children under instruction in the two parishes was returned at about 3200, besides those in the Sunday-schools.

There are a Mechanics' Institute; the Plymouth Institution for the promotion of arts, science, and literature; the Natural History Society of Devon and Cornwall; a public library containing more than 6000 volumes; baths, and a theatre. Races are annually held in a meadow near the town, and a regatta in the Sound. There are an hospital for merchant seamen, a public dispensary, an eye infirmary, and several other charities. There are prisons for prisoners of war at Mill Bay, capable of containing 3000 men.

PLYMOUTH, AMERICA. [Massachusetts.]

PLYMPTON. [Devonshire.]

PNEUMATICI (*οἱ πνευματικοί*), a medical sect founded by Athenæus about the middle or end of the first century A.D. [Athenæus.] Their principal doctrines have been noticed in the life of their founder, and the following is a list of the physicians that belonged to their number:—Archigenes (Galen, *Introduct.*, cap. 9, p. 699, ed. Kühn), Herodotus (Galen, *De Simplic. Medicam. Temper. ac Facultat.*, lib. i., cap. 29, p. 432, and *De Different. Puls.*, lib. iv., cap. 11, p. 751), Agathinus (Galen, *De Dignose. Puls.*, lib. i., cap. 3, p. 787), Magnus (Galen, *De Different. Puls.*, lib. iii., cap. 2, p. 646), Theodorus (Diog. Laërt., *Vit. Philos.*, lib. ii., § 104). To these the name of Athenæus has been added by Le Clerc (*Hist. de la Med.*, p. 508, &c., ed. 1723), Wigan (*Præfat. in Aret.*), Barchusen (*Hist. Medic.*, p. 269), Schulze (*Compend. Hist. Medic.*, Halæ, 1744, p. 332), and Haller (*Biblioth. Medic. Pract.*, tom. i., p. 192, &c.); but the passages brought forward in support of this opinion (for it rests only on internal evidence) are considered to be insufficient to prove the point by Petit (*Præfat. ad Comment. in Aret.*), Osterhausen (*Dissert. Inaugur. de Sectæ Pneumaticorum Medicorum Historia*, Altorf., 1791, 8vo.), and Ackermann (*De Aretæo*, in edit. Kühn). The sect appears to have existed but a short time, namely, from the reign of Vespasian to Antoninus Pius, and never to have enjoyed any great celebrity. For further information concerning it the reader may consult Wigan, Ackermann, and especially Osterhausen, *locis cit.*

PNEUMATICS. This name is given to that part of physics in which are contemplated the mechanical properties of elastic fluids, principally atmospherical air. The word is derived from *πνεῦμα*, 'breath or spirit,' and pneumatology is a term which was once applied to the division of science now called metaphysics.

The mechanical properties of air appear to have been, to a certain extent, known to the antients. Aristotle must have been aware of its materiality, and of its tendency to descend towards the earth, like other heavy bodies, for he observes that if a bladder be filled with air, it weighs more than when empty: the observation proves at least that he had the idea, but it may be doubted whether or not he ever made the experiment, since it is not probable that he had the means of weighing the full bladder in vacuo, or that he could keep it distended when the air was extracted from it. The invention of a species of forcing-pump for raising water, and of instruments for producing sounds by the passage of air through orifices in tubes, both of which are ascribed by Vitruvius (lib. ix., x.) to Ctesibius, who lived about 130 years B.C., are proofs that the elastic force of compressed air must have been then apprehended and made subservient to purposes connected with practical utility.

The ascent of water in pumps, on raising the piston, must have been for ages observed, without a suspicion being entertained of the cause; and the principle that the existence of a vacuum was impossible, was held to afford a sufficient explanation of the phenomenon. Even Galileo, when made aware, by the formation of a vacuum between the piston and the water when the latter was at its greatest height in a pump, that the principle was unfounded, had recourse to another which was equally remote from the truth; for he is said to have ascribed the ascent of the water to the attraction of the piston, and to have accounted for the height of the column never exceeding a certain quantity (about 34 feet) by a supposed equilibrium between the weight of the column and the attractive power of the piston. The steps by which Torricelli arrived at the discovery of the true cause of the phenomenon, and, at the same time, the determination of the pressure of the atmosphere by the weight of the column of mercury supported in a tube closed at the upper extremity, are mentioned under the word Barometer.

Soon after the commencement of the seventeenth century, the idea of ascertaining with precision the state of bodies with respect to temperature by the expansion of fluids when acted on by heat, is said to have occurred to the members of the Academy del Cimento at Florence; and this gave rise to the invention of an instrument of great importance, as well for many occasions of ordinary life, as for the purposes of pneumatical science. [Thermometer.]

The desire of perfecting the theory for determining the heights of mountains by the barometer, led to numerous researches in order to ascertain the relations between the condensation of air and the forces compressing it, and also to discover the effects produced by variations of temperature. About the year 1660, Boyle in England and Mariotte in France determined from experiments, that when the temperature was constant, the density of air was proportional to the compressing force; but it was not till a century afterwards that De Luc determined the expansion consequent upon given increments of temperature.

In the beginning of the eighteenth century, steam began to be employed as a moving-power for pumps and other machinery. The law of the resistance of the air to bodies moving in it was discovered by Sir Isaac Newton; but the intensity of this resistance against military projectiles was first determined, for the inferior velocities, by Robins, in 1740; and Dr. Hutton subsequently obtained a formula which, with perhaps sufficient correctness, may be employed with any velocity whatever. The expansion of fired gunpowder has been determined from the researches of Robins, Euler, and Hutton; and that of steam has been investigated by Dalton in England, and by Prony, Arago, and other members of the Institute, in France.

If a fluid be conceived to be perfectly elastic, it is evident that it can be made to occupy a given volume only by being confined within a close vessel, or by the pressure of a circumambient fluid. In the latter case it is easy to perceive that while the temperature of the elastic fluid remains the same, the spaces occupied by it will be diminished when the compressing force is increased, and increased when the latter is diminished; and that the density, or degree of closeness of the particles, will vary directly with the changes of volume. Now the compressing forces which are made to act on the surface of an elastic fluid are usually estimated in terms of the pressure exerted by a vertical column of the atmosphere, its base being equal to some unit of superficies, as one square inch or foot. Whatever be the constitution of such column, its weight or pressure is known, in a given state of the atmosphere, by direct experiment, and this is usually designated the pressure of one atmosphere: the same pressure is also frequently expressed by the height of the column of mercury which is supported in a barometer-tube by the counteracting weight of the atmospherical column.

A simple experiment suffices to show the relation between the density and elasticity of a fluid and the compressing force. Let mercury be poured into a bent tube open at one end and closed at the other; the sum of the weights of the column of mercury, and of the atmosphere above it in the open tube, will reduce the air in the closed tube to a volume less than that which it previously occupied. Let, then, more mercury be added, and the volume of air will be still further reduced at every addition of mercury; and it will be found that the volumes of air vary inversely as the sums of the weights of the mercury and atmosphere. Therefore, since the density of an elastic fluid is inversely proportional to the space it occupies, it follows that the densities are directly proportional to the compressing weights; and since the weights of the mercury and atmosphere together, in the open tube, are balanced by the elastic power of the condensed air in the close tube, that elastic force is also directly proportional to the compressing force, that is, to the density. [AIR.] This is the law of Boyle and Mariotte, and though it cannot be said to be absolutely correct, it is very generally employed.

The following table, extracted from the results of the experiments made by MM. Prony, Arago, and others, exhibits the volumes and elasticities of a given quantity of atmospherical air under different pressures, the temperature being nearly constant, and expressed by 14° of the centigrade thermometer (57·2° Fahrenheit), and, as far as it extends, it confirms the law above mentioned. The first of the columns expresses the pressure or elasticity in multiples of the weight of an atmospherical column; the second expresses the same by the height, in inches, of the column of mercury supported in a barometer tube; and the third column contains the corresponding volumes.

Atmospheres.	Inches, Eng.	Volumes.
1	30	1·0000
5	150	·1989
11·3	339	·0884
16·5	495	·0601
21·7	651	·0457
24	720	·0411
27	810	·0369

The law being admitted, it may be proved that the particles of an elastic fluid repel each other with a force which varies inversely as the distance between them. For let the volume of fluid be in the form of a cube, and let the compressing force act perpendicularly on one of its faces; then, if d represent the distance between every two nearest particles of fluid, the number of particles in the surface pressed will vary as $\frac{1}{d^2}$. Now assume that the repulsive force (perpendicularly to that surface) between every two nearest particles in the volume varies as d^n; then the whole repulsive force on that surface, and, consequently, the compressing force, will vary as d^{n-2}. If D represent the density of the fluid, d will vary as $\frac{1}{D^{\frac{1}{3}}}$, or $D^{-\frac{1}{3}}$; therefore, substituting $D^{-\frac{1}{3}}$ for d in the last expression, the whole repulsive force varies as $D^{-\frac{1}{3}(n-2)}$. But, agreeably to the law above mentioned, the compressing force varies as D; therefore the exponent $-\frac{1}{3}(n-2)$ must be equal to unity, and hence $n = -1$. It follows therefore that the repulsive force between every two nearest particles varies as d^{-1}, or inversely as the distances of those particles from each other. Sir I. Newton however observes (lib. ii., prop. 23, schol.) that this law holds good only when the repulsive power of any particle does not extend much beyond those which are nearest to it.

If P and P′ represent the pressures exercised upon a square unit of the superficies bounding an elastic fluid, and the volumes of the fluid under those pressures be V and V′; also if the densities be D and D′ respectively, we shall have

$$P : P' :: V' : V, \text{ or } P.V = P'.V',$$
$$\text{and } P : P' :: D : D', \text{ or } P.D' = P'.D;$$

whence, by equality of ratios,

$$V : V' :: D' : D, \text{ or } D.V = D'.V'.$$

Considerable difficulty is found in determining the specific gravities of gases with precision, and different experimenters have obtained results which do not exactly agree. The value generally adopted for air, when the height of the column of mercury in the barometer is 30 inches, and the temperature by Fahrenheit's thermometer is 55°, is 1·22 ounces avoirdupois, or 534 grains troy. The experiments of Mr. Dalton have led to the conclusion that the weight of a cubic foot of steam when at the temperature of boiling water, and the height of the barometrical column is 30 inches, is 253 grains troy; by others it has been found to be 254·7 grains; and it appears that within considerable limits the expansion of the volume of any gas is proportional to the increments of temperature, measured by the degrees of the thermometer. The absolute value of the expansion is not precisely known; that of air is stated to be equal to about $\frac{1}{480}$, and that of steam about $\frac{1}{459}$ of the volume, for one degree of Fahrenheit's thermometer. [AIR.]

The following table, from the observations of MM. Dulong and Petit, exhibits the volumes assumed by a given quantity of air at different temperatures between the boiling-point and near the freezing-point of mercury:—

Temperatures.	Volumes.
−33°	0·8650
32	1·0000
212	1·3750
302	1·5576
392	1·7389
482	1·9189
572	2·0976
680	2·3125

Now to determine the elastic force, or the equivalent pressure, of air in terms of its density and temperature; let V be the volume of a body of air at any given temperature, suppose 55° (Fahrenheit), and let p be the corresponding pressure, or elastic force, measured by the weight of the column of mercury in the barometer, or by its height, and let d be the number of degrees of temperature above or below 55°. Then, since $\frac{1}{480} = {\cdot}0021$, we have $V(1 \pm {\cdot}0021d)$ for the volume of the air at the temperature $55° \pm d$. Let also D represent the density or specific gravity of the air at the temperature 55°; then, since the density is inversely proportional to the volume, we have the density at the temperature $55° \pm d$ equal to $\frac{D}{1 \pm {\cdot}0021d}$; let this be represented by D′. Now, if the pressure p be varied and become P without changing the temperature; since then the pressure, or elastic force, is proportional to the density, we have $p : P :: D' : D''$ (= the density of the air under the pressure P); consequently $P = \frac{D''p}{D'}$, or $= \frac{D''p(1 \pm {\cdot}0021d)}{D}$. And, if p be expressed by the weight of a column of mercury whose base is one square inch (= 14·75 pounds), this value of P is the required pressure upon a square inch of the surface of the air.

The density of an elastic fluid being proportional to the force which compresses it, and the volume increasing proportionally to the temperature; it follows that the density of an elastic fluid varies directly as the compressing force and inversely as the temperature.

From experiments it has been concluded that, while steam is in contact with the water from which it is formed, its expansive force increases in a geometrical progression; when its temperature is increased, in an arithmetical progression; but the relation between the elastic force of this gas and its temperature, in that state, is as yet far from being certainly known. Under the word ELASTICITY is given a table of the elastic forces of steam at temperatures between the freezing and boiling states of water; and the following table, extracted from those which have been formed from the results of the experiments of Mr. Dalton, Dr. Ure, and the members of the French Institute, may also be useful as a means of affording a near estimate of the force at high temperatures. The first column contains the temperature of the water and steam in degrees of Fahrenheit's thermometer; the second is the measure of the expansive force by the number of inches in the height of the column of mercury which on a given superficies would counterbalance it; and the third, the like measure expressed by multiples of the weight of the atmospherical column when the air is in its ordinary state.

Temperature.	Inches, English.	Atmospheres.
212°	30	1
220	35·54	1·18
240	51·7	1·72
260	72·3	2·41

408	541·5	18·05
419	613·2	20·44
435	719·8	23·994

When steam is not in contact with the water from whence it is formed, and when it is subject to a constant pressure under which it may expand in every direction (as when it is formed in the atmosphere), an increase of temperature will not produce an increase of density, but merely of its elastic power. Now, if we suppose steam to expand $\frac{1}{459}$

or ·00218 of its volume for an increment of temperature expressed by one degree (Fahrenheit); and it be admitted from the experiments of Mr. Dalton that a cubic foot of water produces 1711 cubic feet of steam at a temperature equal to 212° (boiling water):—Then, letting V represent the volume of steam at a temperature expressed by zero, we have $1·462\,V = 1711$; whence $V = 1170·3$: and, if t represent the given temperature in degrees of Fahrenheit's thermometer, $(1 + ·00218\,t)\,V$, or $1170·3 + 2·55\,t$, will express the volume of the steam at the temperature t, when subject to a constant pressure.

But if the steam is incapable of changing its volume, as when it is contained in a close vessel, the elastic force increases by an increase of temperature in the same proportion as the volume would have increased under a constant pressure; consequently the elastic force at the temperature 212° being represented by 30 inches (the height of the counterbalancing mercurial column), we have

$$1711 : 1170·3 + 2·55t :: 30 \text{ in.} : 20·52 + ·0447t;$$

and the last term of the proportion expresses, in inches, the height of the mercurial column equivalent to the elasticity at the temperature t; the volume of the steam being equal to 1711 cubic feet, as at the temperature = 212°. Let this elasticity be represented by E; then the volumes of any given quantity of elastic fluid, at equal temperatures, being inversely proportional to the pressures by which they are prevented from expanding, we have the following proportion:—

As any given compressing force (represented by the height of the mercurial column corresponding to some temperature t in the above table), is to the elastic force or pressure (= E) due to that temperature t, when the volume of the steam = 1711; so are 1711 cubic feet (= the volume of steam produced by a cubic foot of water at 212° under a constant pressure equal to the atmosphere), to the volume (in cubic feet) of the steam produced by a cubic foot of water under the given compressing force. Let this be represented by v.

Now the quantities of matter being the same, the specific gravities of bodies are inversely proportional to their volumes; and the specific gravity, or weight of a cubic foot, of steam being known from experiment to be 254·7 grains, when the cubic foot of water produces 1711 cubic feet of steam, we have

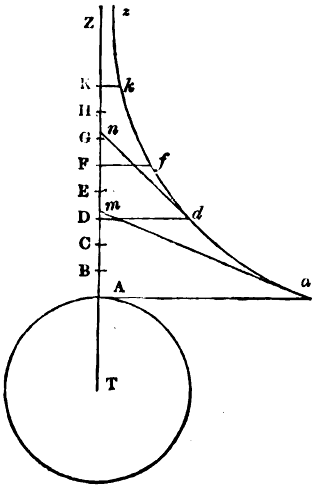
$$v : 1711 :: 254·7 : \frac{435792}{v} :$$

and the last term is the specific gravity, or weight in grains, of a cubic foot of steam at a given temperature and under a given pressure.

Mr. Robins found that the volume of air disengaged from gunpowder is equal to about 244 times the volume of the powder itself; and that its expansive force, when increased by the heat which is generated at the time of the explosion, is about 1000 times as great as the pressure of the atmosphere in its ordinary state. It must consequently exert a pressure against a cannon-ball, and the interior of the chamber of the gun, equal to nearly 15,000 pounds upon every square inch of the surface upon which it acts. Both D. Bernouilli and Euler however make this pressure still greater.

The fact that the density of air varies with the compressing force is sufficient to show that the atmosphere about the earth cannot be of uniform density; and it is also evident that the density must diminish from the surface of the earth upwards, according to some law depending on the height of any point above the earth, or rather upon the weight of the mass of air above that point. It might, at first, be supposed that the atmosphere would extend upwards to a height at which the centrifugal force of the particles of air (by the diurnal revolution) is equal to the force of gravitation; and it is shown by Poisson (*Traité de Mécanique*, tom. ii., 619) that, conformably to this principle, the height of the atmosphere at the equator should be equal to about five times the semi-diameter of the earth. But it is probable that, long before this height is attained, the air loses its elasticity by the cold in the upper regions, or that its expansion is destroyed by the pressure of the ethereal fluid which is diffused through infinite space. By the duration of twilight it is inferred that the atmosphere is capable of reflecting the sun's rays at the height of about 45 miles above the earth, and it is probable that some light is reflected from a still more elevated region.

In order to determine the law by which the density of the atmosphere diminishes at increasing distances from the earth's surface, on the supposition that the action of gravity and the temperature of the air are constant, let T be the centre of the earth, and let AZ be the height of a very slender column of air extending vertically upwards to the top of the atmosphere. Also let the atmosphere be divided into an infinite number of concentric strata of equal thicknesses, which latter represent by AB, BC, CD, &c.; and, as these thicknesses are small, let the density of the air in each stratum be uniform and equal to that which is due to the weight of all the strata above it.



Let d_1, d_2, d_3, &c. represent the densities of the several strata whose heights are AB, BC, CD, &c.; these terms may also represent the weights of the slender columns AB, BC, CD, &c.: consequently the weights of the columns AB, AC, AD, &c. may be respectively represented by d_1, $d_1 + d_2$, $d_1 + d_2 + d_3$, &c. Then, the density in each stratum being proportional to the weight, or sum of the densities, of all above it, we have

$$d_1 : d_2 + d_3 + d_4 + d_5 + \&c. :: d_2 : d_3 + d_4 + d_5 + \&c. \qquad \text{(I)}$$

In like manner

$$d_2 : d_3 + d_4 + d_5 + d_6 + \&c. :: d_3 : d_4 + d_5 + d_6 + \&c. \qquad \text{(II)}$$

or, by composition,

$$d_2 : d_2 + d_3 + d_4 + d_5 + \&c. :: d_3 : d_3 + d_4 + d_5 + \&c. \qquad \text{(III)}$$

In like manner

$$d_3 : d_3 + d_4 + d_5 + \&c. :: d_4 : d_4 + d_5 + d_6 + \&c. \qquad \text{(IV)}$$

Then, from (I) and (III), by equality of ratios, we have

$$d_1 : d_2 :: d_2 : d_3.$$

And, from (II) and (IV), by equality of ratios, we have

$$d_2 : d_3 :: d_3 : d_4;$$

and so on.

Thus d_1, d_2, d_3, d_4, &c. are in a geometrical progression decreasing.

Now AB, AC, AD, &c. form an arithmetical progression increasing; or, reckoning both the heights and the densities from any point, as K, downwards, the former (that is, KH, KG, KF, &c.) form an arithmetical progression, and the densities in KH, HG, GF, &c. form a geometrical progression, both increasing. But a series of numbers in an arithmetical progression being made to correspond to a series in geometrical progression, the former numbers are logarithms of the latter; and thus the distances KH, KG, KF, &c. may be considered as representing the logarithms of the densities in the strata KH, HG, GF, &c. respectively.

Hence, if there existed a table of logarithms formed on the two series just mentioned, the height of any point, as C, above another, as A, would be equal to the difference between the logarithms of the densities of the air at those points; or by the nature of logarithms, we should have AC = $\log. \frac{dens.\ at\ A}{dens.\ at\ C}$. But such a table is unnecessary, since, from the properties of logarithms and of the logarithmic curve, the value of AC may be found by means of the common tables. Imagine any point K to be the origin of the abscissæ (represented by x) on the vertical line ZA; and imagine any horizontal ordinates Kk, Ff, &c. (represented by y) to be drawn; then, if KF, KD, &c. be proportional to the logarithms of Ff, Dd, &c., the line $adfk$, &c. is called the logarithmic curve, and its equation is $\log. y = x \log. a$, or $y = a^x$ [Logarithmic Curve], where a is some constant which is called the base of the system of logarithms appertaining to the particular curve.

Now it has been demonstrated by mathematicians, that if tangents am, dn, &c. be drawn from any points in the curve, the subtangents Am, Dn, &c. will be equal to one another; and that the area comprehended between the infinite branch az of the curve, its asymptote AZ, and any ordinate Aa, is equal to the product of the constant subtangent, or modulus of the curve, and that ordinate: hence the area between Aa and the infinitely remote summit Z is equal to Aa × Am. Also, by the nature of logarithms, the logarithms of the same natural number in different systems of logarithms bear to one another the same proportion as the moduli of those systems. We have therefore only to find the value of the subtangent Am, or modulus, for what may be called the atmospherical logarithms; and, from the last-mentioned property, the above value of AC may be transformed into an expression containing common logarithms.

Let h denote the height of a homogeneous atmosphere whose density is equal to that of the real atmosphere at the surface of the earth, which density is represented by the line Aa in the above diagram; then h × Aa will represent the weight of such homogeneous atmosphere, or its pressure on the point A. But the area between Z A, Aa, and the curve being supposed to be made up of the infinite number of ordinates Aa, Dd, Ff, &c., which, severally, represent the densities of the air at the points A, D, F, &c. in the infinitely high column A Z of atmospherical air; that area, viz. Aa × Am, may represent the weight of such column, or the pressure of the real atmosphere on the point A; this being made equal to the former pressure, it is evident that we shall have Am = h. Thus the height of a homogeneous atmosphere exercising at A the same pressure as the real atmosphere, will be the subtangent, or modulus, of the atmospherical logarithms. The value of h is determined by a proportion in which the heights of the column of homogeneous air, and the column of mercury which holds it in equilibrio, are to one another inversely as the specific gravities of the two fluids. [Hydrostatics.] Now the specific gravities of air and mercury being, respectively, 1·22 and 13568; and the height of the column of mercury in the barometer being 30 inches when the temperature is expressed by 55° (Fahrenheit), we get 27803 feet, or 4634 fathoms for the value of h. Then the modulus of the common logarithms being 0·43429, we have

·43429 : 4634 : : common log. $\frac{density\ at\ A}{density\ at\ C}$: 10670 com. log. $\frac{dens.\ at\ A}{dens.\ at\ C}$; and this last term is the equivalent of the above expression for AC.

The height of the column of mercury which is supported by the pressure of the atmosphere varying directly with that pressure; it follows that we may substitute in the last expression the heights of the mercurial columns at A and C for the densities of the air at those points, and thus we have 10670 com. log. $\frac{height\ of\ merc.\ at\ A}{height\ of\ merc.\ at\ C}$ for the value of A C in fathoms. Therefore the heights of the columns of mercury being observed at any two places, as A and C, the height of C above A can be found. [Barometer.] But the factor 10670 may be changed into the more convenient number 10000 by an alteration in the temperature (55° Fahrenheit) on which the former number depends. By experiment it has been ascertained, that if the altitude of one place above another be computed from the above formula, it will vary by $\frac{1}{435}$ of its value for each degree by which the mean of the temperatures at the two stations differs from 55°. Now $\frac{10670}{435} = 24{\cdot}5$ nearly, the variation, in fathoms, for one degree; consequently 24·5: 670 (= the excess of 10670 above 10000) : : 1° : 27° nearly; and therefore 55°−27°, or 28°, is the temperature at which the expression 10000 com. log. $\frac{height\ of\ merc.\ at\ A}{height\ of\ merc.\ at\ C}$ gives the height of C above A in fathoms; and of course this value must be increased or diminished by $\frac{1}{435}$ part of itself for each degree above or below 28° in the mean of the temperatures observed at A and C. [Heights, Measurement of.]

The mountain-barometer, as it is called, is usually provided with an adjusting screw, by which the surface of the mercury in the cistern may be made to coincide with the zero of the scale of inches by which the height of the column is expressed; but those of a more portable kind have not that adjusting screw, and then a correction must be made for the error of the scale. For this purpose, the ratio between the area of the bore of the tube and the interior area of the cistern must be found (it is usually given by the maker of the instrument); let it be as 1 to m: this is also the ratio between the rise or fall of the mercury in the cistern and the corresponding fall or rise of that in the tube. When the surface of the mercury in the cistern happens to coincide with the zero of the scale of inches, the height of the column in the tube is correctly expressed by the scale, and the top of the column is, in that case, called the neutral point, no correction being then necessary. In other cases add $\frac{1}{m}$ of the height shown by the scale to that height, if the latter is greater than the neutral height, or subtract if less; the sum, or difference, is the correct height of the mercury in the tube above the surface of that in the cistern.

Water boils when the elastic power of the vapour formed from it is equal to the incumbent pressure; and consequently the temperature at which the boiling takes place in the open air will depend upon the weight of the atmospherical column above it. Therefore, since this weight becomes less as the station is more elevated, it is evident that water will boil at a lower temperature on a mountain than on the plain at its foot; and the Rev. Mr. Wollaston constructed an instrument called a thermometrical barometer, by which, on the principle just mentioned, the relative heights of stations can be found. A tube containing the mercury is provided with a graduated scale, and, when used, the bulb is placed in a vessel of water, which is made to boil by means of a spirit-lamp.

In order to determine the heights of stations merely by the knowledge of the temperature at which water boils, the formula $F = \left(\frac{t + 75^\circ}{85}\right)^6$ given by Mr. Tredgold, might be employed. Here t is the temperature of the boiling water at the station, expressed in degrees of the centigrade thermometer; F is the measure of the elastic force of the steam at the temperature t under the pressure of the atmosphere, and is expressed by the corresponding height, in centimetres, of the column of mercury in a barometer. This height being thus determined at each of the two stations, as A and C, the difference of the logarithms of the heights being multiplied by 10,000 will give the approximate height AC, which may be then corrected as above.

The velocity with which air flows into a vacuum through an aperture in a vessel follows the same law as water or any other non-elastic fluid [Hydrodynamics]; for though, in the former case, the quantity of air passing through the orifice in a given time varies with the density of that which successively comes to the orifice, yet the pressure by which the air is forced out varying in the same proportion, the velocity, by dynamics, remains constant. Hence we find that a column of air, in its ordinary state, extending to the top of the atmosphere, rushes through an orifice into a vacuum with a velocity (=1339 feet in a second) equal to that with which a heavy body would fall through a height equal to that of a homogeneous atmosphere.

The law is the same, whether we consider the air to act only by its weight, or whether it be confined in a vessel and the efflux be produced by the elasticity. For, the air in the vessel being in the ordinary state of the atmosphere, the pressure against every point on the interior surface is equal to the pressure of the atmosphere by which, if not otherwise confined, it would be kept in its actual state; consequently it begins to flow from the orifice with the same velocity as if it had been impelled by the weight of the whole column of atmosphere above the orifice, that is, with the velocity due to the descent of a body from a height equal to that of a homogeneous atmosphere. After this moment, the density of the air in the vessel diminishing, its elasticity diminishes with it, and consequently the power of motion is diminished in the same ratio as the density; therefore the velocity remains constant. It may be added also that, since the density of air increases with the pressure, an additional pressure on the fluid in a vessel will not in crease the velocity of the efflux. But the law just mentioned only holds good when the vacuum is supposed to remain perfect on the exterior of the orifice; for, if the air be received in a vessel, it will expand in that vessel and re-act against the effluent air at the orifice, thus diminishing the velocity till the latter finally becomes equal to zero; and this will take place when the air has attained the same density in the two vessels.

If the effluent air be of a given density, but not the same as in the ordinary state of the atmosphere, the force by which it would be made to flow into a vacuum must be determined by the above equation $PD' = P'D$; where P is the pressure (or weight of the column) of the ordinary atmosphere, and D its density at the earth's surface; D′ is the given density and P′ is the required pressure or force by which that air would be impelled through the orifice. Now if air in the ordinary state be allowed to rush into a vessel containing air less dense than itself, and the velocity of efflux be required, the moving force will be the difference between that with which the ordinary air is driven through the orifice and that with which the rarer air would be so driven; that is, it may be represented by $P-P'$; then the velocities of efflux being as the square roots of the forces [Hydrodynamics], if the velocity due to the force P is given, the required velocity at the commencement of the efflux may be found.

The determination of the velocity with which steam or any other elastic fluid rushes into a vacuum, or into a fluid of less density than itself, is made in the same manner as for air. Thus, knowing the temperature of steam, and consequently its elasticity, or the equivalent pressure, we can find the height of a homogeneous atmosphere which would produce the same pressure; and then the velocity with which the steam flows into a vacuum would be equal to that acquired by a body in falling down the height of such atmosphere. But if the steam is to flow into any elastic fluid of less density than itself, the height of the homogeneous atmosphere must correspond to the difference of the pressures arising from the different elasticities of the two fluids.

In order to find the time during which air, being in the ordinary state, must flow through an orifice into an exhausted vessel before the air in the latter acquires any given density D′; let V be the interior volume of the vessel which is to receive the air, and A be the area of the orifice; also let t be the required time. Then $d\,(V.D')$ or $V.dD'$ represents the small quantity of air which may enter the vessel V in the time dt at the commencement of the efflux. Now, let D be the ordinary density of the air, h the height of the homogeneous atmosphere, then $\sqrt{2gh}$ [Hydrodynamics] will be the initial velocity. But, P being the force by which the ordinary air is impelled through the orifice, from the equation $P.D'=P'D$ we have $P'=\frac{P.D'}{D}$, and $P-\frac{P.D'}{D}$ becomes the force by which the air is impelled through the orifice at the end of the time t, or when the density is D′, and the velocities being proportional to the square roots of the forces, we have the velocity at the end of the time t equal to $\sqrt{\left\{2gh\left(1-\frac{D'}{D}\right)\right\}}$; this being multiplied by the density, by the area of the orifice, and by dt, gives $A\sqrt{\{2ghD(D-D')\}}dt$ for the small quantity of air which, during the element dt of time, and at the end of the time t, flows into the vessel. The velocities being constant, the quantities that flow during the time dt are equal to one another; hence, equating this expression with VdD' above, we get $dt=\frac{V}{A\sqrt{2ghD}}\,\frac{dD'}{\sqrt{(D-D')}}$. This equation being integrated gives $t=\frac{2V}{A\sqrt{2ghD}}(D-D')^{\frac{1}{2}}+const.$ The constant is determined by considering that $t=0$ when $D'=0$, which gives $const.=\sqrt{D}$, and thus the value of t is found.

It is shown under the word Air-Pump that the density of the air in a receiver becomes diminished in a geometrical progression, after successive strokes of the piston. Now the common ratio of this progression may be expressed algebraically by the term $\frac{v}{v+v'}$, where v is the volume of the receiver, and v' that of the barrel; and, if D be the density of the air in the receiver when the process of exhaustion is commenced, we shall have evidently $D\,\frac{v^n}{(v+v')^n}$ for the density of the air in the receiver after n strokes. Hence this density can be found when the number of strokes is given; or, reducing the equation, we may find n, the number of strokes which would be necessary in order to reduce the air in the receiver to any given density.

For the pressure and resistance of the air against bodies, see Aero-Dynamics and Gunnery; and for aerial navigation, see Balloon.

PNEUMOBRANCHIA'TA, Lamarck's second section of his order *Gasteropoda*, containing the *Limacinea*, or Snails.

PNEUMODERMON. [Pteropoda.]

PNEUMO'NIA. [Lungs, Diseases of.]

PNEUSTOI'DEA, Fitzinger's name for a family of Saurians, formed from *Lyriocephalus* and *Pneustes*, Merrem, and *Phrynocephalus*, Kaup. This family Fitzinger approximates to that of the Cameleons.

PO, BASIN OF THE. The river Po, called Padus and Eridanus by the Romans, rises from two springs, in about 44° 40′ N. lat., 7° E. long., on the eastern side of Mount Viso, a splendid mountain pyramid 12,580 feet high, the upper part of which is covered with perpetual snow. The sources of the Po are about 6000 feet above the sea. Flowing first east and then north-east, through a deep valley called Val d'Oro, the Po receives on its left bank the Chisone and other streams from the valleys of Pignerol and of the Valdenses; and on its right bank the Vraita, the Maira, and the Grana, which, rising in the recesses of the Maritime Alps, flow in a north-east direction through the open country of Saluzzo, and join the Po in succession above the town of Carignano, from whence the river flows nearly due north to Turin, through a broad valley bounded by the offsets of the Cottian Alps on the west and the hills of Monferrato on the east. Passing Turin, where it is crossed by a handsome stone bridge, the Po receives on its left bank the Dora Riparia from the valley of Susa and Mount Cenis, and afterwards the Stura from the valley of Lanzo, a romantic district among the Alps north-west of Turin. The river now inclines to the north-east, receives the Orca from the north, and passing by the town of Chivasso, turns to the east or east by south, in which general direction it continues to flow for the rest of its course to the sea, making however numerous windings. Below Chivasso the Po receives from the north the Dora Baltea, with all the drainage of the large valley of Aosta, and about thirty miles farther the Sesia, a considerable stream, which rises in the glaciers of Mount Rosa, and which, after draining the Val di Sesia, an Alpine valley, enters the plains of Vercelli, receives the Cervo and other streams, and after a course of about ninety miles enters the Po below the town of Casalè. The Po here makes a bend to the south, but on reaching Valenza resumes its eastern course. In all its course from Carignano to Valenza, for a length of nearly eighty miles, the Po receives no affluents of any importance on its right bank, being skirted all along on that side by the hills of Monferrato, owing to which the river describes a kind of semicircle. But to the south of those hills, and between them and the Ligurian Apennines, flows the Tanaro, a large stream which rises near Ormea in the Maritime Alps, and flowing northwards, receives the Ellero, Pesio, and Gesso, and the Stura from Cuneo (Stura is the name of several rivers of Piedmont), and after passing by Cherasco and Alba turns to the east, receiving the draining of the hills of Lower Monferrato on one side and of the Ligurian Apennines on the other. [Monferrato.] The Tanaro flows by Asti, the principal town of Monferrato, receives the Belbo from the south, and farther on the Bormida, swelled by the Orba from the mountains of La Bocchetta, after which it flows through the plains of Alessandria and Marengo, and enters the Po about eight miles below Valenza, after a tortuous course of about 150 miles, in which it describes a segment of a circle nearly parallel to that described by the Po, being separated from the latter river by the hills of Lower Monferrato.

After receiving the Tanaro, the Po continues its course in an easterly direction through the wide plain of Lombardy, receiving on its right or southern bank the Scrivia from Tortona and the Staffora from Voghera, and on its left or northern bank the Agogna and the Terdoppio from Novara. Between Voghera and Piacenza several offsets of the

Ligurian Apennines approach close to the southern bank of the Po, whose only affluent of any importance from that quarter is the Trebbia, a mountain torrent which swells greatly in the rainy season, but is shallow in time of drought. [Parma, Duchy of.] There is a marked difference between the character of the southern affluents of the Po east of the Tanaro and those which come from the north. The latter are deep perennial rivers, being fed by the glaciers of the Alps, but the others partake more of the nature of torrents, being chiefly supplied by the rains which fall in the Apennines. Napoleon remarks, in his 'Military Memoirs,' dictated to Montholon, that an army invading Italy from France finds its march much easier by following the southern instead of the northern bank of the Po.

The Ticino is one of the principal affluents of the Po. It issues out of several small lakes near the summit of the St. Gothard, flows through the Canton Ticino, and enters the Lake Maggiore, out of which it issues again at Sesto, from whence it flows for 60 miles through the great plain, marking the boundary between the Austrian and Sardinian territories. It passes by Pavia and enters the Po a few miles below that city. The Ticino is a very rapid river, but is navigable in the lower part of its course. East of the Ticino the Po receives the Lambro, swelled by the Olona, the river of Milan; and lower down the Adda, a deep and rapid stream, which is the outlet of the Lake of Como, and is swelled by the Brembo and the Serio from the mountains of Bergamo. [Adda.] East of the Adda runs the Oglio or Ollio, a considerable river, which rises in Valcamonica on the borders of the Valtelina, forms the little lake Iseo, and, issuing out of it at Sernico, receives the Mella from Brescia, and the Chiese, which is the outlet of the Lake of Idro, and enters the Po above Borgoforte. The Ollio is navigable by large boats below Pontevico. Its whole course, from its source to its confluence, is about 140 miles. [Brescia, Province of.] Proceeding to the eastward, the next great affluent of the Po is the Mincio, an important river, which is the outlet of the Lake of Garda, and with it forms a geographical division between the Milanese territory, or Lombardy Proper, and the old Venetian territories. The Mincio, after issuing out of the lake at Peschiera, forms the lagoons in the middle of which lies Mantova. Below Mantova it is navigable for large boats down to its confluence with the Po near Governolo.

The Po below Piacenza receives on its southern bank the following rivers, or rather torrents, which rise in the Apennines: 1, the Nura, a small stream; 2, the Taro, a larger river which rises in the mountains of Pontremoli, and after a course of about 65 miles enters the Po above Casal Maggiore; 3, the Parma and Lenza, two small streams in the state of Parma; 4, the Crostolo, a small stream which passes by Guastalla; 5, the Secchia, a considerable river which crosses the duchy of Modena, and enters the Po a few miles below the confluence of the Mincio. The Secchia is navigable for large boats up to Pontebasso near Modena [Modena, Duchy of]; 6, the Panaro, called Scoltenna in the upper part of its course, which rises at the foot of Mount Cimone near the frontiers of Tuscany, crosses the duchy of Modena and part of the papal province of Ferrara, and after a tortuous course of nearly 100 miles enters the Po below Bondeno. The Panaro is navigable for 30 miles above its confluence with the Po. The Panaro is the last affluent of the Po from the south; but on the north bank, below the confluence of the Mincio, various canals, under the names of Canal Bianco, Polesella, Tartaro, Adigetto, &c., bring into the Po part of the waters of the Adige, and the drainage of the marshy country which lies between the two rivers. [Adria.] The Po in former times passed south of Ferrara, but after the dreadful flood of 1152 the main stream changed its bed, and it now passes about three miles north of Ferrara. About twenty miles lower down, near Papozzo, the river divides into two branches; the left or northern one, which is the larger, is called Maestra, or Po Grande, and also Po delle Fornaci; it enters the sea by several mouths, the principal of which, called Maestra, is always navigable by merchant vessels. The length of course from the point of bifurcation to the mouth is about twenty miles. The right or southern branch, called Po d'Ariano, also divides into several mouths, the principal of which is called Po di Goro, and is likewise accessible to merchant vessels from the sea. The tide is only felt in a slight degree about seven or eight miles above the mouths, and it does not rise quite two feet. Small merchant vessels ascend the river as far as Lagoscuro near Ferrara. Higher up the navigation is carried on by boats of the burthen of sixty tons, as far as Cremona in all seasons, and higher up as far as Casale in Piedmont, except in times of great drought. Above Casale the Po is only navigable for small boats or rafts. The whole course of the river, including its windings, is reckoned at about 450 miles.

The width of the bed of the Po, from the confluence of the Ticino to its bifurcation, is from 1200 to 1800 feet. The depth of water varies from 12 to 36 feet. The periodical floods take place in the summer months, in consequence of the melting of the snows in the Alps, but extraordinary floods occur at other seasons also after great rains. From the confluence of the Ticino to its mouth, a distance of about 200 miles, the fall in the bed of the river is about 300 feet of perpendicular height. The Po is not fordable below Turin, and has no bridge across it below that city. The whole course of the Po with its sinuosities is above 400 miles. It is embanked from below Piacenza to the sea, to protect the country from inundations. The Etruscans are said to have first applied themselves to embank the Po. Near Ferrara, and below that town down to the æstuary of the Po, the ordinary level of the water in the river is higher than the country near its banks. (Reina, *L'Origine e Corso del Fiume Po*; Romani, *Dell' Antico Corso del Fiume Po.*) The old bed of the Po, which runs south of the town of Ferrara, and which is still called Po di Ferrara, still receives some of the water of the great river by means of canals, but is chiefly filled by the water of the Reno, a rapid river which rises in the Tuscan Apennines, passes near Bologna, and after a course of above 70 miles joins the Po of Ferrara below that city. The Reno is navigable for boats in the lower part of its course, but only in the winter and spring. The Po of Ferrara divides into two branches: the left or northern is called Po di Volano, from the name of the place where it enters the sea, the right or southern branch, called Po di Primaro, receives several rivers, or rather torrents, from the Tuscan Apennines, namely the Savena, Idice, Silora, Santerno, and Senio. The Po di Primaro enters the sea at Primaro a few miles north of Ravenna. The Lamone, which passes by Faenza, enters the sea by a separate mouth between Primaro and Ravenna. In antient times the Lamone communicated with the Po, and Ravenna itself stood on an island in the delta of that river. (Bertoldi, *Memorie del Po di Primaro*, Ferrara, 1785.) The delta of the Po may now be considered as terminating on the south at Primaro: it extends to the northward as far as the mouth of the Adige at Brondolo near Chioggia, distant from Primaro about 40 miles in a direct line from north to south; unless we consider the mouths of the Brenta and Bacchiglione as forming part of it, as those rivers are connected by canals with the Adige, and the Adige communicates with the Po. In this latter sense the delta of the Po would include all the sea-coast to the northern extremity of the lagoons of Venice, and the river Piave would form the northern boundary of the basin of the Po. The Piave, Livenza, Tagliamento, and Isonzo have each a small separate basin.

The length of the basin of the Po, from the sources of the Dora Riparia at the foot of Mount Genèvre, which is its most western point, to the great æstuary of the Po of Maestra, is 280 miles from west to east. The width of the basin is about 140 miles from the Ligurian and Tuscan Apennines to the Alps of Switzerland and of the Tyrol. The area, if we include in it the whole course of the Adige, is near 40,000 square miles, or about four-fifths of the area of England. The whole of Piedmont in its larger sense, Lombardy Proper, Southern or Italian Tyrol, the western half of the Venetian territory, the Swiss canton of Ticino, some districts of the canton of the Grisons, the duchies of Parma and Piacenza, the papal legations of Bologna, Ferrara, and Ravenna, and that small part of Tuscany which extends along the northern slope of the Apennines and is called Romagna Gran-Ducale—all these countries belong to the basin of the Po. The central part of the basin consists of a wide level plain, about 220 miles long and from 50 to 60 miles wide, the larger part of which lies on the northern side of the course of the river, and between it and the lowest offsets of the Alps. South of the river the hills of Monferrato and the Ligurian Apennines and those of Parma approach near to the bank, and rise rapidly above it, leaving only a small extent of plain between; but farther east, in the country of Modena, Bologna, and Ferrara, the

Apennines of Tuscany make a bend to the southward, leaving a level space of about 30 miles in width between their base and the bank of the Po. The plain or valley of the Po has a general slope from west to east in the direction of the course of the river. On each side of the valley the ground rises towards the Apennines on one side and the Alps on the other, but the slope is more gradual and gentle on the northern side. The town of Como, at the southern extremity of the lake of that name, and at the entrance of the great plain from the north, is 600 feet above the sea; Milan, which is half-way between Como and the Po, is about 400 feet; and Pavia, which is near the banks of the Po, is little more than 300 feet above the sea. The fertility of the plain of the Po is proverbial.

The remainder of the basin of the Po consists of the hilly region and the highlands. The hilly region, which is the most delightful part of the whole, forms a broad belt along the northern border of the great plain, and includes the lakes of Orta, Maggiore, Lugano, Como, Iseo, and Garda. South of the Po are the hills of Monferrato and the lower offsets of the Ligurian Apennines. The highlands are formed by the Alps on one side and the Apennines on the other. [Alps; Apennines.]

POA, the Greek name (πόα) for grass of any kind, is applied by botanists in a more limited sense, being restricted to those plants of the Graminaceous order which have a panicled inflorescence, many flowered spikelets, hermaphrodite normal flowers, a pair of glumes, and paleæ membranous at the point, without being inflated or provided with any kind of armature. Such grasses are abundant in Europe, the most common of all flowering plants being Poa annua, the little annual grass which springs up everywhere in the absence of the gardener, flowering and ripening its seed at all seasons when not actually frozen. It is probable that the perennial species are mostly suited for agricultural purposes, because they are destitute of the stiff hairs which render many grasses unpalatable to cattle. It is only the strongest growing kinds however that produce sufficient fodder to be profitable to the farmer, and among them the *Poa trivialis* and *pratensis*, two meadow species, are the most valuable.

POACHING. [Game Laws.]

POCILLO'PORA. [Madreporæa.]

POCKLINGTON. [Yorkshire.]

POCOCK, EDWARD, an eminent divine and learned Orientalist, was the son of the Rev. Edward Pocock, vicar of Chiveley in Berkshire. He was born at Oxford, in November, 1604, and received the early part of his education at the free-school of Thame. At the age of fourteen he was entered a commoner of Magdalen Hall. After two years' residence there, he was elected to a scholarship of Corpus Christi College, to which he removed in 1620. In November, 1622, he was admitted bachelor of arts. He now began to apply himself to the study of the Oriental languages, in which he made extraordinary progress, first under the tuition of Matthew Pasor, and afterwards under that of the Rev. William Bedwell, vicar of Tottenham, one of the first of those who have promoted the study of the Arabic language in Europe.

His first literary work was the preparation for the press of such parts as had not been edited of the Syriac New Testament, from a manuscript in the Bodleian library, to which he added a Latin translation and some notes: the whole was printed at Leyden in 1630, 4to. In 1629 Pocock was ordained priest, and soon after appointed chaplain to the English merchants at Aleppo, where he continued five or six years, making further progress in the Hebrew, Syriac, and Ethiopic languages, besides acquiring a familiar knowledge of the Arabic. On his return to England in 1636, he was admitted to the degree of bachelor of divinity, and soon after nominated first Professor of the Arabic lecture founded at Oxford by Archbishop Laud, with whom Pocock had maintained a correspondence during his stay at Aleppo, having been employed by that liberal prelate in collecting coins and MSS. for the university. He opened his lectures with an elegant Latin oration on the nature and utility of the Arabic tongue, part of which was afterwards published *ad calcem* 'Carmen Tograi,' edit. Oxon., 1661. Pocock however seems not to have delivered more than one course of lectures upon this occasion; for soon after, at the express desire of his patron Laud, he undertook a second voyage to the East, along with John Greaves [Greaves], and remained some time at Constantinople collecting antient manuscripts. After a stay of nearly four years in that city, he embarked in 1640, and returned home by way of France and Italy. While at Paris he became acquainted with many of the learned men of the time, and particularly with Gabriel Sionita, a Maronite well known by his Latin translation of Edrisi's 'Geography,' and other works [Edrisi], and with Hugo Grotius, to whom he communicated a design he had of translating his treatise 'De Veritate' into Arabic for the use of the Mohammedans. Grotius having approved of the plan, Pocock began his task, and the Arabic version was afterwards printed at Oxford, in 1660. [Grotius.] While at Paris, Pocock heard of the commotions in England, and on his arrival found his patron and benefactor, bishop Laud, a prisoner in the Tower. [Laud.] He now resumed his lectures and his private studies at Oxford. Having become acquainted with the celebrated Selden, who afterwards published part of the 'Annals' of Eutychius, in Latin and Arabic, under the title of 'Origines Alexandrinæ,' Pocock assisted him in collating and extracting passages from the Arabic MSS. in the Bodleian.

In 1643 Pocock was presented by his college to the rectory of Childrey in Berkshire, where he performed with the greatest zeal his duties of parish priest, visiting Oxford during term time. Immediately after the execution of Laud, the profits of his Arabic professorship were seized as part of that prelate's property, and he was reduced to his country living. In 1646 Pocock married the daughter of Thomas Burdett, Esq., of Hampshire, and in the following year he obtained, through the interest of his friend Selden, the restitution of his salary. In 1648 he was nominated to the Hebrew professorship at Oxford, to which Charles I., then a prisoner in the Isle of Wight, added a canonry in Christ Church, which was confirmed by parliament; but the canonry thus assigned to him being different from that originally annexed to the professorship, Pocock entered a protest against it, and refused to receive the profits. In the mean time he composed his 'Specimen Historiæ Arabum,' being extracts from the work of Abu-l-faraj, in the original Arabic, together with a Latin translation and copious notes. [Abulfaragius.] This work, which was printed at Oxford, in 1648 and 1650, 4to., was reprinted in 1806, by White, with some additions by Sylvestre de Sacy. In November, 1650, about a year after publishing the preceding work, Pocock was ejected from his canonry, and it was intended to deprive him of the Hebrew and Arabic professorships; but upon a petition from the heads of houses, the masters, and scholars at Oxford, Pocock was suffered to enjoy both places. In 1655 he was on the point of being deprived of his living, on the ground of 'ignorance and insufficiency;' at least such were the charges preferred against him by Cromwell's committee. Some of his Oxford friends however, particularly Dr. Owen, so warmly represented the disgrace which would follow the rejection, upon such grounds, of so eminent a scholar as Pocock, that the measure was abandoned. Soon after Pocock published his 'Porta Mosis,' being six prefatory discourses of Moses Maimonides's 'Commentary upon the Mishna,' written in Arabic, but with the Hebrew letters. This work, which was the first production of the Hebrew press at Oxford, appeared in 1655 (not 45, as printed by mistake in the article Maimonides), together with a Latin translation and numerous notes. In the following year Pocock appears to have entertained the idea of publishing the 'Expositions of Rabbi Tanchum on the Old Testament,' as he was at that time the only person in Europe who possessed any of the manuscripts of that learned Rabbi; but, probably from want of encouragement, he did not prosecute his design. In 1657 the English Polyglot appeared, in which Pocock had a considerable hand. He collated the Arabic Pentateuch, and also wrote a preface concerning the different Arabic versions of that part of the Bible, and the reason of the various readings to be found in them, the whole of which was inserted in the Appendix to the Polyglot. He also contributed greatly to the success of that literary undertaking by the loan of several valuable MSS. in his own collection. In 1658 his Latin translation of the 'Annals' of Eutychius was published at Oxford, in 2 vols. 4to., at the request and at the expense of Selden, who died before it appeared. At the Restoration, Pocock was restored (June, 1660) to his canonry of Christ Church, as originally annexed to the Hebrew professorship by Charles I. In the same year he was enabled, through the liberality of Mr. Boyle, to print his Arabic translation of Grotius's tract 'De Veritate.' His next publication, in 1661, was the Arabic poem by Abú Ismail Thograí, entitled 'Lámiyyatu-l-'ajem,' with a Latin translation, copious notes, and a learned preface by Dr. Samuel Clarke. But by far the most important as well as the most useful of Pocock's works was his translation of the entire work of Abu-l-faraj, which, along with the text and a few excellent notes, was printed at Oxford, in 1663, 2 vols. 4to. After the publication of this work he seems to have entirely devoted himself to biblical learning. In 1674 he published, at the expense of the university, his Arabic translation of the Church Catechism and the English Liturgy. In 1677 appeared his 'Commentary on the Prophecies of Micha and Malachi;' in 1685, that on Hosea, and in 1691, that of Joel. It was his intention to comment upon others of the lesser prophets. He died, September 10, 1691, after a gradual decay of his constitution, in the eighty-seventh year of his age.

Pocock had by his marriage with Miss Burdett nine children, the eldest of whom, named Edward, was also an Oriental scholar, and published in 1671, under his direction, the philosophical treatise of Ibn Tofayl, with a Latin translation and notes, under this title—'Philosophus Autodidactus, sive Epistola Abu Jaafar Ebn Tophail de Hai Ebn Yokdham,' the same which Ockley afterwards translated into English. [OCKLEY.] He also translated into Latin the work of Abda-l-latif on Egypt; but it was not printed until the beginning of the present century, when White published it with the original text, Oxford, 1800, 4to. [ABDALLATIF.] Another of Pocock's sons, named Thomas, translated into English the work entitled 'De Termino Vitæ' by Manasses Ben Israel, under this title — 'Of the Term of Life,' London, 1699, 12mo. An account of the life and writings of Pocock, the father, was published in 1740, by Leonard Twells, M.A., together with an edition of his Theological works, in 2 vols. folio.

POCOCKE, RICHARD, a distinguished traveller, distantly related to the preceding, though he added an *e* to his name, was born in 1704, at Southampton, where he was educated until he removed to Corpus Christi College in Oxford. In 1731 he took the degree of bachelor of laws, and two years afterwards that of Doctor. After travelling in the years 1734 and 1736 on the Continent, he sailed for Egypt, in which country he remained until the spring of 1738, when he embarked at Damietta for Palestine, and taking his road through Syria, Mesopotamia, Cyprus, Candia, and Asia Minor, arrived at Constantinople. From Cephalonia he sailed to Messina, whence he proceeded homewards through Italy, Germany, and Flanders. On his return in 1741 he published the result of his researches and observations, under the title of 'Description of the East and of some other Countries,' of which the first volume, entitled 'Observations on Egypt,' dedicated to Henry, Earl of Pembroke and Montgomery, appeared at London in 1743, folio; and the second, entitled 'Observations on Palestine, Syria, Mesopotamia, Cyprus, and Candia,' dedicated to Philip, Earl of Chesterfield, in 1745. In 1745 he was appointed archdeacon of Dublin, and in 1756 bishop of Ossory. He was subsequently transferred to Elphin, and lastly to Meath, where he died, in September, 1765.

Besides his 'Eastern Travels,' which are works of merit, Pococke made a tour in Scotland and published a description of the basaltic rock, in the harbour of Dunbar, resembling the Giant's Causeway. (*Phil. Trans.*, vol. 32, art. 17.) 'A Description of the Giant's Causeway,' and 'An Account of some Antiquities found in Ireland,' were also published by him in the 11th vol. of the 'Archæologia.' Among the MSS. in the British Museum (4811, 4827) are several volumes the gift of Bishop Pococke, containing the minutes and registers of the Philosophical Society of Dublin, from 1683 to 1707. A French translation of his travels appeared at Paris, in 1771, in seven volumes, in 12mo.

PODA'RCIS, Wagler's name for a genus of Lizards, part of which genus is placed, by MM. Duméril and Bibron, under the genus *Lacerta*, part under the genus *Acanthodactylus* of Fitzinger, and part under the genus *Eremias* of the last-named herpetologist.

PODARGUS. (Zoology.) [NIGHT-JARS, vol. ,xvi., p. 225.]

PODESTA. [LOMBARDY.]

PO'DICEPS. [DIVERS, vol. ix., p. 36.]

PODICEPSI'NÆ, Mr. G. R. Gray's second subfamily of the *Colymbidæ*. [DIVERS.] The first subfamily is *Colymbinæ*, consisting of the single genus *Colymbus*, Linn. (*Mergus*, Briss.; *Urinator*, Lacép.; *Eudytes*, Ill.).

The *Podicepsinæ* consist of two genera: 1, *Podiceps*, Lath. (*Colymbus*, Briss.); 2, *Sylbeocyclus*, Bonap. (*Colymbus*, Linn.; *Podiceps*, Ray; *Podilymbus*, Less.; *Dasyptilus*, Sw.).

PODILYMBUS. [PODICEPSINÆ.]

PODINE'MA, Wagler's name for a genus of *Monitory Lizards*, arranged by MM. Duméril and Bibron under their genus *Salvator*. [SALVATOR.]

PODLACHIA. [POLAND.]

PO'DOA, Illiger's name for a genus of Natatorial or Palmipede birds, *Heliornis* of Bonnaterre, *Grébifoulques* of Buffon. These have their feet lobated, like the *Foulques* (*Fulicæ*) and the *Grebes*, but their tail is more developed than in either, and their nails are sharper. Cuvier cites *Plotus Surinamensis*, Gmel., *Enl.*, 893; *Heliornis Senegalensis*, Vieill, *Gal.*, 280, as examples, and observes that M. Ch. Bonaparte (Prince of Musignano) considers, like Gmelin, that the genus should be approximated to the *Anhingas*. [PELECANIDÆ.]

PODOLIA, or KAMENETZ-PODOLSK, a government of European Russia, formerly a part of Poland, extends from 47° 25′ to 49° 45′ N. lat., and from 26° 20′ to 28° 50′ E. long. It is bounded on the north by Volhynia, on the north-east by Kiew, on the east and south-east by Kherson, on the south by Bessarabia, from which it is separated by the Dniester, and on the south and south-west by Austrian Galicia. The area is very differently stated by different writers. Hassel (in 1821) and Schubert (1835) make it 19,850 square miles; but Schmidtlin (1835) prefers the estimate of Marczynski, who makes it only 14,500 square miles. Podolia is generally a table-land of no great elevation, and is traversed by a branch of the Carpathians, which enters it from Galicia; but the most elevated parts of this chain are scarcely 500 feet above the level of the sea, and only heighten the picturesque beauties of this fine province. The south-eastern parts, which formerly belonged to the Ukraine, are sandy, and form a kind of steppe. The province is well watered. The Dniester, which is the principal river, flows indeed only along the frontier towards Bessarabia, but most of the small rivers run into it. The second principal river is the Bug. The Dniester is broad, but its course is rapid, and the navigation is rendered dangerous and difficult by numerous shallows, rocks, blocks of stone, and whirlpools. The same may be said of the Bug, which is obstructed by large blocks of stone, which however might easily be removed. There are numerous small meres in the western part of the province, but no large lakes.

The climate is mild and in general very healthy; there are scarcely any endemic disorders, except the Plica Polonica, which will probably remain endemic as long as the uncleanliness of the Russniaks and Poles continues. The soil of Podolia is proverbially fruitful, 'yielding a return,' says Hassel, 'which is scarcely equalled in Sicily. Wheat and rye often produce tenfold, and many kinds of grain 20, 50, and even 100 fold.' Schmidtlin however says 'the soil is extremely productive, but without yielding tenfold, as Hassel says, who uniformly exaggerates in this particular.' Besides all kinds of corn, hemp, flax, tobacco, and hops are cultivated. Agriculture is however practised in the most slovenly manner; the ground is scarcely scratched by the plough, it is never manured, and the same species of grain is often sown for several years together. Yet corn is so abundant, and of so little value, that, for want of demand, it has been often left to rot on the ground. The increasing exportation from Odessa has however caused a considerable improvement. The peasants have generally gardens, where they cultivate cabbages, onions, cucumbers, water-melons, and some fruit-trees, mostly apples, pears, cherries, and plumbs, but no great care is bestowed on them. The grass is remarkably luxuriant, and the forests are very extensive, but there is not much game in them; stags and deer are rare; in the fields and in the steppe between the Bug and the Dniester there are hares, wolves, foxes, a species of antelope, and bustards. Storks are very numerous. Swarms of locusts come periodically from the Black Sea. The breeding of cattle is very important; the oxen of Podolia are remarkably large and fine, and great droves of them are annually sent even to the middle of Germany. The race of horses is much esteemed. The sheep are of a good breed, and their wool is tolerably fine. Swine are very numerous. The farmers breed great quantities of domestic poultry and of bees. The fisheries are very productive. There is no metal except bog-iron. The other mineral products are saltpetre, stone for building, lime, gypsum, and alabaster. The manufactures are of very little importance, and not sufficient even for the supply of the inhabitants. There is hardly any wholesale trade in the province. What the farmer has to spare, such as corn, flour, hemp, flax, tobacco, timber, potashes, pitch, oxen, horses, tallow, wax, honey, &c., he sells to the Jews, who take the corn to Odessa, the oxen to Brody and Germany, and carry on a profitable contraband trade with Austria and Moldavia. Almost all the brandy distilleries, which are considerable, are in the hands of the Jews. Education is very limited. The schools are few in number, and Schmidtlin says he could not ascertain the number of scholars in the Roman Catholic, Greek, Jewish, Armenian, and other schools, and that there was but one printing-office (that of the government) in all Podolia. The greater part of the inhabitants are of the Greek religion. The Roman Catholics are numerous, as are also the Jews. There are some colonists, and some Greek and Armenian merchants. There are also a few gypsies. The population of this province has been variously stated, but it is probable that it amounts to at least 1,500,000.

The principal town is Kaminiec, the capital of the province, on the river Smotriza, at a short distance from its junction with the Dniester. It was formerly the most important fortress in Poland, but is now deprived of its fortifications; it consists of the upper town, of the lower, which is well built, and several suburbs. It has a very fine cathedral, a gymnasium, some manufactories and trade, and 16,000 inhabitants, half of whom are Jews. The other principal towns are the capitals of the circles (12 in all), but none of these are of great importance. Mohilew alone has 7000 inhabitants, a silk manufactory, and some trade. (Hassel; Cannabich; Schubert; Schmidtlin.)

PODOPHTHALMA, PODOPHTHALMIANS. Dr. Leach divided his *Podophthalma* into the two orders of *Brachyurous* and *Macrurous Crustaceans.* Latreille and Desmarest make the first order of the *Podophthalma*, the *Decapoda*, and the *Brachyura* and *Macrura* (*Brachyuri* and *Macrouri* of Latreille) families. M. Desmarest thus defines the *Podophthalma*:—

Composite eyes placed at the end of a moveable peduncle; no simple eyes; mandibles provided with a palp; jaw-feet always having a palp adhering to their base.

M. Milne Edwards makes the Podophthalmians the first legion of the subclass of *Maxillated Crustaceans*, and observes that the Crustaceans of which this grand division is composed present such multiplied analogies to each other, that it is impossible to refuse to unite them in the same group. This division, continues M. Milne Edwards, corresponds very nearly to Lamarck's order of *Crustacés Pédiocles* and to Dr. Leach's *Malacostraca Podophthalma;* but, in the opinion of M. Milne Edwards, it reposes on different bases, and can no longer preserve the limits assigned to it by those authors. We now proceed to lay before our readers the views of the last-named distinguished zoologist as to this great group.

M. Milne Edwards then observes, that the most remarkable trait of the organization of *Podophthalmians* consists in the disposition of the respiratory apparatus. In the other crustaceans it is the general envelope of the body or a portion of the thoracic or abdominal members which serves for respiration; but in the *Podophthalmians* this important function is nearly always entrusted to special organs which are not simple modifications of any of the ordinary appendages of the members. The existence of *branchiæ properly so called* is one of the most important characters of this natural group; but in some of the last Podophthalmians these organs become rudimentary, nay, even disappear completely, and are replaced by the general tegumentary envelope, as in the genera *Cynthia, Mysis*, and *Phyllosoma.* On the other hand, there are crustaceans which are provided with analogous organs, but which evidently do not belong to this tribe. Thus the females of *Jone* [ISOPODA] carry well-developed branchiæ fixed to the abdominal members: they are the only crustaceans actually known which, without belonging to the natural group of Podophthalmians, are provided with true branchiæ; and yet these organs do not exist in both sexes; the males have them not.

Another character, which is not wanting in any Podophthalmian, but which does not possess the same physiological importance, is furnished by the ophthalmic ring of the head, which is always provided with a pair of moveable members, at the extremity of which are found the eyes. But these are not the only crustaceans which have pedunculated and moveable eyes; the *Nebaliæ*, which undoubtedly belong to another group, are equally provided with them.

The buccal apparatus of the Podophthalmians is disposed for mastication, and is always composed of a labrum but little developed, of a pair of mandibles, and of one pair at least of jaws. The second pair of jaws enter also into the composition of the masticatory apparatus, and it is nearly the same with regard to the post-buccal members of the fourth pair; but these organs are never enlarged and united so as to constitute a kind of lower lip or buccal operculum, as it is seen in the *Edriophthalmians.* Finally, in the greater number of cases the two succeeding pairs of members are equally transformed into jaw-feet, and sometimes the number of these organs is even more considerable, for in certain species (the *Squillæ*, for example) all the thoracic members, with the exception of the last three pairs, may be regarded as such.

The thoracic members destined for locomotion are nearly always five or six pairs; their stem is always vergiform, and constitutes a slender foot, which is elongated and ordinarily ambulatory, sometimes carrying at the same time a *flagrum*, or else a palp, but hardly ever presenting at the same time two kinds of appendages. This mode of conformation of the locomotive organs clearly separates the Podophthalmians from all the crustaceans whose thoracic feet are lamellar, as the *Nebaliæ*, above alluded to, but is found in many other divisions of the class.

Finally, the animals of this legion may be distinguished at the first glance from all the other crustaceans by the existence of the great cephalic buckler which occupies the dorsal surface of the body, and extends more or less far below the thorax. Certain *Branchiopods* have also a similar carapace, but they then differ from the Podophthalmians by some of the characters of still greater importance already pointed out.

If the whole of their organization be taken as the basis of the classification of the *Crustacea*, as M. Milne Edwards states that he has attempted to do, the legion of Podophthalmians ought to be thus characterised:—

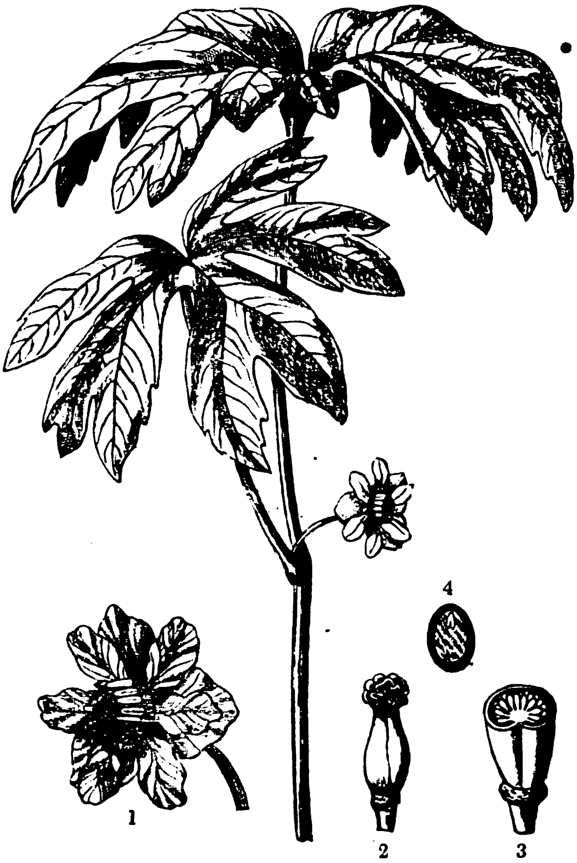
Mouth armed with mandibles and jaws proper for mastication; in general *branchiæ* properly so called; *eyes* pedunculated and moveable; thoracic *feet* vergiform; a *carapace.*

According to the system of M. Milne Edwards, the *Podophthalmians* form two orders, the *Decapods* and *Stomapods.* This division, he observes, is generally adopted, but the greater number of authors establish it on the number of thoracic members which constitute the locomotive apparatus; whilst, according to his rule, it is in the disposition of the respiratory apparatus that we ought to look for the principal bases. (*Histoire Naturelle des Crustacés.*)

PODOPHTHA'LMUS. [PORTUNIDÆ.]

PO'DOPHIS, Wiegmann's name for a genus of *Scincoidean Lizards*, belonging to the subdivision which have not the auditory apertures visible.

PODOPHY'LLEÆ, a small group of polypetalous Exogens, by some regarded as a distinct natural order, and by others referred to Ranunculaceæ as a section. They would be Papaveraceous plants if they had consolidated carpels; but possessing no more than one carpel, they appear more referrible to Ranunculaceæ, from which, in fact, they seem only to differ in having a solitary carpel, which however also occurs in that order, although not characteristic of it. The only species referred to Podophylleæ are Jeffersonia and Podophyllum, two North American plants, with succulent acrid root-stocks, deeply lobed leaves, and white flowers hidden among them. They have three or four sepals, twice as many petals, indefinite hypogynous stamens with linear or oval anthers, a thick sinuous stigma, and the ovules arranged along the central suture of the solitary carpel. Podophyllum peltatum, or May-apple, is not uncommon in gardens, whither it has been introduced from the United States, where it is employed as a safe and active cathartic.



Podophyllum peltatum.

1, a flower; 2, a carpel; 3, a transverse section of the same; 4, a vertical section of a seed.

PODOPSIS. [SPONDYLIDÆ.]

PODOSTEMMA'CEÆ, an obscure natural order of tropical submersed aquatic plants, with minute incomplete flowers. They appear to have no very obvious relation to any other natural group, and are little known even to botanists except by name. They however are certainly Exogens, and probably allied to Urticaceæ and Piperaceæ. Endlicher places them among his aquatic class, consisting of Ceratophylleæ, Callitrichineæ, and Podostemmeæ, and enumerates seven genera.

PŒCILONITTA, Mr. Eyton's name for a genus of Ducks (*Mareca*, Steph.; *Anas*, Linn.).

Example, *Pæcilonitta Bahamensis*.

PŒCILO'PODA, M. Latreille's name for his sixth order of Crustacea, and arranged by him under his second subclass, *Entomostraca*.

The following is M. Desmarest's character of the order:—

Head confounded with the trunk; a shell, or the anterior of the body in the form of a buckler; mouth in the shape of a beak, or composed of appendages which cannot be compared to mandibles; antennæ short and simple or null; often eyes distinct and sessile; anterior feet terminated by one or two hooks or by claws, fit either for walking or prehension; the posterior feet destined for natation, either composed of or accompanied by branchial laminæ, or membranous and digitated.

1st Division.

Mouth in form of a beak; antennæ to the number of four; twelve feet, of which the first two are in the form of acetabula, or suckers (ventouses). Family *Argulidæ*, Leach.

Argulus is the only genus of this division.

2nd Division.

Mouth in form of a beak; antennæ to the number of two only. Family *Caligidæ*, Leach.

These, says M. Desmarest, like the last, are crustaceous aquatic parasites: the greater part of them are marine, adhering to the branchiæ and the axillæ of fishes, having the antennæ inserted at the external angle of two lobes on the anterior surface of their shell, and the eyes most frequently not apparent.

1st Subdivision or Race.

Twelve feet; the six anterior terminated by hooks or unguiculated. Extremity of the abdomen furnished with two bristle-like appendages or oviferous tubes, which are cylindrical and elongated.

The genera arranged by M. Desmarest under this subdivision are *Anthosoma*, Leach (*Caligus*, Latr., Lam., Risso), and *Dichelestium* of Hermann the younger and authors.

2nd Subdivision or Race.

Fourteen feet; the six anterior unguiculated; the fourth or fifth pair bifid; the sixth and seventh having the haunches and the thighs very much dilated and united by pairs.

Cecrops, Leach, is the only genus placed by M. Desmarest under this subdivision.

3rd Subdivision or Race.

Fourteen feet; the six anterior unguiculated; all the others bifid.

The genera arranged under this subdivision are *Pandarus*, Leach (*Caligus*, Latr. and Lam.), and *Nogaus*, Leach.

4th Subdivision or Race.

Fourteen feet; the six anterior unguiculated; the fifth pair bifid, with the last joints ciliated with hairs.

Caligus, Müller [CALIGUS], and *Risculus*, Leach, are the genera arranged under this subdivision.

3rd Division.

Mouth with its aperture in the middle of five pairs of feet or jaw-feet, terminated in pincers, the haunches of which, rough with points, may serve for mastication; no antennæ; shell in the form of a buckler, consisting of two pieces, and terminated by a long sword-shaped tail; organs of respiration placed under the second piece of the shell. Family *Limulidæ*, Leach.

The genus *Limulus* (*Limulus*, Müll., Fabr., Lat., Leach; *Monoculus*, Linn.; *Xiphosura* and *Xiphotheca*, Gronov.; *Polyphemus*, Lam.; *Cancer*, Clus.) is the only one belonging to this division. [XIPHOSURIANS.]

See further SUCTORIAL CRUSTACEANS.

POELEMBURG, CORNELIUS, was born at Utrecht, in 1586, and studied painting under Abraham Bloemart. Having acquired considerable proficiency under him, he went to Rome, where the works of Raphael inspired him with a resolution to endeavour to imitate the grace of that great master, especially in the naked figure. But though he doubtless derived much advantage from the study of Raphael, he formed for himself a very different and entirely new style, not resembling that of any Italian master, unless it be in his adorning his landscapes with the ruins of antient buildings, which he designed with great accuracy after nature. He excelled all his contemporaries in the delicacy of his taste and the vividness of his colouring, as well as in the choice of his subject. The skies are clear, light, and transparent, and the magnificent remains of Roman edifices in his backgrounds give harmony to the whole composition. His female figures, which he generally represented naked, are distinguished by beauty and elegance of form. It has been objected that in some representations of nymphs bathing, he has chosen exposed situations by a roadside.

Poelemburg's works were highly esteemed in Italy, and some of the cardinals used to visit him while he was painting, to observe his manner of working. He left Rome with much regret, and returned to his own country. On the way he received many honours, at Florence from the grand-duke, and had great respect shown him in all the cities through which he passed, as well as in his native city of Utrecht. Soon after his return he was visited by Rubens, who expressed great pleasure in examining his works, of which he purchased several for his own collection, and bespoke others, by which he directed attention to the merit of Poelemburg, and advanced both his fortune and his reputation.

Poelemburg was invited by Charles I. to London, where he painted many fine pictures, for which he received large sums. The king wished him to stay in England; but his affection for his own country induced him to return to Utrecht, where he acquired a large fortune and was universally esteemed. Many eminent artists, especially Steenwyck and Kierings, got him to paint the figures in their works. The genuine pictures of Poelemburg are extremely scarce, but his disciple, Jean van der Lis, imitated his manner with such success that his paintings are often taken for works of his master. Dr. Waagen mentions the following works of Poelemburg in English collections:—at Corsham-house, the seat of lord Methuen, two landscapes with nymphs (to the most delicate touch is added extraordinary force and depth of tone); at Mr. Beckford's at Bath, a Repose in Egypt (a capital picture, of a larger size than usual with him, yet with all the delicacy of his smaller pictures), and very pretty little pictures with nymphs; at Burleigh-house, Christ and his two Disciples on the way to Emmaus (the usual delicacy of execution is here united with uncommon force); at Luton-house, a Repose in Egypt, of most delicately pure execution and soft warm harmony.

POETRY, in the usual and proper signification of the word, is applied to any composition in metre. It designates the outward form, not the style or the subject-matter treated. As however there are certain subjects, certain feelings and language, which belong to good poetry, a prose composition, in which these characteristics are visible, is often termed 'poetical' or 'poetry,' just as a bad poem is called 'prosaic.' In both instances we speak thus when we wish to express praise or blame, as the case may be, and we use the words metaphorically. (See Whately's *Rhetoric*, page 278.)

The art of poetry is an imitative art. Its object, in common with all such arts, is to give pleasure by imitation. So far music, painting, sculpture, and poetry agree; they differ in the means which each employs to effect the imitation. Music works by harmony and melody, painting by colour, sculpture by form, and poetry by words arranged in metre. In no case however is it the proper province of art to produce illusion, that is to say, the person whose feelings are to be affected always remains conscious that his emotion is not the result of anything really passing, but is merely analogous to that emotion which the reality would produce.

The imitative power of art thus consists in producing results resembling, but not identical with, those created by natural objects, or by human passion, character, and action. Hence the difference between a diorama and a picture, or between a waxwork figure and a statue: illusion is the aim of the one; imitation, properly so called, of the other. Hence too it is difficult to vindicate the mimicry of special sounds, such as hail or thunder, in music.

The metre in poetry answers a double purpose: in itself it affords pleasure by its rhythm, and acts as a powerful auxiliary to the sense which the mere words express; but above all, it preserves the essence of art by operating as a constant barrier against any approach to reality. In this way the poet avows the fact that his work is a work of art, and he makes the reader or hearer aware of the relation in which he and the author stand to each other. The imitative power may work in safety when hedged off from real life by the fence of metrical form, and thus it is that Wordsworth lays down the 'perception of similitude in dissimilitude' as one of the principles on which verse gives pleasure.

The next question is, in what mode does poetry imitate? Painting and sculpture copy outward forms themselves; poetry and music, being restricted to instruments of a different kind, aim at imitating the effect of those forms, that is to say, at producing the pleasurable emotion in the reader or the hearer, though in these cases they cannot imitate the means. On the other hand, the two former arts can only represent one moment of action or expression, and must tell their story by selecting that moment properly; music and poetry can supply a succession of images and sentiments all going to make up a whole. There is one advantage which poetry possesses over all its sister arts, viz. that of being able to assert: as it is the only art which employs words for its instruments, it is the only one which can enounce a proposition and command this element of the moral sublime.

Poetry, ποίησις, or 'making,' seems to be so called because good poetry creates or re-embodies the impressions which the poet has imbibed into his own mind by observation. This faculty of producing from such elements the impression of individual character, action, or scenery, is the power which we generally term imagination. Without it the attempt at imitation must necessarily fail. Wordsworth (Preface to 'Lyrical Ballads') says, 'Poetry is the spontaneous overflow of powerful feelings; it takes its origin from emotion recollected in tranquillity. The emotion is contemplated until by a species of reaction the tranquillity gradually disappears, and an emotion kindred to that which was before the subject of contemplation is gradually produced, and does itself actually exist in the mind.' This we take to be a description of the mode in which imagination works. The poet, by close and habitual observation, stores his mind with the circumstances which have given rise to or attended the production of emotion in himself. The result of this observation he works up so as to create in others an emotion kindred to that which he has himself experienced; kindred, but not identical, for, as Wordsworth truly remarks, the excitement must co-exist with an overbalance of pleasure. Now many of the emotions which the poet excites are, when called forth by real events, peculiarly painful. It is his business so to combine them with pleasing associations, so to soften their disgusting features and render prominent their more attractive ones, and above all so to give unity to the whole, that, taken with the consciousness of their existing in a work of art, and not in reality, they become a source of exquisite delight. Such a work is reality seen through the medium of the poet's mind, and clothed by him in a bodily form so as to retain its vividness, but lose its deformity.

It has been often observed that the language of savages is highly metaphorical and what is commonly called poetical; that nations in their earlier stage show a peculiar fondness and aptitude for poetry. The truth is that there exists in the mind of man a natural craving for individuality. We gain knowledge by generalising from individual objects, and we are always eager to re-embody our abstractions. Even in the most civilised state, there is a perpetual tendency in the mass of mankind towards 'realism,' while the consistent and familiar use of abstract terms and symbols implies long and severe discipline of the reasoning powers. These feelings are the groundwork of all allegory. If we reflect a moment, we know that 'justice' means that disposition of mind which we see exhibited by individuals who are called 'just,' yet we speak of her as if she were a real existing being, and paint her with a pair of scales and a sword. Thus the appetite for the imitative arts is one deeply implanted in man; he cannot be satisfied unless character or action lie embodied to the eye by colour and form, or brought vividly before the mind by the description of the poet. Abstract terms are indistinct, and require metaphors or similes to give them substance and make them palpable to the apprehension. One of the most wonderful phenomena connected with the Greeks is, that while the genius of the people constantly tended, as Mr. Thirlwall says, to embody the spiritual and personify the indefinite, they excelled no less in the dry and abstract studies of philosophy. If Homer, if Æschylus and Sophocles, have never been rivalled in poetry, it was Aristotle on the other hand who analysed with the greatest precision the process of human reasoning, and left us in his 'Ethics' and his 'Politics' treatises which are still instructive in their respective departments.

We must now proceed to say something of the diction of poetry. Words are the instruments of the poet; they are the tools with which he works. We think that Mr. Wordsworth pushes his theory of simple language a little too far. We fully sympathise with his rejection of 'those phrases and figures of speech which from father to son have long been regarded as the common inheritance of poets.' Such conventional forms of expression at last become adverse to the very object of all poetry; instead of conveying any definite or substantial image, they degenerate into mere formulæ of the vaguest and most unsatisfactory kind. But just as metre at once gives pleasure by its adaptation to the subject-matter, and forms a sort of framework in which the poet exhibits his composition to the reader, so may language, by its appropriateness and by its dissimilitude to the phraseology of common life, supply another twofold source of pleasure. There are ballads, and even larger compositions, in which the simple and homely diction suits the treatment of the subject and adds force and strength to the expression. But who will say that in such a work as the 'Agamemnon' of Æschylus, where the whole drama is knit together by one pervading feeling of mysterious dignity, the language should not bear a proportion to the other qualities of the work?

'Let gorgeous tragedy
In sceptered pall come sweeping by:'

stately and ornate diction is a part of her trappings.

We must next, as far as our limits will permit, consider the different moulds into which a subject may be cast by a poet, and according to which we call a poem epic, dramatic, lyric, &c. There is great difficulty in this part of our sub ject. The antients indeed applied such terms as 'epos' or 'elegeion' to the outward form only, but in modern language the matter of a poem, its length, or its mode of treatment, often decides the class to which it is commonly assigned. Moreover there are many works of a mixed character which we cannot place in any recognised division. To what genus do Dante's 'Divina Commedia,' Wordsworth's 'Excursion,' and Spenser's 'Fairy Queen' respectively belong? Certain broad distinctions may however be laid down, though they be incapable of definite application in every instance.

1. A poem may be in the form of a narrative of events which the poet professes to recount; although he sometimes introduces his heroes as speaking in the first person, and uses the historical present tense for the sake of greater energy, still the events are supposed to be *past*. The subject-matter is external, that is to say, the writer does not merely pour forth his own feelings as excited by certain actions or circumstances, but describes the actions or circumstances themselves. Of this kind is all epic and narrative poetry.

2. A poet may develop the action to the reader or supposed spectator by imagining that the personages of the story show its progress and their own characters by what they themselves say and do, not by what the author narrates of them. Here the time is supposed to be present, and the subject-matter still more purely external. Dramatic poetry, with all its numerous subdivisions, is of this kind.

3. The author may principally aim at expressing the overflow of his own emotions and his own sentiments, instead of narrating what is past or supposing something present to be acted before us. His object will then be to awaken an echo of similar feelings in the reader or hearer, and thus *imitate* the action of those impulses which have previously excited such feelings in his own mind. Most short compositions intended to be sung belong to this class. If the tone of thought is enthusiastic and the metre irregular, we call the work an ode; if it express tender or mournful feelings in a more regular form, it is an elegy; the name 'sonnet' marks the outward form only. Perhaps no general word can be found so applicable to the greater part of those compositions which are neither epic nor dramatic as the term 'lyrical,' though it does not seem in any usual sense to include epigram, satire, or didactic poems.

1. Epic poetry. It is a most curious fact in the history of human culture, that the earliest existing epic poem should be still unquestionably the finest. In the mechanical arts each generation profits by the diligence of its forerunners, and builds on the foundation which it finds existing. Whatever has been achieved accumulates for the benefit of posterity. In the imaginative arts the case is wholly different: the sudden exuberance and sudden decay of excellence are equally unaccountable. Whether composed by one or by many individuals, the works which bear the name of Homer undoubtedly possess a certain unity of action, and are just as admirable for the touches of pathos and gentler feeling which they contain, as for the vigour and life which we might imagine likely to characterise the early period to which they belong. Speaking a dialect equally expressive in energy and softness, the Greek epic causes its narrative to dwell on every part of the subject more equally than is consistent with the condensed form and single crisis of the drama. Whether in the combat, the feast, or the sacrifice, Homer's heroes and the actions in which they are engaged pass before us in tranquil succession, like the figures on a bas-relief; while a tragedy of Sophocles may be said to stand out by itself with concentrated interest and sharply defined outline, like the Laocoon or any single group of sculpture. The verse too is admirably adapted to this spirit. The hexameters, unrestricted by any pauses at fixed intervals, and thus free from the point or sententiousness of the later elegiac metre, flow on in an unbroken stream, accommodating themselves to the tone of thought and the subject-matter. At the same time they are less colloquial than the trimeter iambic of the drama.

To Homer succeeded a number of epic poets, most of whom wrote on the subjects contained in the so-called 'Cycle,' a word which seems to designate a collection of epic poems confined to a certain range, commencing with the union of heaven and earth, and ending with the latest adventures of Ulysses in Ithaca. The whole depended on Homer's so-called 'Trojan Cycle.' After the period of the Olympiads, the 'Cycle' seems to have declined, and for three centuries the great lyric poets were most conspicuous. Roman epic poetry, like most of the literature and civilization of that people, received its first impulse from Greece. Livius Andronicus and Cneius Nævius, who translated epic as well as dramatic poetry into Latin, were both probably Italian Greeks. Ennius too, the real founder of the Roman epos, was born at Rhudiæ in Calabria. It is probable that he first substituted the hexameter for the old Saturnian measure. No remains of Latin epic poetry between Ennius and Virgil have been preserved. In the latter author we find the reflexion of Greek poetry on the polished surface of the age of Augustus. Though exquisitely beautiful, the 'Æneid' is something almost entirely different in tone and spirit from Homer, and bears traces of its exotic growth, just as the Spanish poetry, after the time of Garcilasso de Vega, savours of Italian influence. The principal Latin epic poems after Virgil are the 'Pharsalia' of Lucan, the 'Argonautica of Valerius Flaccus, the 'Punica' of Silius Italicus, and the 'Thebais' of Statius. Some of Ovid's works, such as his 'Metamorphoses,' must be included in the general definition of epic poetry given above.

In modern poetry we find certain subjects which strongly remind us of the 'Cycle' in the mode in which they have furnished a constant set of themes for the poets of the middle ages. Such are the exploits of Arthur and Charlemagne, with their kindred legends. The cycle of Arthur was probably derived from the Celtic tribes, who seem to have sought in the exploits of their champion and the prospect of his restoration an indemnity for the sinking fortunes of their race. What they had lost in reality they made up in fiction, and communicated the interest in their own hero to the invaders who encroached on their borders.

The oldest Teutonic epic is the 'Nibelungen Lied.' It is composed in rhyming strophes of four lines each. The circle of tradition of which it treats was widely extended, and probably came from the north. The characters have a wild gigantic air, and the feeling of the poem, though the scene is laid in a Christian time and country, is, as Goethe has observed, purely heathen. There is no trace of any moral influence of religion. The 'Nibelungen Lied,' in its present form, was probably composed in the time of the Hohenstaufens, about 1200 A.D.

The poem of the 'Cid' is another remarkable monument of early modern epic poetry. Mr. Southey says, 'It is unquestionably the oldest poem in the Spanish language. In my judgment it is decidedly and beyond all comparison the finest.'

The mass of epic poetry existing in the Eastern languages seems very large. The most celebrated compositions of this class in Sanscrit are the 'Mahâbhârrata' and the 'Râmâyana.' Persian literature boasts the 'Shah Nâmeh' of Firdusi (who lived about 960-1030 A.D), in 60,000 verses. The 'Moallakât,' or collection of seven poems anterior to the time of Mohammed, of which 'Antar' is one, is said to be hung up in the Caaba of Mecca.

With the exception of our own Milton and of Camoens, the most celebrated modern epics are those of the Italian poets. The union of the classic and romantic elements in modern poetry began in Pulci, the friend of Lorenzo de' Medici (died 1487). To him succeeded Boiardo and Ariosto. The groundwork of their fictions was the cycle of Charlemagne as developed in the yet popular story-book the 'Reoli di Francia.' The coarseness and exaggeration of Pulci are softened down into exquisite irony and naïveté in Ariosto. In both writers there is somewhat of the same humorous feeling which in Cervantes formed the basis of 'Don Quixote.' Tasso imitated the antients most profusely, but he wove his imitations into an organic whole. His poem is composed with the utmost regularity, and appeals to the tender feelings and Christian sympathies of his age and country. The influence of the Italian poets on our own literature in the case of Spenser, Milton, and other writers, is most marked. In later times, in Germany, Klopstock followed in the footsteps of Milton. It is scarcely necessary to mention the 'Henriade.' Scott's poems have a strongly marked epic spirit. In Byron the morbid feeling of the individual is too often visible through the thin web of the story, and we miss much of the 'objective' character essential to epic and narrative poetry.

2. The analogous origin of the drama in antient and modern times is remarkable enough. In Greece it sprang from the religious ceremonies connected with the worship

of Bacchus: tragedy and comedy began respectively with the performers in the Dithyrambic and Phallic hymns. The modern drama arose out of the Mysteries of the middle ages, and in a single country of Europe the genius of the people caused it to retain its religious character to a very late period. The 'Autos Sacramentales' of Calderon, written at the end of the seventeenth century, at the court of the Spanish Bourbons, were genuine devotional ceremonies. The Ave Maria and the prayer on the stage were meant to be real, though the work in which they were introduced was professedly a fiction. It is rather difficult to ascertain what Aristotle meant when he said that 'tragedy effected the purification (κάθαρσιν) of the passions by means of fear and pity.' If we compare the passage in the eighth book of the 'Politics,' in which he uses the same expressions with reference to music, it will be clear that he did not mean, as has been supposed by some, the exercise of our passion on proper objects. We believe that he intended to describe that co-existence of excitement with an overbalance of pleasure to which we have already alluded. Fear and pity, when excited by the reality, do to a certain degree degrade or destroy the equilibrium of the mind: when properly appealed to by music or poetry, they cease to stagnate, and are at the same time 'purified' of all noxious and painful action; they are exercised consistently with the supremacy of reason and the enjoyment of pleasure by the individual himself.

The question of the unities in the drama is closely connected with that of illusion referred to above in its relation to art in general. There can be no doubt but that unity of action is essential, but that Aristotle rigidly prescribes the unities of time and place is untrue, and inconclusive if it were true. To turn a representation of three hours into a whole day is a contradiction of reality differing only in degree from imagining the same space to represent a lapse of years; but the fact is that illusion, or the notion that the action is a real one, is not to be aimed at. The imitation must in the ordinary drama be *probable*, or it ceases to be imitation; but we make as it were a tacit bargain with the poet to waive the limits of time and space. We play at a game on certain conditions subject to which he is to compose, and we are to look on. Thus in different classes of the drama these conditions vary. In the antient comedy, in an opera where the slender thread of words merely guides the stream of music, in a masque such as 'Comus,' or in a pantomime, who asks for probability? The writer engages to transplant us into a new and strange world; that world must be *consistent with itself*, and the writer must possess sufficient power and imagination to carry us into the region which he professes to people. The French, having long resisted the natural freedom of the imagination, are now paying the penalty of artificial constraint by the extravagance of their romantic writers. The reader will find excellent remarks on dress, scenery, and acting, and their relation to the poetry of the drama, in some of Charles Lamb's 'Essays.'

The histories of Shakspere are a distinct class of dramatic composition; dramatic in their form, and possessing a dramatic interest and crisis, but resembling epic works in their episodical character. To deny them their own merit because they are not what is called 'the regular drama,' is like the one-sided exclusiveness of taste which despises a Gothic cathedral simply because it is not a Greek temple. The beautiful in art is not confined within such narrow limits.

In the antient tragedy there is generally a solemn and gloomy destiny hanging over the story from its commencement. Some old unexpiated crime weighs down the hero and his house; the highest qualities of the human soul are exhibited in his struggles with fate, until the whole closes in darkness and destruction. The chorus was a peculiar feature, rendering, it may be observed, all notion of illusion doubly absurd. Its fate, Twining remarks, was curious; first it was all, then it was relieved by dialogue, then subordinate to dialogue, then digressive and unconnected with the subject of the play, for Aristotle observes that in Euripides it ceased to be part of the piece. In its proper application in tragedy, it was a lyrical accompaniment reflecting as it were the general impression of the whole work; a sort of abstract spectator, as Schlegel calls it (idealisirte zuschauer).

The works of Shakspere, and in a far less degree those of Calderon, have exercised enormous influence in modern Germany. Their renewed study in fact roused the spirit of rebellion which has completely burst the fetters of the French school of criticism, and inspired the dramatic genius of Schiller and Göthe.

3. We have already stated that the division of poetry given above is not put forth as exhaustive or complete. We cannot pretend, in the limits of this article, to discuss all the various forms of poetical composition which have prevailed, but we shall conclude by saying a few words on the subject of popular poetry and ballads.

There are few nations so rude as not to have attempted to clothe in verse of some sort, the feelings excited by the worship of their gods, and by the dangers of the chase and the battle, or who have not pretended thus to record the exploits of their heroes. It is probable that detached strains of this kind, recited or sung to music, have always preceded the connected efforts of epic poetry. These songs, familiarised by traditional recitation, would finally be worked into a sort of cycle, like the ballads of 'Robin Hood,' and might in certain cases become the basis of larger compositions.

Ballad poetry has attracted great attention from literary men during the last fifty years. The publication of Percy's 'Relics' in this country, though not absolutely the first attempt of the kind, roused the taste of Germany. Bürger translated many of the pieces contained in that collection. Herder's 'Volkslieder' gave an additional impulse to the study, and his masterly version of the ballads of the 'Cid' has become a German classic. The Germans repaid to us the debt which they owed for the first step; Bürger's 'Lenore' and his other works reacted on Scott. In the 'Border Minstrelsy' and the researches connected with it, a new field was opened, and Scott caught thoroughly the spirit of the old stirring songs which he took such pleasure in collecting and editing.

The Danes, the Germans, and the Sclavonian nations, especially the Servians, have a good deal of old popular poetry, but the two countries which are the richest in this department are Great Britain and Spain. Our own ballads are a sort of mixture of the epic and lyric compositions. The author sometimes expresses his own feelings; he does not narrate evenly and uninterruptedly, but springs as it were from one projecting point of the story to another, leaving to the imagination of the reader the task of filling up the intervals. Handed down for a long period by word of mouth, these ballads have suffered mutilation, and the later versions often vary much from the earlier ones, as may be seen, for instance, by comparing the two copies of 'Chevy Chase.' Sometimes a ballad composed for one event has been adapted to another; but on the whole, the remains which we still possess are most admirable.

The Spanish ballads are more epic in their character (we do not now speak of the Moorish ones). The lines generally terminate with an assonance instead of a complete rhyme, and they flow on in simple and strong narrative, sometimes tinged however with the national exaggeration. The principal subjects are the exploits of the peers of Charlemagne, the adventures of Bernardo del Carpio, the 'Chase of Roncesvalles,' the 'Infants of Lara,' but above all the history of the Cid and the later Moorish wars. The Spanish ballads are generally free from the gloomy supernatural machinery of northern nations. Ghosts and witches do not figure in them, as in English and Scotch popular poetry, though in one or two cases fairies occur The lighter compositions, 'coplas' and 'canciones,' are in their way just as beautiful, Some of the best seem to be fragments of old songs now lost.

Of the effect of popular poetry on the events of real life in times of revolution or disturbance it is unnecessary to speak. Those compositions which would seem to be the lightest and most trifling produce of the human imagination, are found in immediate contact with the sternest reality. Selden observes, 'More solid things do not show the complexion of the times so well as ballads and libels.' It is said that the old touching ballad of 'Ay de mi Alhama' was forbidden to be sung in the streets of Granada after the conquest. We have in Percy's collection the satirical ballad of 'Richard of Almaigne,' composed with reference to the war between Henry III. and his barons. Popular poetry played its part in contributing towards the Reformation. The absurdities and vices of the clergy were an inexhaustible theme at a later period. The song of 'Lillibulero' probably did much to facilitate the Revolution of 1688. Burnet (*Own Times*, iii. 336) says of it, 'Perhaps never had so slight a thing so great an effect.' The 'Marseillaise,' 'Ça ira,' and 'Tragala' played a still more prominent part in the bloodier convulsions of modern times.

PO'GGIO. [Bracciolini.]

POGGY ISLANDS. [Nassau Islands.]

POGO'NIAS. [Barbets.] Mr. Swainson makes the *Buccoinæ*, or *Barbuts*, a subfamily of the *Picidæ*, placing it after the *Picianæ*, at the end of the family. He characterises the *Buccoinæ* thus:—Bill surrounded with long bristles. Tail short, soft.

The following genera and subgenera are arranged by Mr. Swainson under this subfamily:—

Asthenurus, Sw. Bill short, compressed, very straight. Rictus smooth. Wings with the first three quills graduated. Tail moderate. Versatile and anterior toes nearly equal. Tropical America. (Sw.)

Example, *Asthenurus exilis*. *Pl. Col.*, 371, f. 2.

Picumnus, Temm. Habit of Asthenurus, but the rictus is bristled; the tail very short and not projecting beyond the wings. Tropical Asia. (Sw.)

Example, *Picumnus abnormis*. *Pl. Col.*, 371, f. 3.

Bucco, Linn. Bill straight, strong; the base very broad, dilated, and surrounded with long and very rigid bristles. Tarsus shorter than the versatile toe. The Old World. (Sw.) [Barbets.]

Subgenus *Micropogon*, Temm. General structure of *Bucco;* but the gape smooth. The first three quills only graduated. South America only. (Sw.)

Example, *Micropogon Cayennensis*. *Pl. Enl.*, 206, f. 1.

Genus *Pogonias*, Ill. General structure of *Bucco;* but the margin of the upper mandible distinctly toothed. Africa only. (Sw.)

Under a line of demarcation, Mr. Swainson adds the genera *Yunx*, Linn., and *Oxyrhynchus*, Temm. (*Classification of Birds.*)

Mr. G. R. Gray arranges the *Buccoinæ* as the first subfamily of the *Picidæ*, and makes it consist of the following genera:—*Pogonias*, Ill.; *Bucco*, Linn.; *Micropogon*, Temm.; *Polysticte*, Smith; and *Psilopogon*, Boie.

Pogonias is also Lacépède's name for a genus of Acanthopterygian fishes placed by Cuvier under his family *Sciænoides*.

POINCIA'NA ACULEA'TA, or the Barbadoes Flower-Fence, is a tropical leguminous bush, about ten feet high, with bipinnate leaves, obovate leaflets, prickly branches, large terminal corymbose masses of inflorescence, covered with showy yellow or red flowers, having singularly long stamens. It has acquired its name from having been used, on account of its prickly branches, as a material for hedges in the West Indies, for which however it is ill adapted, because its branches are not much subdivided, and are always naked next the root. It is among the most beautiful of plants, and is chiefly on that account cultivated in the West Indies, to which it was introduced from the East Indies, where it is common in gardens, flowering and seeding all the year round. The leaves when bruised have a smell of savin, and are said to have the power of bringing on abortion. They are well known to be purgative, and to have been used as a substitute for senna. According to Roxburgh, the trunk of this little tree or large shrub, when old, is constantly hollow, and occupied by a large red dark-brown ant. From this place, when disturbed, the ants issue in swarms, and inflict a severe and painful bite on their disturbers.

POINT, in music, the subject or theme of a fugue. [Fugue.]

POINT. [Solid, Surface, Line, Point, Definition of.]

POINT OF CONTRARY FLEXURE. By this term is understood a point at which a curve changes its curvature with respect to any given external point, being concave on one side and convex on the other. [See the figure in Curve for instances.]

The mathematical test of a point of contrary flexure in a plane curve is as follows. Let $y=\phi x$ be the equation of the curve, and let y'' be the second differential coefficient of y with respect to x. As long as y and y'' have the same sign, the curve presents its convexity to the axis of x, and when y and y'' have different signs, its concavity. When y'' changes sign, there is a point of contrary flexure, if y be then finite; and this, whether it passes through zero or infinity at the change. (*Library of Useful Knowledge*, 'Diff. Calc.,' pp. 369, 370.)

It is frequently stated in elementary works, that there is a point of contrary flexure when $y''=0$, and the converse. Both propositions are inaccurate; there is not necessarily such a point when $y''=0$, and there may be such a point when y'' is not nothing, but infinite. For the reasons which make this inaccuracy common, see Taylor's Theorem.

For example, let $y=x^2-\frac{1}{x}$, which gives $y''=2-\frac{2}{x^3}$. As long as x is less than 1, y'' is negative, and so is y, whence the curve is convex to the axis of x. When $x=1$, both y and y'' vanish, and when x is greater than 1, y and y'' are both positive, so that the curve is still convex. But there is a change of sign in y'' when x passes through 1; and therefore there is a point of contrary flexure when $x=1$. It is to be remembered that though at a point of contrary flexure the curve changes curvature with respect to any line not passing through the point, it preserves its curvature with respect to every line which does pass through the point, being on both sides convex, or on both sides concave, to that line. In the present instance, the curve is always convex to the axis of x; consequently, where it has a point of contrary flexure, it cuts that axis.

At every point of contrary flexure, the Tangent passes through the curve, and has a contact of an order different from that which it usually has. The radius of curvature at a point of contrary flexure is always either nothing or infinite.

Some English writers have copied the continental ones in calling it a point of *inflexion*.

POINT DE GALLE. [Ceylon.]

POINT WELLESLEY, Province of. [Penang.]

POINTER, a variety of the Dog used in shooting, and trained to stop and point where the game lies. This variety is the *Chien d'arrêt* of the French, and the *Canis familiaris avicularis* of Linnæus.

The old Spanish pointer was slow but very sure; and after all, where game is plentiful, there is as much or more to be picked up before one of these heavy but staunch dogs, now rarely to be found, as with the modern breed, in which swiftness is carried almost as far as it can be. Not that some of these thorough-bred fine-sterned dogs are not as staunch as any pointer of the old school, and there is something very delightful in their dashing style of ranging. A well-bred modern English pointer with a strong cross of the fox-hound, has perhaps as much 'travel' as can well be got out of four canine legs, and on light lands is of great endurance; whilst the true descendant of the perfect Spanish Pointer was rarely good for a second day's work. That the fine-sterned modern pointer is staunch, all who have seen high-bred and well-broken dogs act will allow; and it is recorded of Pluto and Juno, the two beauties which are immortalised in Daniel's 'Rural Sports,' that they kept their point while Gilpin took the sketch from which the picture was painted, upwards of an hour and a quarter. Steady enough this: but, on the other hand, though blood will do much, these well-bred fine-sterned dogs have been found when tried on the moors to be, though fast, not stout hunters, and unable to stand work and weather like some of their rougher brethren.

A treatise upon dog-breaking will hardly be expected here; but those who are interested in the subject will find it well treated in Daniel's 'Rural Sports,' 'The Sportsman's Cabinet,' Colonel Hawker's well-known and excellent work, and more particularly in 'Observations on Dog-Breaking,' by William Floyd, gamekeeper to Sir John Sebright, Bart., every word of which is worthy of the best attention. There are also many valuable hints in the 'Treatise on Shooting,' by the author of the 'Oakleigh Shooting Code,' in 'The Rod and the Gun.'

POISON. Separate articles having been devoted to nearly all the substances which are destructive to life when taken by accident or design, or when administered with a criminal intention, it will be necessary here only to consider the subject of poisons generally, referring to the articles Arsenic, Antimony, Copper, Mercury, Papaver, &c. for the details relating to each of them in particular. The whole subject may be conveniently and usefully treated by pointing out how in any case of legal investigation the proofs of poisoning may be established.

Omitting those things which are common to all cases of suicide or homicide, such as the previous circumstances of the person supposed to be poisoned, the conduct of the accused, and those, however important they may be, that are matters of common evidence, such as a number of persons who have partaken of the same meal being simultaneously and similarly affected, we propose to consider here only how in any individual case the influence of poison may be proved. The chief circumstances in the evidence will be, the symptoms presented during life; the examination of the body after death; the chemical analysis of the substances in which the poison may be mixed; and the experiments by which it is attempted to produce similar circumstances in animals by similar means.

The circumstances that usually first excite the suspicion of poison having been taken are, that the person affected is suddenly attacked by symptoms of severe illness, which come on soon after eating or drinking, without any premonitory indications, which regularly increase in severity without undergoing any important change in their character, and which rapidly prove fatal. All these however are far from affording sufficient evidence of poisoning. Suddenness of attack is common to many disorders, as cholera (whether ordinary or Asiatic), plague, perforating ulceration of the digestive canal, apoplexy, and epilepsy; and even in some cases of fever the premonitory symptoms are too slight to attract the attention of the patient. Any of these too may come on soon after taking food, and while the patient is apparently in the enjoyment of health; this is especially the case with cholera, perforation of the stomach, and apoplexy; and even in some diseases of the heart the patient may seem well up to the instant of the fatal, and often instantly fatal, seizure. The permanency and regular increase of the symptoms is not a more distinctive sign of poisoning. It is equally observed in many cases of the diseases already mentioned, as well as in most acute and uncontrolled inflammations, strangulation or other obstruction of the intestines, &c. Many of these diseases also may prove very rapidly fatal; apoplexy and certain diseases of the heart sometimes destroy life in a few seconds, and often in a few hours; in almost all cases of perforation of the digestive canal, and in some of cholera, death takes place in less than twelve hours.

In no case therefore can these, which are commonly stated as general symptoms of poisoning, excite more than suspicion; they may all have been produced by some spontaneously occurring disease. But on the other hand, the absence of any or all of them is not sufficient to disprove the suspicion of poisoning. Small and often repeated doses of poison may be given so as to produce all their symptoms and death very gradually; and the patient may in such a case exhibit numerous alternations of increase and moderation of the symptoms. Many circumstances will retard the action of even large doses of poison; if a person falls asleep soon after taking one, or if he has taken it with a large quantity of food, or much diluted, or partially neutralised, its symptoms may not be developed for some hours, and may seem quite unconnected with the last occasion of taking food. Or again, the poison may be administered in some other way than with food or medicine, as in the form of a vapour, by applications to the ulcerated skin, &c.

Dr. Christison divides poisons into three classes, irritants, narcotics, and narcotico-acrids. Each of these produce certain symptoms in addition to those already mentioned as belonging to poisons of all kinds, and certain morbid effects upon the organs of the body when it proves fatal, by which their action may in some cases be recognised.

The chief symptoms caused by the internal administration of irritant poisons are those of severe irritation of some or all parts of the alimentary canal. They commonly excite burning heat, redness and swelling and sometimes ulceration of the lining of the mouth, throat, and tongue; difficulty of swallowing, burning pain of the stomach with nausea and retching or vomiting, tenderness on pressure and tension of the upper part of the abdomen. The matters vomited consist, first, of the food or other contents of the stomach, and afterwards of tough mucus with more or less of blood and bile; the sickness is almost incessant, and is usually accompanied by severe suffering. The pain commonly extends from the stomach along a part or the whole of the digestive canal, with tenderness on pressure, and usually a constant and painful diarrhœa of mucus with more or less blood. The pulse is quick and feeble; there is great prostration of strength, excessive burning thirst, cold and damp skin, extreme anxiety of countenance and manner, and often considerable difficulty of breathing.

Many or all of these symptoms occur in al cases of poisoning by irritants, and many of them also in certain diseases, between which and poisoning it may be difficult to discriminate. Of these diseases the most important and deceptive are the acute affections of the digestive organs.

The most general effect of irritant poisoning is acute inflammation of the stomach, and it is therefore a question of the first importance whether that condition is ever produced by any other cause than the administration of poison. M. Louis and Dr. Abercrombie, whose authority is of the greatest weight in subjects of this kind, have never seen a case of idiopathic and primary acute gastritis; and it is certain that no well-established case of the kind has yet been recorded: the administration of an irritant poison may therefore be regarded as highly probable in any case in which a competent observer finds the signs of an acute inflammation of the stomach during life and its effects after death.

In such cases the principal evidence would depend on the appearances found in the dead body; in others the symptoms during life are equally important. Perhaps of all the diseases which give rise to the suspicion of irritant poisoning, the most frequent is cholera. There are however some circumstances by which they may be distinguished during life. In most cases of this kind of poisoning a burning sensation in the throat is perceived directly after the poison is taken, being the effect of its contact during or soon after the act of swallowing; the same symptom, when it occurs in cholera, appears to be produced by the contact of the substances vomited, and is therefore preceded by some of the other symptoms. In cholera the vomiting is never bloody, and is usually much more profuse than in cases of poisoning; and the cholera that occurs in this country is very rarely fatal in less than three days; while in most cases of poisoning, in which the symptoms are sudden and severe, death ensues in a few hours, or at least before the end of the third day. Asiatic cholera indeed is commonly more rapidly fatal; but it may be distinguished by the absence or late occurrence of the burning pain of the throat, by the absence of vomiting of blood, by the peculiar expression of the countenance and condition of the body, and by the suppression of all the secretions except the characteristic discharges from the stomach and intestines. [CHOLERA.]

The symptoms of common peritonitis and of common acute enteritis [PERITONITIS; ENTERITIS] can scarcely lead a competent witness of them to suspect that they arise from poisoning. But those of peritonitis from rupture or ulcerative perforation of any of the abdominal organs may closely resemble them, and render a diagnosis very ambiguous without the evidence of a post-mortem examination. Very severe cases of colic may also for a time simulate the effects of poison; but the frequent intermissions of their symptoms, the absence of both the local and the general signs of inflammation, and their rarely dangerous character or fatal termination, are sufficient signs of distinction. In the cases which have been called ileus, and regarded by some as merely examples of severe colic, there may be some doubt till the examination after death shows them to have resulted from an obstruction of the intestinal canal. [ILEUS.]

Other cases which are usually mentioned as simulating the effects of irritant poisoning, are those in which the stomach having been greatly distended by gluttonous feeding, death has occurred suddenly from apoplexy or some unknown influence; and those in which death occurs from drinking cold water while over-heated. In the former cases death, if not produced by distinct apoplexy, is preceded by symptoms more like those of narcotic than those of irritating poison; in the latter, the symptoms are very like those of common cholera, and are in the same respects different from those of poison.

It is evident from these circumstances, that in a fatal case of suspected poisoning by an irritant substance, it will seldom be possible to decide upon the evidence of the symptoms alone. When poison has actually been taken, the symptoms are sometimes so modified by circumstances peculiar to the case, that even where they have been carefully observed, much doubt has remained respecting their cause: and, on the other hand, the symptoms of naturally excited disease often too closely resemble those of poison to permit a positive conclusion being arrived at. Cases very rarely occur in which (unless other circumstances not connected with the condition of the patient after the seizure are conclusive) the evidence of post-mortem examination is not absolutely necessary.

The most general morbid appearances produced by the irritant poisons are either the destruction, by corrosion, of the tissues over which they pass, or some of the effects of acute inflammation in them. Of the latter, that which is the least decisive is the most common—redness. In the stomach, no kind or degree of merely vascular redness of the mucous membrane can alone certainly prove that it has been inflamed. The most intense redness is sometimes found where the person has had no gastric affection, and may be produced in any part of the stomach by the blood settling in its vessels after death, or being obstructed in them by suffocation. It is probable also that any very slight irritant, such as wine, given shortly before death, may produce considerable redness of the stomach. Small quantities of blood may also be effused between the lining of the stomach, from any of the causes which produce general diffused redness of the mucous membrane, by congestion of its vessels; but more considerable effusions of blood, especially when they appear as if incorporated with the tissue, and are of a brown or black colour, as if charred, are almost certain signs of poison. Any appearance of blackness, or of a dark brown discolouration of the stomach, as if from a chemical change in the blood filling its small vessels, is also a very suspicious, though not a certain sign. When redness of any part or of the whole of the lining of the stomach is accompanied by the secretion of a large quantity of tough mucus upon it, it may be deemed suspicious, but it is by no means a conclusive evidence of poison; it is more nearly so when the mucus is stained or streaked with blood. An effusion of lymph on the lining of the reddened or blackened stomach is decisive of inflammation; and of poisoning, if, as is most probable, acute inflammation of the stomach never arises from natural causes. The effusion of lymph however is not a common effect of poison, and tough mucus is often mistaken for it; they may be distinguished by the former being ropy, glaring, and transparent, the latter opaque, white, and deposited in a tender brittle membrane or in irregular flocculi. The softening of the mucous membrane of the stomach, and the ease with which it may be separated from the subjacent tissues, are signs of inflammation, when combined with an intense bright redness, or the effusion of much mucus or lymph; without coincident redness they are not to be depended on, since they may result from the digestion of the walls of the stomach, which sometimes takes place after death. An increase of thickness in the mucous and other membranes, by the effusion of serum beneath them, is a suspicious but far from a conclusive sign of acute inflammation.

The more serious changes resulting from poisons, such as ulcers and perforations of the stomach, differ according as they have been produced by the corroding power of the substance taken, or by the inflammation which it has excited. In the case of corroding substances, a principal sign by which their effects would be distinguished from ulcers which are the results of disease, is, that every part of the digestive canal with which poison has come in contact is affected at the same time, the lips, mouth, œsophagus, stomach, and even the intestines, all showing more or less of their influence; whereas it is very rare for diseases to affect more than one of these parts at a time. The appearance of an ulcer, or a perforation of the stomach, produced by corrosion, is also peculiar; it is commonly large and irregular; its edges are soft and pulpy, and usually black or brown, as if charred; and if the patient has survived only an hour or two, signs of acute inflammation will be seen in its neighbourhood, and in all the parts to which the corroding material has obtained access. Similar signs of acute inflammation are also always observed in the ulceration or perforation which sometimes, but very rarely, is produced by poisons that merely irritate the digestive canal; and these are a part of the signs by which those effects of poison are to be distinguished from perforations that occur naturally.

Ulceration and perforation of the stomach are so rarely the effect of merely irritant poison, and so commonly the effect of disease, that, unless there be signs of corrosion, they afford evidence against, rather than for, the suspicion of poison; and if there be no other evidence, and no attendant sign of recent acute inflammation, they may even be regarded as proofs that such a suspicion is incorrect. Of the forms of perforation of the stomach from other circumstances than poisoning, one of the most important is that in which, without any material alteration in the surrounding parts, one or more small ulcers form in the stomach, and becoming gradually deeper, at last, by a minute aperture, make their way through its walls, and permit its contents to escape slowly into the abdomen. These may be known at once to be the effects of disease, by the complete absence of any sign of inflammation in the lining or other tissue around them. Another form is accompanied with thickening of a considerable extent of the tissues adjacent to the ulcer, which is from a quarter to half an inch in diameter, and perforates by a large orifice, forming a hole with smooth edges, as if a piece of the stomach had been cut out by a sharp instrument. The thickening around the ulcer, which has all the characters of chronic inflammation, and the appearance of even a commencement of cicatrization, with the absence of all signs of acute disease of the stomach, are usually quite sufficient to distinguish this form of perforation. A third, which can scarcely give rise to doubt, is that consequent on cancerous or other malignant disease of the stomach. A fourth is that in which a portion of the walls of the stomach is dissolved or digested by the gastric juice after death; but whatever uncertainty there may be respecting the circumstances under which this singular effect is produced, there ought to be none in distinguishing it from the effects of poison.

From these statements it will appear that in some cases the symptoms and morbid appearances together may prove that irritating poison has been taken. The diseases in which the similarity of the symptoms is most embarrassing, as cholera and peritonitis, are those in which the morbid appearances are most distinct from perforation of the abdominal organs; while those more chronic inflammations of the stomach in which the morbid changes of structure are least decisive are those in which the symptoms admit of little doubt. This however cannot apply to all, though it may to the majority of cases. When death is produced slowly, the symptoms may be obscure, and the morbid changes very like those of disease: and still more difficult cases occur in which poison is taken by those who already suffered from disease of the stomach; or in similar individuals, deceptive appearances may be produced by the digestion and other changes in the stomach which occur after death. Cases of these kinds form a numerous class, in which the test of chemical examination, which indeed should be neglected in none, can alone be conclusive.

For this part of the subject however no general rules can be laid down. The detection of each poison must depend on the proper application of its appropriate tests; and these will be found in the several articles already referred to. [Arsenic, &c.]

The symptoms produced by the different narcotic poisons are more varied than those of the irritant class. The most common are giddiness, headache, obscurity or depravation of the sight, stupor or perfect insensibility, loss of power of the voluntary muscles, or convulsions of various kinds, and, towards the close, complete coma. To these the several species of narcotic poisons add effects peculiar to themselves; yet not so remarkable but that they are closely simulated by those of some naturally occurring diseases. The symptoms of apoplexy, for example, are almost exactly similar to those of poisoning by opium and the substances allied to it. In certain cases however the following circumstances may distinguish them. Apoplexy, though its actual attack is sudden (which the effects of opium are not), is often preceded by warning symptoms, such as headache, occasional giddiness, &c. If so severe as to simulate poisoning, it is not possible to arouse the patient from his stupor; but in poisoning with opium this may usually be effected to within a few hours of death; in apoplexy, convulsions often occur, in poisoning with opium, never; in the former the pupil is commonly dilated, in the latter contracted. Narcotic poisoning, if not fatal in twelve hours, is usually recovered from; apoplexy often terminates fatally after several days.

These distinctions will seldom serve further than to establish a very probable conclusion; and doubt may still remain in cases of this kind after a post-mortem examination. The evidence of poisoning afforded by it is commonly negative; the fullness of the vessels of the brain and the other slight differences from the appearances found in the average of healthy persons, that are commonly quoted as signs of the effects of narcotic poisons, are very unsatisfactory. It is probable that narcotics destroy by producing a kind of apoplexy; and in many cases the changes of structure to which they lead exactly resemble those of that disease, whether of those cases of it which are attended with effusion of blood in or upon the brain, or of those in which only the least possible alteration from the healthy structure can be detected. [Apoplexy.] Effusion of blood in the brain however is very rarely the effect of narcotic poisoning, and such an appearance would by itself afford strong evidence of apoplexy the result of disease.

The symptoms of epilepsy are often very like those of poisoning by prussic acid, and by some other narcotic and narcotico-acrid poisons, as belladonna, strychnia, &c. The following circumstances however distinguish epilepsy: the fit is often preceded by warnings; it almost always commences suddenly and violently; the patient cannot be roused from it: when fatal (which it very rarely is in a first attack), it is so only after several hours. In many cases the post-mortem examinations of epileptic patients detect no signs of disease; and in these there must always be some doubt, as this negative character is common to them and to narcotic poisoning. But in many, traces of old disease in the brain are found, which of course afford strong presumptive evidence that poison has not been taken. If a patient has died in a fit resembling those of epilepsy, and no morbid changes are found in his brain, poison must be strongly suspected, because it is very rare for such a fit, the result of disease, to terminate fatally, except in those whose brains are previously much diseased.

It is only necessary to allude to the difficulty that may at their first access exist, of distinguishing between the acute inflammatory diseases of the brain and those of the narcotico-acrid and some of the narcotic poisons. The true nature of the case is almost always evident after the first day of its duration; the poisoning is by that time terminated either by recovery or death; the disease continues its progress; and if the latter ends fatally, the morbid changes that it induces are sufficiently characteristic.

On the whole it must be concluded that the evidence afforded by symptoms and morbid appearances is less frequently conclusive in cases of poisoning by narcotics than in those where it is produced by irritants. The effects of the narcotico-acrids, which are compounded of those of the two other classes, are also in most cases as uncertain as those of the narcotics, and the difficulty with them is much increased by the present imperfection of the chemical tests of their presence in organic mixtures.

The evidence to be drawn from experiments with the substances supposed to contain the poison can rarely be needed, or be of much weight when obtained. In any case in which there is sufficient poison present to produce symptoms in any animal to which it is given, it ought to be discovered by the much more certain test of chemical analysis. This last, the evidence of chemistry, is certainly the least fallible of all; and in cases in which it can be applied, it is conclusive. These cases include the great majority of those of poisoning by irritants, and many of those by narcotics and narcotico-acrids; but in many of those by the two last classes, owing to the present imperfection of the tests for organic poisons, it is unavailing even in the most competent hands. In these also, as we have already shown, the evidence of symptoms and of the morbid appearances, is also often fallacious; and cases must frequently occur in which the evidence from all these sources together will not constitute a proof that poison has been taken. In the case of irritant poisons, on the other hand, the cases are few in which, from one or other of these kinds of evidence, their administration may not be satisfactorily proved.

We subjoin a list of the substances which should be administered in cases of poisoning, as early as possible after it has been swallowed.

Mineral acids (*sulphuric, muriatic, &c.*).—Chalk* or magnesia in water; soap and water, and afterwards milk and other diluents.

Alkalis (*soda and potash*).—Vinegar and water; almond or olive oil; any innocent acid with water.

Oxalic acid.—Large quantities of chalk or magnesia; afterwards milk and other mild fluids.

Arsenic.—Powerful emetics if vomiting has not commenced; large quantities of milk or some thick bland fluid, such as flour and water, or sugar and water.

Corrosive sublimate and other compounds of mercury.—White of eggs beaten up with water; decoction of bark or gall-nuts.

Blue vitriol and other compounds of copper.—White of eggs with water; sugar and water.

Antimony.—Large quantities of warm water or milk; decoction of bark or gall-nuts.

Nitrate of silver (*lunar caustic*).—Common salt and water

White vitriol and other compounds of zinc.—Milk; carbonate of soda in water.

Compounds of lead.—Emetics, sulphates or bi-carbonates of soda or potash in water; milk.

Laudanum and other preparations of opium.—Emetics; dashing of cold water on the face; strong coffee; forced exercise by constant walking.

Prussic acid.—Hartshorn, to be smelled and taken in small doses; chlorine; dashing with cold water.

Strychnine, and other vegetable alkalis.—Emetics; warm water; decoction of bark or of gall-nuts.

For other, as for many of these kinds of poison, it will always be right to excite copious vomiting, either by tickling the throat, or by giving a powerful emetic, such as from ten to twelve grains of sulphate of zinc (white vitriol), or the same quantity of powdered ipecacuan with one or two grains of tartarised antimony. The action of the emetic should be maintained till all the poison seems to be discharged, by repeated draughts of milk, or flour and water, or sugar and water, or some other bland fluid. For the subsequent treatment no general rules can be given.

POISSY. [Seine et Oise.]

POITIERS, a town in France, capital of the department of Vienne, on the river Clain, a feeder of the Vienne, 183 miles in a direct line south-west of Paris, or 214 miles by the road through Orléans, Blois, and Tours; 46° 36′ N. lat., 0° 20′ E. long.

This town was known to the Romans by the name of Limonum [Λίμωνον, Ptol.] or Lemonum (Cæsar) or Lemuno (*Tab. Peutinger*), and was the chief town of the Pictones, or Pictavi, a Celtic nation, whose name was, at a latter period, given to the city, whence the modern forms of Poitiers for the town, and Poitou for the province in which it is situated. The Pictones submitted to Cæsar at an early period of his command (Cæsar, *De Bell. Gall.*, lib. iii., c. 11), but afterwards sent eight thousand men to the general confederacy of the Gauls under Vercingetorix (B.C. 52). In the following year Duratius (B.C. 51), a chief of the Pictones, who with part of his countrymen had remained faithful to the Romans, was besieged in Limonum by the insurgent Gauls under Dumnacus, a chief of the Andes, or people of Anjou. The siege was raised by the approach of C. Caninius Rebilus, one of Cæsar's lieutenants, whose camp Dumnacus vainly attempted to storm; but the force of Caninius being insufficient to do more than repel the enemy from his camp, Dumnacus resumed the siege of Limonum, and was only driven from it by the approach of Fabius, another Roman officer, with a superior force. (Cæsar, *De Bell. Gall.*, lib. vii., 75; lib. viii., c. 26, seq.)

Upon the downfal of the Western empire, the city of the Pictones repeatedly suffered. It was pillaged (A.D. 410) by the Vandals; and subsequently came into the hands of the Visigoths, who extended their dominion over all the country south and west of the Loire. In the subsequent invasion of the Visigothic kingdom by Clovis, the vicinity of Poitiers was distinguished by the first of the three great contests that have rendered it the most remarkable battle-field of France. Alaric, king of the Visigoths, was defeated and killed by Clovis at Vouglé, which we take to be Vouillé, a village on the river Auzance, a few miles west of Poitiers. In A.D. 732, the suburbs of Poitiers were laid waste by the immense host of invading Saracens, under Abd-el-rahman; but the invaders were defeated by the Franks under Charles Martel, in the second of the engagements which have rendered the name of Poitiers memorable. The slaughter of the Moslems was great; but the victory was dearly bought, and Charles did not venture to pursue the retreating enemy. The tide of Mohammedan conquest was however checked, and western Europe was saved from the Mohammedan yoke. In the ninth century, Poitiers was pillaged by the Normans; it was at this time the chief town of an important county. [Poitou.] In the wars of the English in France, under Edward III. and his son Edward the Black Prince, Poitiers was the scene of the third memorable engagement. A body of above 2000 men-at-arms, and 2000 light infantry, partly English, but chiefly Gascons, and 4000 English archers, had advanced from Bordeaux, under the Black Prince and Sir John Chandos, almost to the

---

* In any cases in which chalk is recommended, the plaster of the ceiling or walls of a room rubbed into powder and mixed pretty thickly with water may be used with equal advantage.

Loire. In their retreat, they were intercepted near Poitiers by the French army of about 50,000 fighting men under their king Jéan II. (A.D. 1356) and his four sons. The valour of Edward, the experience of Chandos, and the superior skill and efficiency of the English archery, obtained a complete victory. Jéan himself, his youngest son Philippe, thirteen counts, an archbishop, seventy barons or baronets, and two thousand men-at-arms were taken; and eleven thousand men, including a great number of nobles, fell in the battle or the pursuit. The English and Gascons lost nine hundred men-at-arms, and fifteen hundred archers. The courtesy of the Black Prince to his royal captive, which is vividly described by Froissart, won for him universal applause. The captivity of the king, a heavy sum for the ransom of the captive nobles, and an immense booty, constituted the only results of the victory; the conquerors returned to Bordeaux too much weakened for further operations, and anxious rather to secure what they had got, than to obtain further advantages. Poitiers was surrendered to the English by the treaty of Bretigny (A.D. 1360), but reverted to France by the voluntary surrender of the townsmen, in 1372, to Charles V., who, in consideration of this act, granted them great privileges. In the religious wars of the sixteenth century, the townsmen, who had chiefly embraced the Huguenot side, suffered much from the cruelty of the Roman Catholics, who besieged and took the town. Admiral Coligny afterwards endeavoured to retake it, but without success.

Poitiers stands on a stony hill, at the confluence of the rivers Boivre, or Bièvre, and Clain. It is surrounded by an antient wall, enclosing an oblong area of sufficient extent for a population of 80,000 or 100,000; but the area is now occupied more by gardens, paddocks, and meadows, than by houses. There are six gates, four of which are connected with as many bridges over the Clain. The streets are crooked, and wretchedly paved, and most of them steep. The squares are small, irregular, and mean, with scarcely an exception. The houses are of the most antient character, such as are seen in villages, without regularity, taste, or convenience. Yet, notwithstanding these drawbacks, the town, from the air of antiquity which pervades it, from its advantageous situation on the slope of a hill, and from the winding course of the two rivers, presents, when viewed from the adjacent eminences, a very picturesque appearance. The public walk called Le Parc de Blossac, on the banks of the Clain, commands a beautiful prospect, and the public buildings of the town are interesting from their antiquity, if not remarkable for beauty. Near the city, on the south side, there are some arches remaining of a Roman aqueduct, and in the town are the scanty ruins of a Roman amphitheatre. Some towers remain of the Gothic castle, which, in the middle ages, defended the place, and which are now converted into a depôt for gunpowder. The town-hall is an ancient building, but of no architectural pretension. The cathedral is very antient. It was commenced by Henri I. of France (A.D. 1042, 1060), and finished more than two centuries afterwards. The nave is wide, but not sufficiently lofty, supported on sixteen pillars, which separate it from the broad side-aisles, each nearly as high as the nave itself. The architecture is distinguished by simplicity and boldness; but the organ-loft is modern, and ill accords with the general character of the building. The rich treasures and numerous monuments of this church have disappeared. Another church, that of St. Jéan, is of great antiquity: it has been once a baptistery. The church of Sainte Radegonde is remarkable for its wide and handsome nave without pillars.

The population in 1831 was 23,128; in 1836, 22,000. Poitiers is not a place of much business. Common woollen cloth, coarse flannel, and blankets; cotton wicks for lamps and candles; hosiery, hats, and lace; leather, sheep-skins and goose-skins with the down on for trimming, are made or prepared, though not to any great extent. Considerable trade is carried on in trefoil and lucerne seed; corn, wine, wool, flax, hemp, honey, and wax. There are two weekly markets, and two, or according to other authorities, six fairs in the year. There are quarries of freestone in the neighbourhood. Poitiers is the seat of a Cour Royale and an Académie Universitaire, which have jurisdiction over a circuit comprehending the departments of Vienne, Charente suférieure, Deux Sèvres, and Vendée, and of a bishopric, the diocese of which includes the departments of Vienne and Deux Sèvres: the bishop is a suffragan of the archbishop of Bordeaux. There are a subordinate court of justice and a commercial court, several fiscal or administrative government offices, a chamber of manufactures, a society of agriculture, commerce, and arts; a faculty of law attached to the Académie Universitaire; a royal college with a cabinet of natural history attached to it; a diocesan seminary for the priesthood; secondary schools of medicine, surgery, and pharmacy, with a cabinet of natural history; a public library of 22,000 vols.; a free-school for drawing and architecture; a botanic garden, where lectures are given; a departmental nursery; several hospitals; a maternity society, and a theatre.

The arrondissement of Poitiers has an area of 760 square miles, and comprehends 82 communes. It is divided into ten cantons or districts, each under a justice of the peace. The population in 1831 was 94,770; in 1836 it was 95,059.

POITOU, a province and military government of France before the Revolution. It was bounded on the north by Anjou, on the north-east by Touraine, on the east by Berry and Marche, on the south-east by Limousin, on the south by Angoumois and Saintonge, on the south-west by the district of Aunis, on the west by the ocean, and on the north-west by Bretagne. Its form was irregular, extending in length 165 miles, from north-north-west to south-south-east, from the coast opposite the little island of Noirmoutier (which, with the Isle of Yeu, belonged to Poitou) to the neighbourhood of Rochechouart, and in breadth about 83 miles, from the banks of the Creuse, a little above its junction with the Vienne to Aunay near St. Jéan d'Angély. It was divided into Le Haut Poitou, or Upper Poitou, and Le Bas Poitou, or Lower Poitou; of which Poitiers (population 22,000) and Fontenay (population 7650) were respectively the chief towns. Le Haut Poitou comprehended the districts of Haut Poitou proper, Le Loudenais, Le Merebelais, Le Thouarsais, Le Niortais, or territories of Loudon (population 5032), Mirebeau, Thouars, and Niort (population 18,197); and La Gastine or Gâtine, of which Parthenay (population 4288) was the chief town. Poitou is now included in the departments of Vienne, Vendée, and Deux Sèvres. Some very small portions are included in the departments of Indre et Loire, Charente, and Haute Vienne. The population given above is that of the communes, and from the census of 1836.

Poitou was included by the Romans in the province of Aquitania Secunda, and from them it passed successively to the Visigoths and the Franks; and upon the dismemberment of the Frankish monarchy under the Merovingian and early Carlovingian princes, it was included in the kingdom or duchy of Aquitaine. Under Charlemagne (and indeed earlier) it constituted the county, or part of the county, of Poitiers; and in 845, by treaty between Charles le Chauve and his nephew and feudal subordinate Pepin, king of Aquitaine, the provinces of Poitou, Saintonge, and Angoumois were separated from that kingdom, and formed into what was termed the duchy of Aquitaine, as distinct from the kingdom so called. This duchy was conferred upon Rainulfe or Ramnulfe I., count of Auvergne and of Poitiers, and retained its separate existence when the kingdom of Aquitaine had been reunited to that of France. Rainulfe was mortally wounded near Le Mans, A.D. 867, in battle with the Northmen, or Normans, whose ravages were at this time at their height. He was succeeded in the county of Poitiers and duchy of Aquitaine by Bernard II., who was expelled by Louis le Bégue, king of France (A.D. 880), and succeeded by his son Rainulfe II. This count refused obedience to Eudes, who had usurped the throne of France (A.D. 887), and caused himself to be proclaimed king of Aquitaine; but he subsequently made up his quarrel with Eudes. He is said to have died from the effect of poison administered by the direction of Eudes (A.D. 893): and the county of Poitiers, after being contested by Adémar, or Aymar, and Robert, brother of King Eudes, came (A.D. 902) to Ebles the Bastard, a natural son of Rainulfe II. Ebles subsequently became duke of Aquitaine and count of Auvergne and of Limousin; but before his death (A.D. 832) he was despoiled of all his honours and dominions except the county of Poitiers, in which he was succeeded by his son Guillaume I., surnamed, from his abundance of light hair, Tête d'Etoupe ('head of tow'). Tête d'Etoupe was compelled for a time to share his county with Hugues le Grand, count of Paris; but having supported the king Louis IV. d'Outremer against Hugues, he succeeded by the king's grant in recovering the sole authority in his county, to which he added the county of Auvergne and the duchy of Guienne on the death of Raymond Pons, count of Toulouse, who had possessed these dignities. The lords of Guienne and the people of Auvergne however, being attached to the house of Toulouse, refused to acknowledge Guillaume, though Louis d'Outremer had invested him with the duchy; and Hugues le Grand, count of Paris, prevailed on Lothaire, who had just succeeded Louis, to grant the duchy to him. Hugues and Lothaire advanced with an army into Poitou, and laid siege to Poitiers (A.D. 955); but the siege was unsuccessful, though the invaders cut to pieces the army of Tête d'Etoupe, who attacked them on their retreat. Tête d'Etoupe ultimately succeeded in possessing himself of the counties of Auvergne and Le Velay, and of the duchy of Aquitaine, in which last, as well as in his county of Poitiers, he was succeeded (A.D. 963) by his son Guillaume II.

Guillaume II., surnamed Fier-à-bras (Fera brachia, or Ferox brachium) from his great strength, was obliged to cede Loudon and some other places to Geoffroi, count of Anjou, by whom he had been beaten in battle (A.D. 985). He refused to acknowledge the title of Hugues Capet to the crown; and in consequence Hugues invaded Poitou and laid siege to Poitiers (A.D. 988 or 990), but was obliged to raise the siege, and effected his retreat with some difficulty. Fier-à-bras made peace with Hugues Capet, and soon afterwards abdicated his honours and retired to a monastery, being succeeded by his son Guillaume III., surnamed Le Grand, to whom he is said to have bequeathed not only the county of Poitou and the duchy of Aquitaine, but likewise the counties of Limousin and Saintonge and the district of Aunis. Guillaume le Grand acquired by marriage, according to some authorities, the county of Marche, and extended his territories from the Atlantic to the Rhône. By a subsequent marriage he acquired the duchy of Gascogne; and, by a third marriage, allied himself to the house of Bourgogne. He was the most powerful of the French grandees of his time. The nobles of Italy offered him the crown of that country; but finding that the offer was by no means a unanimous one, he declined accepting it. He was held in high esteem by the princes of western Europe; and in a barbarous age was a cultivator and a patron of letters. On his abdication (A.D. 1029), his county of Poitiers and duchy of Aquitaine passed to his son Guillaume IV., surnamed Le Gras.

Guillaume le Gras was engaged in war with Geoffroi Martel, count of Vendôme, and afterwards of Anjou, who had married the widow of Guillaume le Grand, and pretended an hereditary right to the county of Saintonge. Geoffroi penetrated to Poitiers, the suburbs of which he burned; and having defeated Guillaume at Moncontour (A.D. 1034) and taken him prisoner, released him only on condition of his ceding the counties of Saintes and Bordeaux, and paying a ransom. Guillaume le Gras died A.D. 1038.

Eudes, son of Guillaume le Grand by his second wife, who had inherited from his mother the duchy of Gascogne, succeeded his half-brother Guillaume le Gras in the county of Poitiers and duchy of Aquitaine. He engaged in a war with Geoffroi Martel, in order to recover the counties of Bordeaux and Saintes, but was killed while besieging a castle in the district of Aunis. Guillaume V., surnamed Aigret and Le Hardi, a son of Guillaume le Grand by his third wife, succeeded Eudes in the county of Poitiers and duchy of Aquitaine (A.D. 1039), but not in the duchy of Gascogne, of which Bernard, count of Armagnac, possessed himself. He too was engaged in war with Geoffroi Martel: and was compelled to associate with himself in the duchy of Guienne his own brother Gui-Geoffroi, who had previously acquired the duchy of Gascogne by the expulsion of the count of Armagnac. On the death of Guillaume le Hardi, Gui-Geoffroi succeeded, and took the name of Guillaume VI. (A.D. 1058.) He united under his government a considerable portion of the south-west of France, and recovered the county of Saintes from the house of Anjou: the county of Bordeaux had been previously restored. He died A.D. 1086, and was succeeded by his son Guillaume VII., called Le Jeune.

Guillaume le Jeune assumed the title of count of Toulouse in right of his wife, who was daughter of Guillaume, brother and predecessor of Raymond, the reigning count, and, during the absence of Raymond, who was engaged in a crusade [LANGUEDOC], possessed himself of the county, which however he was afterwards induced to resign. Notwithstanding this failure, Guillaume retained great power: the counts of Angoulême, Périgord, Marche, and Auvergne were his vassals, and his accomplishments as a knight and poet increased the exaltation of his rank. His verses are the most antient of the extant poetry of the Troubadours, and attest the gross irregularities of the morals of that age, irregularities in which he himself largely participated. Seized with the devotion of the times, he set out for the Holy Land (A.D. 1101) at the head of an expedition of 140,000 men, who were followed by at least an equal number of women, children, and what Sismondi terms 'useless pilgrims.' This expedition was designed to strengthen the newly founded kingdom of Jerusalem, and comprehended among its leaders Anselme, archbishop of Milan; Guelph IV., duke of Bavaria; Hugues, count of Vermandois, brother of Philippe I. of France; Geoffroi, count of Vendôme; Etienne, count of Blois; Herpin, viscount of Bourges; Etienne, count of Bourgogne, or Franche Comté; and other nobles of France, Lombardy, and Southern Germany. But this immense host was diminished by the attacks of the Bulgarians, through whose territory it marched, and entirely destroyed in its progress through Asia Minor, very much through headstrong rashness and want of subordination. Guillaume le Jeune took refuge at Tarsus in Cilicia, from whence he proceeded to Antioch and Jerusalem. He returned to his dominions (A.D. 1103), and recorded his disastrous expedition in a poem now lost. The dissoluteness of his manners subsequently involved him in disputes with the church, and the restlessness of his disposition led him continually to engage in war. He conquered the county of Toulouse a second time (A.D. 1114), but his garrisons were driven out while he was in Spain with an army which contributed materially to the defeat of the Moors near Cordova (A.D. 1120). He afterwards engaged in a dispute with Louis VI. le Gros, in order to protect his vassal the count of Auvergne, whom the king had undertaken to chastise; but, alarmed at the force which the increasing power of the crown enabled Louis to raise, he hastened to make his submission (A.D. 1126). He died shortly after (A.D. 1127), as it appears of premature old age induced by his debaucheries. His son Guillaume succeeded him.

Guillaume VIII., though less debauched than his father, was as fond of war. He conquered part of the district of Aunis (A.D. 1130, seq.), and, in alliance with Geoffroi Plantagenet, count of Anjou, attacked Normandie. He died on a pilgrimage to S. Jago de Compostella in Spain (A.D. 1137), leaving his dominions to his eldest daughter Eléonore, who, after being married to (A.D. 1137) and repudiated by (A.D. 1152) Louis VII. le Jeune of France, was married, just two months after her divorce from Louis, to Henry Plantagenet, duke of Normandie, count of Anjou, and, in the sequel, king of England. The extensive territories which this marriage added to Henry's already considerable domains made him the most powerful prince of Western Europe. In 1169 he ceded Poitou, and the rest of the duchy of Aquitaine, to his eldest son Richard, afterwards Richard I. of England; but both Henry and Richard had to maintain frequent contests with their vassals, whom their own tyranny or that of their officers, or the intrigues of the French court, continually excited to rebel. The violent character and warlike spirit of Richard involved him in hostilities with the neighbouring grandees, with the French king, and ultimately with his own father Henry II. of England. After his return from the Holy Land, he granted the county of Poitiers and the duchy of Aquitaine (but not in full proprietorship) to his nephew Otton or Otho of Germany; from whom he afterwards repurchased them. On his death, the county and duchy reverted to his mother Eléonore, who was yet living, and who associated her son Jéan or John, king of England, with herself in these possessions. Otton, who appears never to have received the full amount for which Richard had agreed to purchase them, now reclaimed possession, but without success. Eléonore retained them almost, if not quite, till her death (A.D. 1203 or 1204). She had been attacked by her grandson Arthur of Bretagne, who claimed Poitou as part of his inheritance, but was defeated and taken by John at Mirebeau. Philippe Auguste, the ally of Arthur, shortly afterwards overran Poitou (A.D. 1204). Scarcely any resistance was made, and it is likely that the tyranny of Richard and the baseness of John had estranged the affections and allegiance of their vassals. Sismondi considers that the sentence of forfeiture of all his lands in France, which was pronounced against John by the court of peers of France, was subsequent to the conquest of Poitou, Normandie, and other of his territories; and that it merely gave a legal sanction to a conquest which had previously been achieved by force of arms. Thus fell the great county of Poitiers, the holders of which had played so important a part in the affairs of France.

Poitou was given by Louis IX. to his brother Alfonse, on whose death (A.D. 1271) the title of it was disputed between Philippe le Hardi, king of France, son of Louis IX., and Charles of Anjou, brother of Alfonse, and king of Naples. After a legal contest of many years, the county was adjudged to Philippe, who reunited it to the crown. Poitou was overrun by the English in the war of Edward the Black Prince in France (A.D. 1356), and was included in the principality of Aquitaine ceded by the treaty of Bretigny (A.D. 1360) in full sovereignty to Edward III. of England, who bestowed it on his son the Black Prince as a dependency of the English crown. [Bordeaux.] The defeat of the English fleet by the Castilians off Rochelle (A.D. 1372) enabled the French to reconquer Poitou. The duke of Berri and the constable Duguesclin broke into the province with their armies. Poitiers opened its gates, other places were taken by force, and Poitou finally reverted to the dominion of France (A.D. 1372). It was given by Charles V. to Jéan, duke of Berri, as an appanage; and afterwards by Charles VI. to his son Charles VII. when dauphin; but on his accession, it was reunited to the domains of the crown, from which it was never afterwards alienated. (*L'Art de vérifier les Dates;* Sismondi, *Hist. des Français.*)

POKE. [Phytolacca.]

POL, ST. [Pas de Calais.]

POLA, ANTIQUITIES OF. [Istria.] The most remarkable of the architectural remains at Pola is the amphitheatre. Though in its general plan and disposition it is nearly similar to all other edifices of the kind, it is marked by peculiarities. Like them, it is an ellipsis, and its transverse or greater axis, which runs nearly in the direction of north and south, is 436 English feet, while its lesser axis, or conjugate diameter, measures 346; consequently it falls short in size of the one at Verona, the dimensions of the latter being respectively 506 and 404 feet; yet is a trifle larger than that at Nismes, since the last does not exceed 430 by 337 feet. It is erected partly upon a rocky hill, on its eastern side, where there is only one tier of arcades, with another of square-headed openings or windows above, while the western side, or that facing the sea, has two tiers of arcades, besides an additional story beneath it, forming a series of square-headed doorways or entrances. In point of architecture it is still more remarkable, as exhibiting a specimen of that peculiar mode of bold rustic-work [Rustic] with deep channels (as well for the voussoirs of the arches as for the horizontal courses), which was afterwards so greatly affected by many of the Italian architects, and particularly those of the Florentine school; and it is further remarkable for the irregularity both of the depth of the courses of stone and of the size of the stones themselves, owing to which last circumstance their joints do not form exact *bond.* Yet in a work of such magnitude and massiveness this disregard of nice symmetry in that respect adds perhaps as much to the idea of rude strength as it detracts from finished elegance of workmanship. Both orders to the stories in arcades—if orders they can be called, for they consist only of pilasters, partly encased in the rustics of the piers, without any regular entablature, the architrave and frieze being supplied by horizontal courses of rustics—are Tuscan; and there are 72 arches in the circumference of each story, eight of which openings are placed in four projecting breaks, or *contreforts,* turned diagonally to the axes of the ellipse, and giving to the exterior a marked difference from that of other amphitheatres which are known to us. Only the external circumference is now standing, but that is nearly entire; the edifice therefore presents a fine appearance from the sea, on which side the extreme height from the ground is 101 feet, while on the east it does not exceed half that elevation.

Pola possessed also a theatre, but it is now known to us only in the rude sketches given of it by Serlio, in his work on architecture, the edifice itself having been destroyed for the sake of the materials, which were employed to construct the present citadel, upon the same site, in 1636. The other ancient monuments consist of the two temples, originally dedicated one to Rome and Augustus, the other to Diana; and the arch of Sergius. Both temples are placed upon the same line, about 70 feet apart from each other, which interval is now filled up by a range of very ordinary building; but whether they were originally connected, either by a colonnade or otherwise, so as to constitute one general architectural façade, cannot now be determined, although their relative position, and more especially their precise similarity both as to dimensions and design, would seem to favour such supposition. Only one of them however, that of Rome and Augustus, is comparatively entire, the other having been converted into a modern habitation. Although inconsiderable as to size, its external dimensions, including the portico, being no more than 62 feet by 31, it is remarkable for elegance of design and execution; and although it consists of a mere cella with a tetrastyle prostyle attached to it, the latter forms a bold projecting portico, it being diprostyle [Portico], that is, shows two open intercolumns on each flank, which is only one less than those in front. The order is Corinthian, elegant in its proportions and workmanship, with a frieze originally filled up by an inscription beneath the pediment, and decorated along the sides of the building by a rich Arabesque of foliage. One singularity in this example is, that while the shafts of the columns are quite plain, those of the antæ, or pilasters at the angles of the cella, are fluted with five channels on their faces, which is precisely the reverse of the practice of the Greeks; yet this does not seem to have been an architectural caprice, but adopted with the intention of thereby rendering the pilasters more distinct and more important features in the design; whereas insulated columns always arrest the eye, and detach themselves sufficiently from the rest. Much of the elegance of the design arises from the whole structure being raised upon a low unbroken stylobate with deep mouldings, which in front forms the pedestals enclosing the steps leading up to the portico; and it is rather singular that Palladio, who among others has professed to admire this structure, should not have discerned the superior propriety as well as beauty of such stylobate (the height of whose dado, or face, between its upper and lower mouldings, is even less than the diameter of a column), to those proportions which he has himself laid down for pedestals, and which become more offensive when such members are insulated, or else form projecting breaks, instead of a continuous podium, or footing on which the columns are raised.

Even the arch of Sergius, the other monument that remains to be spoken of, although by no means so pure in style and design as the preceding, exhibits lower proportions and greater solidity than usual in the pedestals to the columns. It has been conjectured that this arch, whose date is uncertain, and which now forms the south gate of the city, and is called the Porta Aurata, was intended rather as a private sepulchral structure in honour of the Sergii family, than as a public triumphal arch. The entire structure forms a façade about 28 feet wide by 36 high to the summit of the attic, pierced by a single arch (13 feet wide), on each side of which are two Corinthian columns with the entablature breaking over them, and standing upon a pedestal common to both. Unlike those of the Roman triumphal arches, these columns are not insulated, but each pair consists of engaged columns, the one next the archway being rather more than a semicircle in its plan, and the other, which forms the external angle, being attached to that angle only for one-sixth of its circumference. The archway itself is exceedingly shallow, not more than four feet in depth, consequently a mere opening in a wall, and not a passage through a mass of any depth; and that it was always thus is obvious enough, both from its construction and from there being columns in the other front, though these latter are only rudely sketched out, without having ever been finished. Yet although shallow, the inner part of the arch is very richly decorated, both in the soffit of its archivolt and the space between the impost and the bases of the columns, whose mouldings, as well as those of the pedestals, are continued through the arch.

For architectural delineations and details of these monuments we refer to the fourth volume of Stuart and Revett's 'Athens,' and to Allason's 'Pola' for tastefully executed pictorial representations of them.

POLAND. The comparatively small portion of the once powerful kingdom of the Jagellons, which, under the name of the Kingdom of Poland, forms an integral part of the Russian empire, is nearly of a quadrangular shape (exclusive of a long narrow tract of which we shall speak presently), and is situated between 50° 4′ and 55° 5′ N. lat., and between 17° 30′ and 24° 20′ E. long. The above-mentioned slip extends on the eastern side from 53° 20′ to 55° N. lat.: at the southern part this slip is scarcely 20 miles in breadth, and hardly anywhere exceeds 50 miles. The mean breadth of the southern quadrangular portion, from east to west, is above 200 miles, and its length from north to south about the same. The addition of the slip makes the whole length on the east about 360 miles. Its area, according to Hassel, is 46,000 square miles, but Cannabich and Hörschelmann make it about 50,000, which is the extent of England without Wales. It is bounded on the north by East and West Prussia, on the east and north-east by the Russian provinces of Wilna, Grodno, and Volhynia; on the south by Galicia and the republic of Cracow; and on the west by the Prussian provinces of Silesia and Posen.

Soil and Surface.—Though Poland is generally considered a perfect level, the surface exhibits considerable diversity, and some districts rise many hundred feet higher than others. The lowest and most level portion of the kingdom is situated between 51° 30′ and 52° 30′, where all the rivers run in an eastern or western and south-western direction, and even the Vistula changes its northern into a western course. The northern boundary of Poland runs over the southern declivity of that swell of high ground which must be considered as the southern limit of the plain of the Baltic, and which, beginning west of the western corner of that sea, and between it and the North Sea, extends eastward, at a varying distance from its shores, to the heights of Waldai and the source of the Wolga, into the centre of Russia. The most elevated parts of the surface of this tract are interspersed with numerous lakes, and some districts are literally dotted with them. Its mean elevation seems to vary between 300 and 500 feet above the level of the Baltic. Where it approaches the boundary-line of Poland it has been found to rise about 450 feet. It traverses the narrow and most northern part of Poland between 53° 40′ and 54° 30′. Its northern declivity, towards the Baltic, though gradual, is sufficient to carry off the abundance of water produced by the melting of the snow in spring, and these countries are accordingly in general well drained. Though the soil is sandy, the abundant moisture, by which it is saturated for a great part of the year, imparts to it a moderate degree of fertility, and it produces tolerable crops of rye, buckwheat, barley, and oats. The southern declivity of the swell is still more gentle. The river Bug in its western course is probably more than 300 feet above the sea-level, so that in a distance of more than 50 miles the country hardly descends 150 feet. Hence the rivers in many parts have a sluggish course, not being able to carry off the great supply of water in spring-time, and a considerable portion of the adjacent lowlands is not only inundated at that period, but several large tracts remain under water for the greatest part of the summer, and constitute extensive swamps. Such tracts occur especially along the rivers Bug, Narew, and Bobr; the last-mentioned river falls into the Narew. These low tracts, when drained, might probably be converted into meadows and fields, but some thousands of square miles are at present only used as pasture-ground for a few months, and are overgrown with shrubs and underwood. The more elevated tracts of this region have a sandy soil, but, when carefully cultivated, some parts give a moderate return; in others the soil is barren, and nearly without vegetation, except in spring, when there is a scanty grass. A large portion of this region is covered with woods; the most common tree is pine. Such is the country north of the Bug and the Vistula.

The most southern districts of Poland, the greater part of the provinces of Cracow and Sandomir, and that portion of Lublin which lies between the rivers Vistula and Wieprz, are hilly, and rise in some places to a considerable elevation. The surface of the Vistula above Sandomir is about 600 feet above the sea-level. At no great distance from the banks of the river the country rises with a steep ascent, and continues rising for some distance, until it has attained an elevation of more than 1000 feet, which may be considered the mean height of nearly the whole country between the Vistula and Pilica, with the exception of some tracts along the banks of the first-mentioned river. The highest part of this hilly region seems to traverse it from south-west to north-east, beginning north-west of the town of Cracow, where the small town of Olkusz is built on a hill whose summit is 1240 feet above the sea-level. From this place it runs to Kielce, to the east of which town, near the convent of Swieti Krzyz are two high summits, called Lysagora and Lyscycagora, which attain an elevation of between 1900 and 2100 feet above the sea-level. The country between the Vistula and Wieprz has a less elevation, though it is not less hilly. In the wide valleys of this hilly region the soil, though somewhat sandy, is of excellent quality, and yields good crops of excellent wheat, which is known by the name of Sandomir wheat, and fetches the highest price. On the west of the river Wieprz the country is level and contains only a few low hills. Near 51° 30′ N. lat. is the western extremity of that large region of swamps which forms the boundary between the rivers that run to the Baltic on one side and to the Black Sea on the other, and which extends in a north-north-east direction to the banks of the river Duna, occupying in some places more than a hundred miles in width. A very small portion of it lies west of the river Bug, and is included within Poland, as that river for a large part of its course constitutes the boundary-line between Poland and Russia.

The country which extends from the hilly region to the banks of the rivers Bug and Vistula, where they flow westward, and to the western boundary-line of Poland, may be considered level, as the highest ground, which runs in a south-eastern and north-western direction, hardly rises more than from 200 to 300 feet above the low tracts along the rivers, and the slopes are long and very gentle. The more elevated parts of these higher grounds contain large tracts of sand, nearly without vegetation: in other places they are covered with heath, and here and there some swamps occur, but they are not of great extent. The slopes have a more fertile soil, but even there the crops of rye and oats are scanty. In the vicinity of the rivers fertile tracts are numerous, especially on the low lands along their banks; but in some places these tracts are so low, that the soil is wet nearly all the year round, and they serve only as pasture-ground in the latter part of the summer and the beginning of the autumn. Such swampy tracts occur on the banks of the Vistula, but especially on the river Warta. Large tracts of this region are covered with forests, consisting mostly of coniferæ, especially pines.

Climate.—The range of the temperature is above 100 degrees in the course of the year. The summers are generally very hot, the thermometer rising to above 90°, when the south-eastern wind brings the heated air from the steppes of Astrakhan and other parts of Southern Russia; but these winds are not frequent, nor of long duration, and when succeeded by north-western winds, the thermometer in a few hours sinks 15°. The winters are very cold: the thermometer generally descends to 10° below zero, and sometimes, though not every year, to 15° and even 18°. The country is usually frozen and covered with snow for four or five months: the quantity of snow which falls annually is very considerable; it fertilises the sandy soil and renders it fit for the production of grain and grass. Though the weather in summer is generally steady, there are many rainy days interspersed among the fair weather; these rains invigorate the vegetation when it begins to suffer from the dry weather. Slight fogs occur in spring and autumn.

Rivers and Lakes.—The most considerable rivers are the Niemen and Vistula or Wisla [Niemen; Vistula], which are navigable for large river-barges as far as they drain Poland and flow along its boundary-lines. The number of affluents of the Vistula is considerable. It receives from the east the Wieprz and Bug, which latter river is joined several miles above its mouth by the Narew. The two last-mentioned rivers are navigable to a considerable distance; the Narew to the town of Lomza, and the Bug to Terespol, opposite the Russian town of Brzesc Litewski. From the west the Vistula receives the river Pilica, which is only navigable in the lower part of its course, and to no great distance from its mouth. The river Warta, an affluent of the Oder, begins to be navigable above Kolo, and the Prosna, an affluent of the Warta, above Kalisch. The last-mentioned river forms for the greater part of its course the boundary-line between Poland and Prussia. Lakes are frequent only in some districts. They are most numerous in the north-eastern district, but not of great extent. The largest are those of Augustowa, Duza, Wygri, and Nerza, but they hardly exceed two miles in length. The largest lake, that of Goplo, which is about 10 miles long, lies on the north-western boundary-line. The larger and wider part of it belongs to Prussia.

Productions.—Though Poland is not distinguished by fertility, it produces more grain, hemp, flax, and tobacco than are required for its consumption, and it exports these articles to other countries. Wheat is only abundant in the hilly southern region; the principal species of grain which are cultivated in the other parts of the kingdom are rye, oats, and buckwheat; barley is also raised, but less extensively. Leguminous vegetables are much valued, and their cultivation attended to. Other vegetables and culinary plants are found in the gardens of the nobility, but those of the poor peasant contain only potatoes, cabbages, and carrots. The orchards are much neglected; they consist mostly of cherry-trees, though pears, apples, plums, and walnuts succeed well. Horses and cattle are of inferior size, but rather numerous, and cattle, as well as hides and tallow, are articles of export. Hogs also are numerous, and bacon to a considerable amount is exported. Sheep and goats are less abundant, though some parts of the country are well adapted for sheep-walks; the wool is coarse, and little of it exported.

As a considerable part of the country is still covered with forests, timber constitutes an important article of export. The forests consist of oak, ash, lime-trees, and birch, but chiefly of pine and fir. Great quantities of timber from the large forests of the province of Plock, especially from the great one which surrounds the town of Ostrolenka, are annually floated, by means of the Narew and Bug, to the Vistula and to Danzig. They consist of about 20,000 trunks of pines and fir, and about 300 of oak. In those parts where the lime-trees are numerous the forests swarms with wild bees, and the excellent honey which is obtained from them is sent to the neighbouring countries. Wild animals are numerous, especially wolves, which annually destroy many sheep. Bears and lynxes have become rather rare, as well as the beaver, ermine, and elk; but deer, foxes, martens, polecats, badgers, and weasels are still very common.

Several metals and minerals are abundant in the hilly region. Silver-ore occurs in the province of Cracow, southwest of Kielce, but the mines are only worked on a small scale, and many of them are filled with water. Iron-ore is abundant, and considerable quantities are got out and smelted in the country about Olkusz and Kielce in Cracow, and about Konskie in Sandomir, where it is cast and exported in bars. Copper and lead occur, but do not appear to be worked. Calamine and zinc are more abundant. The largest part of the last-mentioned metal, which is imported into England, is brought from the southern districts of Poland. Very good marble is obtained from some hills near Checzin, south-west of Kielce. Rock-salt is abundant, though less so than in Galicia on the southern side of the Vistula. It is only in modern times that this salt has been worked in two or three places. There is also coal, but it is not much worked.

Divisions.—The kingdom of Poland is divided into eight provinces, which were formerly called waywodships, but by a decree of the emperor of Russia they are now called governments, like the provinces of the Russian empire.

1. Cracow is so called after the antient capital of Poland, which is now a separate independent republic. However, the greater part of the antient waywodship of Cracow is included in the government of Cracow. It lies between 50° 8′ and 51° N. lat., and between 19° and 21° 15′ E. long. It is bounded on the north-west by Kalisch, on the north-north-east by Sandomir, on the south by Galicia, on the south-west by the republic of Cracow, and on the west by Prussian Silesia. Its area, according to Hassel and Hörschelmann, is 4450 square miles· the population in 1831 was 425,000, and may now be 450,000. The Vistula separates it from Galicia: it is traversed by the Nida, and has in it the sources of the Pilica. It is one of the few Polish provinces that are traversed by a branch of the Carpathian mountains. There are some tracts of excellent land, good pasturage, forests, and valuable minerals, especially iron. It is divided into four circles, Kielce, Olkusz, Miechow, and Stobnica. Kielce, the chief town, is situated in a picturesque country surrounded by high mountains; it has an episcopal palace, four churches, a convent of Grey nuns, an ecclesiastical seminary, a lyceum, iron-works, and, in the neighbourhood, mines of iron, lead, copper, coals, and calamine. The population is stated by Hörschelmann (1833) and Cannabich (1836) to be 5000; but Hassel says it was 5000 in 1819, without the garrison. Among the other towns the principal are Pinczow on the Nida, which has 4176 inhabitants. Charles XII. of Sweden defeated the Poles and Saxons near this town in 1702. Chenciny, with a castle on a lofty hill, and lead and silver mines in the vicinity, has 2500 inhabitants. Slawkow on the river Biala has 2050 inhabitants.

2. Sandomir is situated between 50° 25′ and 51° 50′ N. lat., and between 19° 50′ and 22° E. long. It is bounded on the north-west by Masovia, on the north-east by Podlachia, on the east by Lublin, on the south-east by Galicia, on the south-west by Cracow, and on the west by Kalisch. Its area is 5900 square miles, and the population nearly 200,000. The Vistula divides in from Podlachia, Lublin, and Galicia; the Pilica, from Masovia and Kalisch. The face of the country is undulating, and there are here and there some mountains and forests, with tracts of very rich fertile soil. It is divided into the four circles of Sandomir, Opatow, Radom, and Opoczno. Radom, the chief town, on the river Radomka, has a Piarist college, a gymnasium, and 3500 inhabitants. Sandomir, on the Vistula opposite the mouth of the San, has above 3000 inhabitants It is a walled town, with six gates, and an antient castle on a steep rock, which was razed by the Swedes in 1656. There are here a collegium canonicorum, with a church, four convent churches, a synagogue, and a gymnasium. This town is celebrated in ecclesiastical history for the 'Consensus Sandomiriensis,' drawn up in 1570, by the Bohemian, Lutheran, and Calvinist clergy, and in the history of Poland, for the confederation of 1702. Opoczno on the Drzewica has an antient castle and 3500 inhabitants. Opatow on the Opatowka is situated in a fertile and pleasant country, has a cathedral and three other churches, a synagogue, and 2500 inhabitants, chiefly Jews, who carry on a considerable trade, particularly in Hungarian wines. Staszow is a well-built walled town on the Czarna, with a suburb. There are three Roman Catholic churches, a Lutheran Church, and a synagogue. It has above 3000 inhabitants, who have manufactures of cloth, woollens, and stockings.

3. Kalisch, which is the most westerly province of the kingdom, lies between 50° 40′ and 52° 35′ N. lat., and 17° 40′ and 20° E. long. It is bounded on the north and west by the grand-duchy of Posen, on the north-east by Masovia, on the south-east by Sandomir, on the south by Cracow, and on the south-west by Silesia. The area is 6740 square miles, divided into the five circles of Kalisch, Petrikau, Konin, Sieradz, and Wielun. Cannabich says that the population in 1831 was 614,594. This government has mountains in the south, and plains and forests in the north. The soil is in part sandy and swampy, but on the whole not unfruitful. The principal river is the Warta. Kalisch, the capital, one of the handsomest towns in Poland, is situated between two (Hassel says four, and Hörschelmann three) arms of the Prosna, in a marshy valley surrounded with hills. Most of the houses are built of stone, the streets broad and well paved, and some of them planted with trees. The population amounts to 15,000, of whom 2500 are Jews. There are two Roman Catholic parish churches, three hospital churches, one Lutheran church, a cathedral, and six convents. The most remarkable of the churches are the cathedral, dedicated to St. Joseph, and that of St. Nicholas. Among the public institutions are several schools, but the gymnasium and the military school for cadets have been abolished. Woollen cloth and linen are manufactured here, and there are several tanneries. The Swedish general Mardfeld was defeated and taken prisoner near this town by Augustus the Strong, elector of Saxony, on the 29th October, 1706. Petrikau is the seat of a court of appeal; it has seven Roman Catholic churches and a Lutheran church, a gymnasium, a handsome town-hall, and 4276 inhabitants. Konin on the Warta has a great manufactory of woollen cloth, and 3600 inhabitants. Sieradz on the Warta has 2650 inhabitants. Wielun has 3000 inhabitants, who manufacture some woollen cloth. New Czenstochau lies at the foot of the Klarenberg, on which there is a celebrated convent of St. Paul the Hermit, which was formerly fortified and furnished with heavy artillery, but is now dismantled. This convent possesses a miraculous image of the Virgin Mary, to which 40,000 pilgrims annually resort, with whom the inhabitants carry on a profitable trade in images, amulets, crosses, beads, &c. Old Czenstochau is about a mile distant from New Czenstochau, with which it is now connected by a new road, and both together have 5000 inhabitants.

4. Lublin. This government and its capital have been already described. [Lublin.]

5. Plock lies between 52° 15′ and 53° 30′ N. lat., and 18° 45′ and 22° 35′ E. long. On the south it is bounded by the Bug and the Vistula, on the east by the Drewenz; the Narew flows through it. In some parts there are tracts of the finest arable land and meadows, in others extensive forests and marshes. It is bounded on the north and west by Prussia, on the east by Augustowo, and on the south by Podlachia and Masovia. The area is variously stated; some writers making it 7400 square miles, others only 6300 or 6500. It is divided into the six circles of Plock, Pultusk, Lipno, Mlawa, Przasznitz, and Ostrolenka. The population in 1831 was 490,000. Plock is the capital. [Plock.]

Pultusk on the Narew is a bishop's see, and has a palace, a cathedral, three churches, several suppressed monasteries, a synagogue, and a gymnasium. The population is 3376. Wyszogrod on the Vistula has 3500 inhabitants, of whom 1500 are Jews. Modlin at the confluence of the Bug and the Vistula has always been a strong fortress, but since the unsuccessful Polish insurrection of 1829-30, the emperor of Russia has ordered the erection of a new fortress of the first rank, which is not yet completed. The other towns, even the capitals of the circles, are of no great importance.

6. Masovia is situated between 51° 30′ and 52° 55′ N. lat., and 18° and 22° E. long. It is bounded on the north by Plock, on the east and south-east by Podlachia, on the south by Sandomir, on the south-west by Kalisch, and on the north-west by the grand-duchy of Posen. Its area, according to Hassel and Hörschelmann, is 6760, but Cannabich makes it 7500 square miles. It is divided into seven circles, viz. Warsaw, Stanislawow, Sochaczew, Rawa, Lenczyc, Gostynin, and Cujavia. It lies on both sides of the Vistula, which flows through it, and has, on the whole, a rich fertile soil, which is well cultivated in the neighbourhood of the capital, and it also contains extensive forests. Warsaw is the capital. [Warsaw.] (The population of the following towns is given according to Cannabich, 1836. Hörschelmann, in 1833, makes the population much less, in many instances not half as much: he appears to have copied Hassel's work, published in 1821.) Lowicz on the Bzura has 6700 inhabitants, an antient castle, a cathedral, and three other Roman Catholic churches, a gymnasium, four convents, and a seminary for schoolmasters. The inhabitants are partly employed in the manufacture of linen and in bleaching wax. There are two annual horse and cattle fairs, where a great deal of business is done. Sochaczew on the Bzura has 2600 inhabitants; Rawa on the Rawka, 3189 inhabitants; and Lenczyc on the Ner, 2488 inhabitants. Tomaszow, a new manufacturing town at the confluence of the Wolborka and the Pilica, has important manufactures of woollens, cotton, and iron, a considerable trade, and 5000 inhabitants. Alexandrowo, a newly established manufacturing town, with manufactures of woollen cloths, has 3200 inhabitants. Ozockow on the Bzura has also manufactories of woollen cloth, and the population is said to be near 8000. Kutno is a flourishing town, with 4000 inhabitants.

7. Podlachia is situated between 51° 15′ and 52° 40′ N. lat., and 21° 10′ and 23° 40′ E. long. It is bounded on the north by Plock, on the east by Russia, on the south by Lublin, on the south-west by Sandomir, and on the west by Masovia. Its area is variously stated at 4800 and 5300 square miles. This province has the Bug running along the east and western frontiers, on the south-west the Vistula, and on the south the Wieprz; on the south-east there are numerous small lakes, and in the interior extensive marshes and forests; but it is otherwise a good agricultural country, rich in corn, pulse, cattle, honey, and wax; but a considerable portion is still in a very uncultivated state. It is divided into four circles, Siedlec, Lukow, Biala, and Radzyn. Siedlec, the capital, is a regularly built town, with a considerable palace and a beautiful park, several churches, a gymnasium, and 4420 inhabitants. Sokolow, Wingrow, Lukow, and Wlodawa have each above 3000 inhabitants. Kock on the Wieprz has an elegant town-hall, a beautiful church, a palace with grounds in the English style, and 2000 inhabitants. Biala on the Ina has a fine palace and park, and 3586 inhabitants. Miedzerzyce, a well built town on the Ina, has 4340 inhabitants.

8. Augustowo. This government, of which a description has been already given [Augustowo], lies between 52° 40′ and 55° 5′ N. lat., and 21° 25 and 24° 15′ E. long. It is divided into the five circles of Lomza, Augustowo, Seyny, Kalwary, and Mariopol. Suwalky, the capital, was founded about 70 years ago; it has handsome buildings broad regular streets, and 3000 inhabitants. Seyny, situated on a lake, has 2700 inhabitants. The absolution, which is given twice a year, brings together many thousand persons. Lomza on the Narew, in a woody country, has a Piarist college, a gymnasium, and 2300 inhabitants. Szczuczyn is a well-built town, with 3100 inhabitants. Wilkowyszki, in a very fruitful corn country, has 3000 inhabitants. Neustadt (*Nowemiasto*) at the conflux of the Schirwind and the Scheschuppe, surrounded by water on three sides, is on the Prussian frontier; it has much trade, and 3250 inhabitants. Kalwary, situated in a fruitful country, has 5500 inhabitants.

History.—The history of Poland previous to the introduction of Christianity is involved in darkness. The religion and political institutions of its inhabitants were similar to those of the other Slavonic nations, among whom the differences of dialect and manners which now distinguish the various branches of that race were at that time much less marked than they are at present. Christianity was introduced by the duke Mieczyslav, A.D. 965, after his marriage with a Bohemian princess. This event brought the Polish sovereign into close contact with the German empire, of which he became a member, having acknowledged the supremacy of the emperor, not over Poland, but over some provinces which now constitute a part of Lusatia and Silesia. He assisted in that quality at the diet of Quedlinburg, and took part in the wars of the empire. His successor Boleslav Chrobry, or the Brave (A.D. 992-1025), received (A.D. 1000) the royal crown from the emperor Otho III., who came to Poland on a pilgrimage to the shrine of St. Adelbert, and on that occasion declared him king of the Poles and Sclavonians. Thus the Emperor acknowledged his sovereignty over that numerous race, which then occupied all north-eastern Germany between the Baltic and the Elbe, and extended in many parts beyond that river. He also recognised his independence of the empire. Boleslav seems to have had in view the establishment of a Slavonian empire, and his successful wars in Bohemia, Germany, and Russia rendered the accomplishment of such a scheme not improbable. Boleslav not only considerably extended the frontiers of his kingdom, but strengthened it by wise regulations, and particularly by a skilful organization of the military force. The effects of the fortunate reign of Boleslav were marred by that of his son Mieczyslav II., a weak prince, who was entirely governed by his queen Rixa, a niece of the emperor Otho III. But things grew even worse after his death (A.D. 1034), during the minority of his son Casimir I. Rixa, to whom the government was entrusted, rendered herself so unpopular that she was obliged to retire with her son to Germany, and Poland was left to the horrors of anarchy, which lasted several years, until Casimir, being recalled by the principal inhabitants of the country, restored order. He governed the country with great wisdom, and was succeeded (A.D. 1058) by his son Boleslav II., surnamed the Dauntless, who was a skilful soldier and a man of chivalrous character. He restored two monarchs of Hungary, Bela and his son Geysa, as well as the duke of Bohemia, to their respective thrones, from which they had been driven by factions. He defeated the infidel Prussians, and when Tziaslaf, grand-duke of Russia, being expelled from his states, came to implore his assistance, he led him triumphantly back to his capital, Kiew. His residence of about a year in that rich town, which from its constant intercourse with Constantinople enjoyed the luxuries and refinements of Greece, proved unfavourable to his habits. The chroniclers say that his constant success and the great wealth which he acquired in his expeditions to Russia, made him overbearing, dissolute, cruel, and rapacious. He murdered Stanislav Szczepanowski, bishop of Cracow, who had remonstrated against his excesses, and being in consequence excommunicated, his subjects refused to pay him allegiance, and he was obliged to retire from the country, and he died in exile. The notices of some early chroniclers however favour the supposition that the murder of the bishop and its fatal consequences to Boleslav were the result of a factious opposition to his authority, headed by the principal nobles and clergy; and his popularity with the lower classes, which is admitted by the chroniclers, confirms such a supposition.

The vacant throne of Poland was occupied (A.D. 1082) by his brother Vladislav Herman, a weak monarch, whose reign was disturbed by foreign aggression and domestic war. Vladislav's son, Boleslav III., or the Wry-mouth, was a great monarch, who rendered his reign illustrious by many victories, particularly by one gained over the emperor Henry V. But the great glory of his reign was the conversion of the idolatrous Pomeranians. The effects of his fortunate reign were however entirely destroyed by his injudicious partition of the country among his four sons, a custom which was common at that time in many countries. This partition, by destroying the unity of the kingdom and producing internal wars, was productive of much mischief, and arrested the development of the Polish monarchy, which, being the most important Slavonic state, might have become a centre of unity for that race and for a Slavonian empire. Poland recovered from this state of weakness under Vladislav II., surnamed, on account of his short stature, the Cubit, who re-united (A.D. 1306) the dismembered provinces, with the exception of Mazovia, which however remained under the sovereignty of the kings of Poland, and Silesia, whose dukes had become lieges to the king of Bohemia. Vladislav was one of the greatest monarchs that ever governed Poland. He was educated in the school of adversity, having been twice driven from his throne into exile, and it was only on his last restoration that he succeeded in firmly establishing his authority. He exerted himself to settle the disturbed state of the country, to repel foreign aggression, and to curb the licence of the powerful vassals. He was crowned at Cracow, A.D. 1319, and thus restored a solemnity which had fallen into disuse since the death of Boleslav the Wry-mouth. His most formidable enemies were the Lithuanians, and the Teutonic order, whom Conrad, duke of Mazovia, called, about A.D. 1230, from the Holy Land to oppose the Prussian pagans, and granted them a large tract of land with many castles. These warrior monks, who subdued and partly exterminated the half-savage Prussians, soon became the most dangerous neighbours of Poland. Vladislav gained a great victory over them in the battle of Plowce, A.D. 1331. He was then seventy years of age: he died two years afterwards. But the most memorable event of his reign is the first diet of Poland, which he assembled at Chenciny a few months before the battle of Plowce.

The reign of his son Casimir the Great was devoted to the consolidation of the advantages gained by his father. He made great territorial concessions to Bohemia and the Teutonic order for the maintenance of peace, which was necessary to a kingdom that had so long laboured under the evils of war. The improvements which he made were great, and the chroniclers say that he found Poland built of wood and left it built of stone. He indeed rebuilt many ruined cities, and repeopled them with foreign settlers, whom he attracted by the grant of considerable privileges. His chief care was directed to the protection of agriculture: and the nobles, who were no longer permitted to oppress the peasants at their will, gave him the nickname of the Peasant King. The first code of laws was published in Poland by his orders at the assembly of Vislitza, A.D. 1347; and it was during his reign that the Russian principality of Halich was united with Poland. The good will of the inhabitants was secured by the concession of great privileges, and it remained a Polish province till 1772, when it was taken by Austria, and is now known by the name of Galicia. Casimir's great public qualities were unfortunately accompanied with great laxity of morals.

The antient dynasty of Piast,* which reigned in Poland from a date anterior to the introduction of Christianity, ended with Casimir's death, 1370. He was succeeded by his nephew Louis, king of Hungary. This monarch, who was descended from Charles of Anjou, brother to Louis IX. of France, merited the name of Great, which he received from his Hungarian subjects, but he had no right to claim such an appellation from the Poles. Engaged in continual wars with the powers of Italy, and particularly in the affairs of Joan of Naples, who had formerly been married to his brother Andrew, he entirely neglected Poland, which he visited only twice during his reign. But although he paid little attention to that country during his lifetime, he was very anxious to secure the throne to one of his daughters, an object which he accomplished by granting to the nobles, or equestrian order, many privileges, and by a considerable reduction of taxes, A.D. 1371. In consequence of this agreement, his youngest daughter, Hedvige, was proclaimed, after his death, queen of Poland, A.D. 1382, and was crowned at Cracow, being then only 15 years of age. The extraordinary beauty of that princess, which was united to the noblest qualities and the most exalted virtues, have rendered Hedvige's memory an object of national veneration. She married Jagellon, grand-duke of Lithuania, a pagan prince, who was baptised on that occasion, and converted to the Christian religion. [LITHUANIA.] This was a great sacrifice on the part of Hedvige, considering her attachment to William of Austria; to whom she was betrothed from her infant years. But this union effected the conversion of several millions of pagans, and changed a dangerous enemy into a permanent ally, for the accession of Jagellon to the throne of Poland completely united Lithuania with that country. Hedvige died A.D. 1399, but Jagellon, who on his baptism had received the name of Vladislav, continued on the throne till his death, A.D. 1434. His reign was made glorious by the victory of Grunwald, in which the power of the German knights was crushed by the united forces of Poland and Lithuania, though the advantages of this victory were lost by the irresolute character of the king. In Jagellon's reign, the Hussite tenets seem to have spread widely in Poland. The Hussites sent several embassies to Jagellon, and offered to him the throne of Bohemia; but although he might thus have united Bohemia with Poland, he had not resolution enough to accept the offer. He permitted however the princes of his house to assist the Hussites against the Roman Catholics. Jagellon was succeeded by his son Vladislav III., a prince eleven years old. He was scarcely of age when the Hungarians, threatened by the fast-spreading power of the Ottomans, invited him to their throne. The young monarch defeated the Turks (1443) in several battles, and advanced to within six days' march of Adrianople. The Mussulmans sued for peace, and it was concluded on terms most advantageous to the Christians. But this treaty was soon shamefully broken at the instigation of the pope: Cardinal Julian Cesarini absolved the king from his oath, and promised him aid from the Italian powers. The young Vladislav rushed headlong into a new and unjust war; but he was betrayed by the Italians, who, instead of assisting him, transported the Turks across the Hellespont into Europe to oppose him; and he perished at the battle of Varna, in the twenty-first year of his age. The death of the young king plunged Poland into a kind of stupor: the nation could hardly believe the reality of the melancholy news, and numerous reports were spread abroad of his still living as a pilgrim in distant countries. The throne remained vacant till 1445, when all hope of Vladislav's return having vanished, it was offered to his brother Casimir, grand-duke of Lithuania. Casimir was reluctant to accept the crown of Poland, preferring to govern his hereditary subjects the Lithuanians, whose nobles did not at that time enjoy the extensive privileges of the Polish equestrian order, and were less turbulent subjects than the Poles. However, when the states of Poland threatened to transfer their allegiance to a new sovereign, he accepted their offers, and left Lithuania, for which he preserved to the end of his life a strong predilection. The most important event of his reign was the union of the Prussian provinces with Poland. The inhabitants of that rich country, wearied of the oppression of the Teutonic order, declared themselves (1454) subjects of the crown of Poland. A war ensued, which was protracted by the incapacity of the king and by the internal discord which agitated Poland and Lithuania. It was terminated, A.D. 1462, by the peace of Thorn, which gave to Poland a rich and fertile country with a large population. The acquisition of Danzig proved particularly advantageous to the commerce of Poland. It was also under his reign that the representative system of Poland received a definite organization, A.D. 1468. It was determined that each district should elect representatives, and that these representatives should deliberate as a distinct body from the senate: thenceforward a measure became a law when it obtained the sanction of the king, the senate, and the chamber of nuncios, or representatives of the nobles, to which also the deputies of the towns were admitted.

The negligence of Casimir permitted the Tartars to make frequent inroads on the borders, and the Czar of Muscovy seized an extensive tract of Lithuania. Casimir was a great promoter of learning, and he gave a very superior education to his sons, having entrusted them to the care of the celebrated Italian scholar Philip Buonacorsi, better known under the name of Callimachus Experiens, who sought refuge at the court of Poland from the enmity of Pope Paul II. His eldest son, Vladislav, was called to the throne of Bohemia, in 1474, and in 1492 he became king of Hungary. Casimir died in 1492, and was succeeded on the throne of Poland by his second son John Albrecht, and by his third son Alexander in Lithuania.

---

* A traditional or fabulous history of Poland relates that Mieczyslav's ancestor called Piast, who was a common peasant and wheelwright, was elected monarch on account of his great virtues and hospitality about the middle of the ninth century. Hence the name of Piast applied to the dynasty which ended in Poland in 1370, and continued in Silesia till 1675. Piast became afterwards in Poland a legal term applied to a king elected from the natives of the country.

John Albrecht was a warlike prince, but of a careless and indolent disposition. His tutor Callimachus had great influence over him, and advised him to check the overgrown power of the nobles, for which purpose he had drawn up a system of policy to be followed, but the report of these schemes only rendered the opposition of that class the stronger. Having inconsiderately engaged in an expedition against the Wallachians, Albrecht's army was surprised by the enemy and completely defeated. The Turks soon after invaded Poland with a considerable force, but they were almost entirely destroyed by an unusually severe winter. John Albrecht died in 1501, and his brother Alexander, grand-duke of Lithuania, was elected his successor.

Alexander's reign was unfortunate. His marriage with Helena, daughter of Ivan III., grand-duke of Moscow, and Sophia Palæologus, did not prevent his father-in-law from repeatedly invading the frontiers of Lithuania, and taking possession of several castles and districts in that country. The Tartars also committed great devastations in the same country, but they were defeated by his favourite, Prince Glinski, a short time before his death, in 1506. The royal power was much weakened under his reign by the extension of the privileges of the nobles.

After Alexander's death, his youngest brother Sigismund, duke of Troppau in Silesia, was elected king of Poland, having become by inheritance grand-duke of Lithuania. He found the affairs of both countries in a very unfavourable state. The southern provinces of the kingdom were converted into a desert by the repeated inroads of the Tartars, and even some parts of Lithuania had experienced the disastrous effects of their ravages. The czars of Muscovy, who were recently emancipated from their subjection to the Tartars, and had reduced and united with their dominions the principalities of Rezan and Tver, as well as the republics of Novogorod and Pskow, became by these important acquisitions very formidable neighbours to Poland. Though experience proved that the Muscovite armies were inferior to the Polish in courage and military skill, they always surpassed them in numbers. The resources of the Muscovite sovereign were immense; he ruled despotically over many rich and populous provinces; and his mandate was sufficient to call round his standard countless thousands. It was quite the reverse in Poland, where the turbulent nobility frequently and in the most wanton manner opposed the best views of the king, and often resisted his commands with no other view than to assert their own rights, an encroachment upon which they dreaded more than any foreign aggression. It is true that the warriors who generally flocked to the royal standard were the bravest of the brave, but their numbers were few, and though they fought with the utmost gallantry, they were soon tired of the fatigues of the camp. The arrière ban, or general levy of the nobility, called Pospolite Ruszenie, that is, general movement, could only be raised with great difficulty, and it soon returned home. The treasury was empty, and the nobles, unwilling to submit to any taxation, sought to throw all the imposts on the inhabitants of towns, whose number was comparatively small, and on the peasants, who were already crushed by the oppression of the landowners. The crown was in possession of extensive demesnes, but they were generally granted for life to some noble, and the prodigal Alexander had greatly diminished them. All these difficulties were however overcome by the firmness and prudence of Sigismund, and he was much assisted in his task by the treasurer of the crown, Bonar, who succeeded, by his great industry and strict economy, in restoring order to the finances of the country. The revolt of Glinski, a most powerful Lithuanian grandee, who, having been educated at the court of the emperor Maximilian I., acquired great military skill in his campaigns, involved Sigismund in a bloody war with Muscovy. Glinski, who had enjoyed supreme influence under Alexander, created many enemies, who attributed to him treasonable projects, and he was treated with perhaps injudicious harshness by Sigismund. He attacked and murdered his chief enemy, Zabrzezinski, a powerful grandee, and having committed that crime, he declared, together with a great number of adherents, for the Czar of Moscow, who promised to elevate him to the dignity of a sovereign prince of Smolensk. Aided by the traitor, the Muscovites invaded without opposition many provinces of Lithuania, but a brilliant victory obtained by the king in person stopped the progress of the enemy, who were expelled from the Polish frontier, and their own country was invaded. The spirit of insubordination among the army however prevented Sigismund from obtaining any result from his victory, and he was obliged to accept the Czar's proposals of peace. It was concluded by a treaty which left the frontier of the belligerent powers in the same state as it was before the war. The families of Glinski and his adherents were permitted to join them in Muscovy, but many of them were pardoned and restored to their estates and former dignities. [RUSSIA.]

Bohdan, prince of Moldavia and Wallachia, invaded (A.D. 1510) the southern provinces of Poland; he was however soon defeated, and compelled to conclude a treaty, by which he acknowledged himself the vassal of the kings of Poland. This acquisition became afterwards the origin of long and bloody wars with the Ottoman Porte, but an immediate collision with that power was avoided by the prudence of the king.

Pope Julius II. sent an embassy to Sigismund to compliment him on his recent success, and to propose to him to become the head of a league which that pope proposed to form for the expulsion of the Turks from Europe; but this flattering proposition was declined by the Polish monarch, and a brilliant victory over the Tartars, in which 27,000 of those barbarians were slain, secured for a considerable time the tranquillity of the frontiers. Sigismund married Barbara, daughter of Stephen Zapolya, waywode of Transylvania. The emperor Maximilian, who watched with jealousy the influence which Poland exercised over Bohemia and Hungary, and which was increased by Sigismund's marriage, by his intrigues, and particularly by the agency of Glinski, incited the Czar of Muscovy to attack Poland. In 1514 the Muscovites invaded the frontier of Lithuania with an immense force, and took Smolensk. They advanced into Lithuania with an army of 80,000 men, which however, being met by the Lithuanian general, Prince Ostrogski, with a force of 32,000 men, was completely routed at the battle of Orsha. But this brilliant victory was without any result, as the army soon dispersed, without even retaking Smolensk, which remained in the possession of Muscovy at the ensuing peace.

These events induced the emperor Maximilian to seek the friendship of Sigismund, whom he invited to a congress at Vienna in 1515. This meeting produced no advantage to Poland, and the promises given by the emperor on that occasion to interfere with the Teutonic order and the Muscovites on the behalf of Poland, proved entirely delusive. The matrimonial alliance between an Austrian duke and a Jagellonian princess of Bohemia, which was agreed on there, in the course of time placed the crowns of Bohemia and Hungary on the head of the Austrian monarchs, a circumstance which greatly increased their power, and destroyed the influence that Poland had possessed over those countries.

After the death of his first queen, Sigismund married Bona, the daughter of John Galeazzo Sforza, last duke of Milan: She was a most beautiful and accomplished princess, but of a dissolute and abandoned character. She did much mischief by her ambition and intrigues, although she introduced into Poland many Italian refinements, and the Spanish courtesy, which rendered the court of Poland one of the most brilliant and refined in Europe.

The troubles produced by the Reformation of Luther in the Prussian provinces induced Sigismund to repress them by severe measures, which were however taken from political motives, and not from any religious intolerance; for Sigismund on many other occasions showed himself very tolerant towards the doctrines of the Reformation, which under his reign spread over all Poland.* Albert of Brandenburg, grand-master of the Teutonic order, having become a convert to Protestantism, the part of Prussia which was still held by the Order was erected into a secular principality, and Albert of Brandenburg was created hereditary duke of Prussia, and became a liege to the crown of Poland. Thus Poland gave the first example of a diplomatic recognition of a Roman Catholic institution, secularised by the Reformation. Albert's successors continued to recognise the suzeraineté of Poland till the treaty of Velau (1657), by which Prussia was declared an independent dukedom. This was the origin of the dominion of the Brandenburg family over Prussia.

---

* In an answer to Eckius, the celebrated antagonist of Luther, who had sent him Henry VIII.'s book against that reformer, he says that he wishes to be king of goats as well as of sheep.

The dukedom of Mazovia was reunited with Poland after the death of the last prince in 1526; and the Wallachians, who attacked Poland in 1530, were defeated with great loss. The affairs of Wallachia requiring the display of a considerable force, the king ordered the arrière ban of the equestrian order to assemble at Leopol in 1539. According to the account of a contemporary historian (Orichovius), 150,000 militia, splendidly armed, assembled at the royal summons. But this numerous force, instead of marching against the common enemy, raised an outcry against the authority of the king, claiming the redress of certain imaginary wrongs, and the extension of their already overgrown privileges. Thus they separated, without producing any effect whatever, and the memory of this miserable expedition was ridiculed by the nickname of the Chicken War.

Sigismund died in 1548, in the 82nd year of his age, with the character of a wise, just, and magnanimous prince, notwithstanding that in the latter years of his reign he had become unpopular, owing to the misconduct of his queen Bona, to whom he was dotingly attached. He was succeeded by his son Sigismund Augustus, who had been elected and crowned during his lifetime, and was only then ten years old. Before his accession to the throne, and even after the death of his first wife, Elizabeth of Austria, he secretly married Barbara Radzivill, widow of Gastold, palatine of Troki, a most beautiful and accomplished lady, and he declared his marriage publicly a few days after he was proclaimed king. This union, although agreeable to the Lithuanians, was strongly opposed by the Poles, who were afraid that it would give the Radzivills and other Lithuanian families an undue influence in the councils of the king. A violent opposition, influenced by the queen mother, was raised in two diets against the king's marriage, who was required to abandon his wife, and the primate Dzievzgowski promised to distribute on the heads of all the nation the sin of perjury which the king would commit by breaking his marriage oath to Barbara. The firmness of the king quelled that factious opposition, and Barbara was crowned, but she died shortly afterwards, not without strong suspicion of having been poisoned by her mother-in-law Bona Sforza.

At the suggestion of his mother, Sigismund Augustus married Catherine of Austria, the widowed duchess of Mantua. This was a very unfortunate marriage for Poland; it was the cause of Sigismund Augustus dying without issue, of the Jagellonian dynasty becoming extinct, and the throne, which during its existence had been elective only in theory, becoming so in practice.

The most remarkable events of Sigismund Augustus's reign are the acquisition of Livonia, which voluntarily submitted to Poland, in order to save itself from the Muscovite yoke, and the union between Poland and Lithuania, which was effected at the diet of Lublin, 1569. By this arrangement, it was agreed that the deputies and senators of both nations should deliberate in common. The rights of the Polish nobles were extended to those of Lithuania, and the throne of both countries became equally elective; yet the laws, finances, and army remained distinct. This union continued until the final dissolution of Poland.

It was under the reign of Sigismund Augustus that the doctrines of the Reformation acquired a great influence in Poland, particularly among the higher classes: so that there was a time when its complete triumph was expected by the enemies and equally dreaded by the adherents of Rome. Sigismund Augustus was wavering, and his mind seems to have been much unsettled by the conflict of religious opinions. There are however sufficient grounds to believe that he was friendly to a reform of the national church, as his favours were bestowed chiefly on the open and secret promoters of that measure. It is therefore very probable that had he lived longer, this great event would have taken place in Poland.

The interregnum produced by the death of Sigismund Augustus (1572) was dangerous to the peace of the country, particularly as the election of the new king was embarrassed by religious differences. Both the Roman Catholics and the Protestants wished to place upon the throne a candidate of their own persuasion. The following were the candidates for the vacant throne: Ernest, archduke of Austria, brother to the emperor Maximilian II.; Henry of Valois, brother of Charles IX. of France; John III., king of Sweden, son of Gustavus Vasa, who was married to a sister of the late king, and sought the crown of Poland either for himself or for his infant son Sigismund; the Czar of Muscovy, Ivan Vassilovich; and among the natives, John Firley, palatine of Cracow, the chief of the nobles who followed the Reformed or Helvetian confession, aimed at the crown of his country, and had a good chance of success. The hopes of Firley were however destroyed by the jealousy of the Lutheran nobles, headed by the powerful families of Gorka and Zborowski. The diet of convocation, which assembled in January, 1573, adopted a measure which reflects great credit on the prudence of the nation, particularly if we consider the violence of religious parties at that time. It enacted that all the religious sects which at that time divided Poland should enjoy equal rights and privileges; and this enactment, known under the appellation of the Confederation of 1573, became the fundamental law of Poland, and was violated only during the melancholy decline of that country. The extraordinary address of the French ambassador Monluc, bishop of Valence, secured the election of the French prince, notwithstanding the universal feeling against the royal house of France created throughout Poland by the massacre of St. Bartholomew. Monluc gave, in the name of his master, all the guarantees which were required for the political and religious liberties of the nation, and even consented to the demand of the Polish Protestants that favourable conditions should be granted to their co-religionists in France. The solemn embassy which was sent to Paris, in order to announce to the new king his elevation to the throne, gives a favourable idea of the advanced state of civilization at that time in Poland. Thuanus speaks in the highest terms of the great information of the Polish delegates. Henry, after some hesitation, swore to the conditions of election, and went to Poland; but a few months after his arrival, having learned the death of his brother Charles IX., by which he inherited the throne of France as Henry III., he secretly left Cracow (A.D. 1574), and escaped from his new kingdom. He tried however to retain the crown of Poland, and promised to return to that country as soon as the affairs of France would permit him. But as these promises remained for some time unfulfilled, the throne was declared vacant in 1575, and Stephen Battory was elected. He was a very remarkable person, who had risen, by his great merit, from a simple Hungarian noble to the dignity of sovereign prince of Transylvania. This was a most fortunate choice. Battory defeated, in repeated battles, the Muscovites, retook many towns and districts of Lithuania which had been seized by the Muscovites, and invaded their own country. His victorious career was arrested by the intrigues of the Jesuit Possevinus, who induced him to make peace with Muscovy, the Czar of which deceived him by a simulated wish of submitting his church to the supremacy of Rome. Battory was not only a great commander, but a great king, and he established many useful institutions in the country. His death, in 1586, at the moment when he was making great preparations against Muscovy, may be considered as a calamity to Poland, as it destroyed the politic schemes concerted for its future safety, which would probably have been carried into effect. It also opened the field to the quarrels of many powerful nobles, whose factious spirit was restrained by the strong rule of Battory. Several candidates for the vacant throne presented themselves. Fedor Ivanovich, Czar of Moscow, supported by the Lithuanians, was very near being elected. [FEDOR IVANOVICH.]

After the failure of the Czar, two parties divided the electors: one supported Maximilian, archduke of Austria; and the other, headed by Zamoyski, one of the most eminent persons of his time, presented Sigismund Vasa, son of the king of Sweden, and nephew by his mother to Sigismund Augustus. Both candidates were proclaimed kings by their adherents; but Maximilian, being defeated and taken prisoner by Zamoyski, was obliged to resign his claim. The choice of Sigismund III. was unfortunate: bigoted in his attachment to the Roman Catholic religion, in which he had been educated, he was ever ready to sacrifice the interests of his kingdom to those of his church. He thus lost his hereditary dominions, and created a general discontent in Poland by his complete subserviency to the Jesuits and the house of Austria, as well as his tendency towards despotism. A civil war ensued; but the insurgents being defeated, the country was restored to peace. An individual named Demetrius, pretending to be the legitimate heir to the throne of Moscow, who was believed to have been murdered by Godoonoff [GODOONOFF], appeared in Poland. Sigismund, expecting that he would subject the Russian church to the supremacy of Rome, secretly favoured him; and many powerful grandees having espoused his cause, he ascended the throne of Moscow, but was afterwards murdered in a popular riot. An impostor however appeared, who pretended that he had escaped from the massacre, and created great disturbance in Muscovy, where Prince Shooyski was elected Czar instead of the murdered Demetrius. Sigismund, taking advantage of the distracted state of Muscovy, declared war against that country; and the Polish general Zolkiewski, having defeated the Muscovite army and an auxiliary Swedish force, entered Moscow, and concluded a treaty by which Vladislav, eldest son of Sigismund, was elected Czar of Moscow, 1610, on conditions which limited the absolute power that the monarchs of that country hitherto possessed. Shooyski, who had been deposed previous to the entrance of the Poles, was conducted to Poland, where he died in captivity. Zolkiewski made the noblest use of his victory over the Muscovites. Though he entered their country as a conqueror, he restored tranquillity by placing on the throne a Polish prince, and giving to a nation oppressed by the most abject despotism the advantages of a free government, a benefit which was due not to the demands of the Muscovites, who were anxious only to secure the interests of their church, but to the generous and sound policy of the Polish general, who foresaw the dangers which threatened his own country if a prince likely to become its king should possess despotic power in Muscovy. The inhabitants of Muscovy were willing to swear allegiance to their new king; but the accomplishment of that fortunate event, which would have established a constitutional government in Russia, and created a Slavonian empire, and the most powerful state in Europe, was destroyed by the jealousy and incapacity of Sigismund, who, instead of confirming those conditions, delayed his confirmation under various pretences, and in the mean time endeavoured to possess himself of some towns and provinces of Russia. The Muscovites, justly irritated by Sigismund's conduct, rose in arms, and a bloody war ensued, during which the Polish general, ill-supported by the king, maintained himself for a long time against the Muscovites, but was finally obliged to retire. The refusal of the diet to grant the necessary supplies produced insubordination in the army, which was unpaid, and the Russians gained great advantages. Sigismund at last made an effort, and sent his son Vladislav to recover, at the head of an army, the throne which was lost through his father's incapacity, and already occupied by Michael Federovich Romanow, who was elected in 1613. Vladislav penetrated to the walls of the capital; and after an unsuccessful attempt to carry it by storm, occupied a strong position in its vicinity: but the insubordination of the army, which was still badly paid, and several impolitic measures of the king, hastened the conclusion of a truce of fourteen years, by which the Czar Michael Federovich was recognised by Poland, which retained Smolensk with other provinces. This truce was urgent, on account of the increasing hostilities with Turkey, which originated chiefly in the disputed possession of Moldavia, where many powerful Polish grandees, related to Mohila, prince of that country, espoused his part against the Turks, who had deposed him from his dignity. The constant inroads of the Tartars into the Polish territory, and the depredations of the Cossacks, subjects of Poland, committed in the Turkish dominions on the Black Sea, rendered the preservation of peace difficult; but war was rendered inevitable by Sigismund's sending a considerable force to Hungary against Bethlem Gabor, prince of Transylvania, who, with the Bohemian insurgents, was besieging Vienna. This produced a diversion favourable to Austria, but involved Poland in an unnecessary quarrel with Turkey. Zolkiewski, whose expedition against Moscow we have mentioned, having encountered the Turks with a very inferior force, was defeated and killed in 1620. The Tartars ravaged the border provinces; and Sultan Osman marched at the head of an army which is said to have amounted, including the Tartars, to 400,000 men, with the view of conquering Poland, which sent to oppose that overwhelming force only 35,000 Poles and 40,000 Zaporogue Cossacks. The Polish army, under the command of Chodkiewich and Lubomirski, occupied a fortified camp near the banks of the Dniester, and resisted all the attacks of the enemy. Peace was concluded on the 7th October, 1621, on condition that everything should remain in the same state as before the war. In the mean time the Swedes took Riga and many other towns in Livonia, but a truce restored a part of their conquests. War with Sweden was renewed in 1625; but Gustavus Adolphus, unable to obtain any success, proposed, on conditions favourable to Poland, a truce of thirty years, during which the dispute about the succession to the Swedish throne should be settled; but Sigismund, seduced by a delusive promise of assistance from Spain, rejected those offers, and was obliged to conclude, in 1629, a truce of six years, on much less advantageous terms.

Sigismund III. died in 1632, in the sixty-sixth year of his age. His reign of forty-five years was an uninterrupted succession of errors, the immediate effect of which was however in a great degree prevented by the many eminent persons whom Poland produced during his reign; but the seeds of the future calamities of that country were sown by that king. Bigoted in his attachment to the Roman Catholic church, he thought more about the conversion of his opponents than about the interests of his country. Protestantism, which was prevalent in many parts of Poland, was almost entirely destroyed by his efforts; and he effected it not by open oppression, which was rendered impossible by the constitution of the country, but by a cunning system of secret persecution, and by every possible means of seduction.

Several bishops of the Greek church having subscribed to a union with Rome (1598), the opponents of that union, which was supported by the king and the priests, were exposed to much persecution, which scattered the seeds of discontent and future rebellion among the inhabitants of the south-eastern provinces of Poland, and prepared the way for great calamities. Being entirely under the guidance of the Jesuits, the devoted promoters of the interests of Austria, his external policy was constantly subservient to that power, and often at the cost of the interests of Poland. His private character was respectable.

Sigismund's son Vladislav IV. was elected without opposition. He was a virtuous and enlightened prince. Immediately after his coronation he marched against the Muscovites, who had invaded the Polish frontiers, and having defeated them, he entered the frontiers of Muscovy, where he occupied several towns. Peace was concluded in 1634, on advantageous terms to Poland. Soon afterwards the hostilities which had been commenced by the Turks were repelled, and peace was confirmed; the truce with Sweden was also prolonged for twenty-six years. Poland thus enjoyed a long peace during the reign of Vladislav, who died in 1648, at the very moment when a most dangerous rebellion was breaking out.

Although Vladislav was strongly opposed to religious intolerance, his royal authority was insufficient to check the persecution of the followers of the Eastern church, as the long reign of his father had firmly established the influence of the Jesuits in Poland. The consequences of this unfortunate circumstance were soon manifested in the rebellion of the Cossacks of the Ukraine, which originated principally in acts of religious oppression, committed chiefly through the influence of the Jesuits. The rebellion broke out in the last moments of Vladislav, and raged for many years under his brother and successor John Casimir, until Chmielnitzki, the chief of the Cossacks, in 1654, applied for aid to the czar of Muscovy, Alexius, who sent a numerous army to his assistance and another force to attack Lithuania. The situation of Poland was already very critical, but the imprudence of the king made it desperate. Charles Gustavus having ascended the throne of Sweden in consequence of Christina's abdication, John Casimir's ambassador at Stockholm made a protest against his accession to the throne of Sweden, of which his master was the legitimate heir. Charles Gustavus wanted only a pretext for invading Poland, and he was persuaded to do so by Radzieyowski, an influential grandee, who, being unjustly persecuted by the Polish king, became a traitor to his country. The Swedish monarch entered Poland from Pomerania, in 1655, and the adjacent provinces, which were discontented with John Casimir, and influenced by Radzieyowski, joined the enemy, who marched without opposition upon Warsaw. The Polish king fled to Cracow, and thence to Silesia, and Cracow was soon occupied by the Swedes. A Swedish force having simultaneously entered Lithuania, a great number of the inhabitants, menaced by the Muscovites, Cossacks, and Tartars, who ravaged a large part of their country, sought safety by submitting to the protection of the Swedish monarch. A great part of the army, being defeated, was obliged to swear allegiance to Charles Gustavus, who was on the point of becoming king of Poland, his military talents and conciliating policy having gained for him universal respect among the Poles, many of whom believed that their country would regain its power under the rule of such a vigorous sovereign. A deputation accordingly requested him to convoke a diet for his own election, but he proudly answered that he did not require an election, being already master of Poland by the right of conquest. This reply destroyed all his interest, and the Poles began to desert him and return to their king. A confederation was organised in order to restore John Casimir to his throne, and all the nation armed in his defence. The Swedes were attacked, and the czar of Muscovy, jealous of their success, concluded a truce with Poland, and invaded the Swedish province of Livonia. Charles Gustavus maintained himself with great courage and skill. He was joined by Ragotzi, prince of Transylvania, who invaded Poland with 60,000 men, as well as by the forces of the elector of Brandenburg. But these invaders were either destroyed or expelled by the nation, which had unanimously risen against its enemies. The deliverance of the country was principally accomplished by Stephen Czavniecki, one of the bravest and most skilful generals of his time. Denmark having declared war against Sweden, Charles Gustavus was obliged to return to his country. The elector of Brandenburg made peace with Poland and declared war against the Swedes, and Austria sent an auxiliary force to them, which proved of no use, although it was granted on the most onerous terms.

Finally peace was concluded at Oliva, near Danzig, in 1660, by which John Casimir resigned his claims to the Swedish throne, and things were restored to the same state as before the war. This peace gave Poland the opportunity of vigorously repelling the aggressions of Muscovy, with which hostilities had been renewed in 1658, for the Cossacks of the Ukraine, having perceived that the czar of Muscovy was a more dangerous protector than their legitimate monarch the king of Poland, returned to their duty on receiving ample guarantees for their religious and political liberties. The Muscovites were defeated in several battles, and expelled from the country, and their own frontiers were invaded.

This war, which terminated in 1666, destroyed the advantages gained over Muscovy, with which power peace was concluded in 1667, at Andrashov, by which Smolensk and a great part of the Ukraine were left in the hands of the Czar. Both parties were anxious to conclude the peace, being menaced by the Turks, whose aid was called in by Doroshenko, a Cossack chieftain, who intended to withdraw his countrymen from the sovereignty both of Poland and Muscovy, and to place them under the protection of the Ottoman Porte. John Casimir abdicated the throne in 1668, and retired to France, were he died as Abbé de St. Germain, in 1672. He was personally brave, and not without military talent. He had served with distinction in the Imperial armies during the Thirty Years' war.

His disposition was kind and amiable, but easily influenced, owing to which he was governed by his queen and the Jesuits. Before his accession to the throne he had entered the society of the Jesuits, and was afterwards created a cardinal, but the pope released him from his ecclesiastical vows on the death of his brother Vladislav, whose widow he married. His reign was one of the most unfortunate periods of Polish history, and the consequences were equally deplorable. Poland lost Smolensk, and a part of the Ukraine was wrested from her by Moscow. Some important districts were also ceded to the elector of Brandenburg, whose independence of Poland was further recognised by the treaty of Velau, in 1657. The country was depopulated by constant war and pestilence, and emigration to adjoining countries, which was caused by the horrors of war and by religious persecution.

On the death of Casimir there were several candidates for the throne of Poland, but the minor nobility, jealous of the overgrown influence of the magnates, proclaimed as king Michael Prince Wisniowietzki, a young man who had no pretensions to this dignity.

The partisans of the other candidates were carried away by the majority of the electors, and Michael was reluctantly compelled to accept a crown, the burden of which he was not qualified to support. His reign was disturbed by the factious opposition of the primate, who wished to dethrone him, and who was assisted by many powerful grandees, which nearly produced a civil war. The Turks invaded the country with an immense army, and the heroic John Sobieski was unable, notwithstanding prodigies of valour and his great military skill, to arrest their progress. Peace was concluded in 1672, by which Poland ceded to Turkey a part of the Ukraine, and consented to the annual payment of 22,000 ducats. King Michael died in 1673, just at the time when the diet had resolved to break the ignominious peace concluded the preceding year with the Turks; and John Sobieski, who had obtained a brilliant victory over those enemies on the day after the death of Michael, was elected in his stead, notwithstanding the competition of numerous candidates.

Poland somewhat recovered her strength under the rule of that heroic monarch, whose biography requires a separate article. [SOBIESKI.] The reign of his successor, Augustus II. of Saxony (1690-1733), and of Augustus III. (1733-63), are described elsewhere. [Vol. iii., p. 96.] The reign of Augustus III., although tranquil in consequence of the torpor into which the nation had fallen from long exhaustion brought upon it by continual disasters from 1648 till 1717, was fraught with the most eventful consequences. Augustus, who owed his elevation to Russia, fell, chiefly through the instrumentality of his favourite minister, Count Bruhl, entirely under the influence of the cabinet of St. Petersburg, which was anxious to maintain that influence by the weakness of Poland. The Russian court never failed to assure the king that it would never suffer the formation of the smallest confederation or any attempt at innovation which should be directed against the authority of the king or the republic. It meant that it would never permit any improvement of that constitution which kept the country in a state of continual disorganization.

The condition of Poland was indeed wretched at that period. The constantly increasing power of the equestrian order rendered government impossible, and the law was braved with impunity by many powerful nobles, who, although legally on the same footing as the poorest noble, were as powerful as independent sovereigns. A preposterous system of education, which was entirely in the hands of the Jesuits, had so benighted the nation, that it remained satisfied with its condition, imagining itself to be free, while in fact it was governed by foreign influence. This state of things made many patriots strongly feel the necessity of reforming the constitution, which was the cause of all the misfortunes of the nation; but opinions were divided as to the means of attaining this object. The majority of the nobles, headed by the Potockis and Radzivills, wished to maintain all the privileges of their order, and were strongly attached to the Saxon dynasty, which was favourable to their opinions. This Saxon or court party was opposed by the Czartoryskis, who, perceiving that a liberty which was destroying national independence was only an idle name, wished to establish a strong government as the only means of raising the country from its deplorable condition.

Prince Michael Czartoryski and his brother Augustus, who were descended from a collateral branch of the Jagellonian dynasty, possessed at that time immense wealth and great influence. Both of them also possessed great abilities and activity. They undertook to change the republican constitution of Poland into a well-organised monarchy, which, as they justly thought, was the best means of raising Poland from the humiliating position into which she had fallen through her feeble government. For the attainment of that object they had to struggle against the prejudices of the nation and with powerful parties. Keeping their object steadily in view, they encouraged science and literature, elevated to a certain degree of consideration families of little note, and raised others which had been reduced by adverse circumstances. They also sought out and ptronised men of superior talent, and such as by their writings exerted an influence on public opinion, by which means they powerfully contributed to the restoration of literature in Poland.

In this manner they were preparing the nation for a change in the constitution, which however could not actually be effected without force. They endeavoured therefore to gain the favour of the court of St. Petersburg, believing that the venal and incompetent ministry which then governed Russia might be induced to adopt measures useful to Poland. This project was also much encouraged by the English minister in Poland, Sir Hanbury Williams, who endeavoured to counterbalance the interest of France, which supported the republican or Saxon party; and he promised the Czartoryskis the assistance of England and Russia. If the same spirit which presided over the councils of Russia under Elizabeth had continued to govern that country, the project of the Czartoryskis might have been successful; but the accession of Catherine II. entirely changed the state of affairs. The projects of the Czartoryskis, becoming known, created a great sensation even before the death of Augustus III. A Russian force having entered Poland to support the election of Stanislas Poniatowski, the lover of Catherine and a relation of the Czartoryskis, they availed themselves of the assistance of that force, in order to compel the Diet of Convocation to adopt several laws by which the power of dissolving the diet by the *veto* of a single member was considerably limited, the executive authority of the crown strengthened, and the excessive privileges of the nobles were restricted. Their project of abolishing the *veto* altogether was prevented by the foreign ambassadors, and the proposition of electing the king by deputies chosen for that purpose was also defeated. The same diet declared that the confederation continued to exist, which prevented future diets, as long as it was not dissolved by the *veto*. Thus the Czartoryskis accomplished, although by violent and illegal means, a most salutary revolution. The same preponderance which brought about those reforms, effected the election of Poniatowski in 1764, and the diet of his coronation confirmed the reforms to which we have alluded, and introduced other important improvements, particularly in the financial department.

Russia soon perceived how dangerous to its influence in Poland were the reforms which strengthened the government of that country, and it gave its support to the opposition, which was composed of many patriotic individuals, and was too blind to see the advantages of those reforms, being afraid lest they might conduct to a despotic government. The diet of 1766 restored, with some few exceptions, the antient force of the *veto*. The same power, under the pretext of defending the rights of the anti-Roman Catholic confessions, created division all over the country, and finally, in the diet of 1768, in addition to the equitable law of restoring all Christian confessions to equal rights, passed several others of a different character, which tended to weaken the government, and the acceptance of a Russian guarantee declared that state of things immutable.

In order to save the country from foreign influence, a confederation was organised at Bar, a little town in Podolia, by the patriotic bishop of Kamieniec, Adam Krasinski. Ill supported and without any regular troops, it struggled for several years against the forces of Russia, until it fell by exhaustion. The Turks, who had taken up arms in favour of Poland, after having represented in vain to the cabinets of Europe the danger of Russian predominance in Poland, were defeated, and the first partition of Poland, which was planned by Frederic II. of Prussia, took place in 1772. By this partition Poland lost, of the 13,500 square miles (15 to a degree) of its territory, 3925 square miles, which comprehended its best provinces, and were unequally divided between Russia, Prussia, and Austria. The spoliating parties called a diet to sanction this iniquitous transaction, and imposed on the country a permanent council, which deprived the king Poniatowski even of the shadow of authority. This great calamity roused the nation, which now strove to compensate its heavy loss by internal improvements. An excellent system of public education was introduced, and literature was encouraged; industry was re-animated, and every kind of improvement rapidly advanced, through the exertions of many distinguished individuals and of the king himself, who earnestly strove to ameliorate the condition of the country. The chancellor, Andrew Zamoyski, an enlightened and patriotic nobleman, prepared a new code, which removed many antient abuses and partly emancipated the peasants. The code was rejected by the diet of 1780, but an improved public opinion produced in a few years a general wish for a reform in the constitution of the country. The diet which assembled in 1788, having declared itself permanent, continued till 1792, when, on the 2nd of May, it proclaimed a new constitution, which abolished the *veto*, made the throne hereditary in the Saxon family, which was to succeed after the demise of Poniatowski, the reigning king, and introduced some useful regulations. It acknowledged at the same time the necessity of further reforms by enacting that there should be a revision of the constitution after the lapse of twenty years. But a fatal error was committed in neglecting to organise a national force capable of protecting the new constitution from the aggression of its enemies. Russia, who had guaranteed the former state of things in Poland, excited a party composed of a few factious nobles, who, assisted by her troops, formed a confederation at Targovitza, in order to overthrow the new constitution. The king, instead of marching against his enemies, betrayed the cause entrusted to his defence, and, instead of opposing the advance of the Russians, as he had most solemnly promised to do, and ordering a general levy, or arrière ban, he paralysed by his orders all measures of defence, and soon became a party to the infamous confederation of Targovitza. On the other side, the king of Prussia, who had encouraged the patriots to amend the constitution, joined the Russians and invaded Poland. The consequence of all this was a second partition of the Polish territory in 1793, by which Prussia took 1061 square miles (15 to a degree), Russia 4553, and Poland retained 4016. The remaining part of Poland was subjected to every kind of vexation from the confederates of Targovitza, who, encouraged by the presence of Russian troops, persecuted the patriots in every possible manner, and the chief persons among them were obliged to seek refuge abroad. The spirit of patriotism was however not quelled by these circumstances. An extensive conspiracy was organised, and insurrections broke out in several parts of Poland. In 1794 Kosciusko arrived at Cracow, and, having assembled a number of peasants armed with scythes, he defeated a superior number of Russian regular troops. The inhabitants of Warsaw, which was occupied by a strong Russian army, rose against their oppressors, and expelled them after a bloody contest. Vilna did the same. Several individuals were convicted of high treason and executed, but the king was treated with respect. The Poles fought with the utmost bravery, but their courage and patriotism proved unavailing against the overwhelming numbers of Russia and Prussia. Kosciusko was defeated, wounded, and taken prisoner at the battle of Maciejovice, and Praga, the suburb of Warsaw, was carried by storm by Suvaroff, and all the inhabitants were massacred. Warsaw capitulated, and the remainder of Poland was divided in 1795 among Russia, Prussia, and Austria.

Thus Poland was erased from the list of independent states; but the national spirit, which had for centuries withstood the most adverse circumstances and maintained the existence of the state in spite of the dissolving tendency of its constitution, received a new impulse and became more energetic through the severity of the national misfortune. The preservation of nationality against foreign domination was the principal care of those patriots who remained in the country, whilst others raised the national banner in the French armies. On the proposal of General Dombrowski, Polish legions amounting to several thousands of men were formed by the French Directory. This force preserved its national uniform, and fought with great distinction in Italy; its numbers being constantly supplied by fresh arrivals from Poland, as well as by the prisoners of the Austrian troops that were levied in the Polish provinces. These legions were in the pay of the Italian republic, but large sums of money for their support were frequently collected and transmitted from Poland. The extraordinary success of the French armies maintained among the Polish legion a hope that their services in the cause of France would be finally rewarded by the assistance of that power in restoring the independence of their country; but treaties were concluded with the powers which had dismembered Poland, without any regard to the interest of that country. A great number of these troops were sent by the French to St. Domingo, whence few returned. Some of their soldiers went back to their homes after the peace of Luneville, whilst a considerable number continued in the French army. The fate of the dismembered provinces differed according to the governments under which they fell. The Prussian part was well treated in some respects, and the high prices of corn in England gave a great impulse to their agriculture. The state of the peasants was ameliorated, and several improvements were introduced, but these advantages were more than counterbalanced by a decided tendency to establish Germanism on the ruin of everything that was national. The Austrian government was not more favourable to the nationality of its Polish subjects; it introduced some few improvements, such as roads, but it exhausted the Poles by heavy taxes and levies of soldiers in its long wars with France. The Russian part may be considered as having been in some respects the most favoured of all. There were indeed no material improvements, except that for some time agriculture was prosperous owing to the exports of corn to England. But the national language was preserved in all official transactions, and an excellent system of public education, which was carried on in the same language, was introduced by the university of Vilna under the superintendence of its curator Prince Adam Czartoryski, who, supported by the friendship of the emperor Alexander, whose minister he had become, preserved with his sanction the nationality of Poland in the Russian provinces, where the antient laws relating to civil affairs were also retained. Alexander seemed to entertain for some time an idea of restoring Poland and becoming its king.

The success of the French arms against Prussia in 1806 reanimated the hope of the Poles to see their country restored. As soon as the French entered the Polish territory, the inhabitants rose in their favour, and organising themselves into a military force with amazing rapidity, immediately joined the French in combating the enemy. Yet Napoleon, after his success against the Russians, stopped at the banks of the Niemen, and concluded at Tilsit a peace with Russia. The Polish territory which had been taken by Prussia in 1793-5 was erected into a sovereign state under the name of the duchy of Warsaw, with the exception of the province of Bialystok, containing about 180,000 inhabitants, which was given to Russia. A representative constitution was granted, the French code of laws introduced, and the sovereignty declared hereditary in the house of Saxony. The new state, comprehending 1850 square miles (15 to a degree) and 2,200,000 inhabitants, was obliged to maintain an army disproportioned to its population, and of which a considerable part was sent to Spain. In 1809 the Austrians invaded the duchy and occupied Warsaw, which the Polish forces were obliged to evacuate after an unequal combat; but having entered Austrian Poland, their numbers were rapidly swelled, so that their insignificant force soon became a considerable army, and compelled the Austrians to evacuate the duchy of Warsaw, and also a large part of the Polish territory which they held, which increased the duchy of Warsaw to 2800 square miles (15 to a degree) and 3,780,000 inhabitants. The treaty of Vienna arrested the career of the Poles, and only a part of Austrian Poland was united with the duchy of Warsaw. The campaign of 1812 seemed destined to realise the hopes of the Poles, and they made the greatest exertions to contribute to its success. Eighty thousand men marched under Poniatowski and Dombrowski with the French army. But Napoleon damped their hopes at the very beginning by refusing to the Polish deputation to declare at once the restoration of Poland; and he committed a great error in not leaving the Polish army to occupy all the antient territory of Poland, a great part of which was in the occupation of the Russians, whilst the Polish army marched with the French to Moscow.

At the congress of Vienna in 1815, the plenipotentiaries of Great Britain and France, Castlereagh and Talleyrand, were in favour of the restoration of Poland, to which Austria was not averse. But the landing of Napoleon from Elba created interests of a more pressing nature, and the affairs of Poland were arranged in the following manner:—A part of the duchy of Warsaw, containing about a million of inhabitants, was given to Prussia under the title of the duchy of Posen. The salt-mines of Vieliczk and some districts were given to Austria. Cracow with a territory of 490 English square miles, and about 120,000 inhabitants, was erected into a republic; and the remainder was entitled the kingdom of Poland, and united to Russia under one sovereign. The new kingdom received a representative constitution, which guaranteed security of person and property in the strictest sense, the liberty of the press, the responsibility of ministers, the independence of the judges; the use of the national language; and a national military force. The representative body was composed of two chambers, senators and deputies; the former of them were nominated by the king for life, and their number was never to exceed one-half of that of the deputies, which was 138. All the antient Polish provinces which remained under the dominion of the three dismembering powers were promised by the same congress of Vienna a representation and national institution conformable to the nature of the government under which they remained.

Such a liberal constitution granted to a kingdom with 4,000,000 of inhabitants, whose sovereign was monarch over more than 50,000,000 subjects, was a perfect anomaly. It could not be expected that such a constitution should be faithfully maintained; and it was not. The hopes raised by the emperor Alexander, that the Polish provinces incorporated with Russia should be united with the new kingdom, were soon dissipated, and discontent began to spread among all the Polish population. The country, it is true, began to make rapid progress in agriculture, and industry was greatly increased; but the despotic power given to the grand-duke Constantine, brother of the emperor Alexander, who was commander-in-chief of the army, and which manifested itself in the most capricious acts of wanton oppression, irritated the army as well as the inhabitants. Notwithstanding the pledge given at the congress of Vienna to maintain the Polish nationality in the provinces incorporated with Russia, the acts of government evinced a systematic hostility to all that was national. This was particularly the case with the system of public education, which was organised by Prince Adam Czartoryski in a manner favourable to the conservation of the national language and literature. The Russian senator Novossilzoff, to whom the government of the Russo-Polish provinces was entrusted, established a most vexatious system of espionage over the university of Vilna and the schools dependent upon it. Many young men who had formed a society for promoting literature and moral improvement, were imprisoned, and although nothing criminal could be proved against them, they were sent to distant provinces of Russia and forced to enter into the civil service. Many boys, irritated by this system of oppression, had manifested their feelings in violent language at their secret meetings, in which they meditated some childish schemes of resistance; but instead of being visited with the usual school correction, they were sent to serve as common soldiers, and some were condemned to the mines of Siberia. Similar persecution of the students took place at Warsaw, and the system of instruction was continually rendered less efficacious by substituting absurd modes of teaching for sound methods, and by limiting the subjects of instruction. A severe censorship prevented not only the printing of every work of liberal principles, but even the introduction of similar works from abroad.

These causes produced their natural result. Conspiracies began to be organised: the discovery of some increased the severity of the oppression, and the country was infested with spies in the pay of Russia. This only served to irritate the nation. An extensive conspiracy, chiefly among the army and the students, was ready to attempt the overthrow of the Russian government in 1829, when that power was engaged in a war with Turkey, and it was only prevented by some more cautious or timid individuals. The French revolution of July, 1830, which produced a general excitement all over Europe, was not without effect on public opinion in Poland; an insurrection was meditated, and the time was fixed for the spring of 1831. This insurrection would perhaps have never taken place—as the foreign policy of France soon became anti-revolutionary—if the government, having discovered some traces of conspiracy, had not begun to arrest many of the members, a circumstance which forced them to accelerate the time of the insurrection. It took place on the 29th of November, 1830, and was effected by the military school, composed of about 200 young men, who were joined by many students of the university and a few thousands of Polish troops stationed at Warsaw. The Russian troops, which had made some ineffectual attempt to put down the insurrection, took up a position near the town, under the grand-duke Constantine, with whom two regiments of Polish guards remained. Although a few obnoxious individuals were massacred during the insurrection, which they attempted to prevent, it was not sullied by pillage or wanton bloodshed. A provisional government was organised from among the members of the supreme administration, with the addition of some popular persons, and Chlopicki, a veteran general of high military reputation, and universally esteemed for his independent character, was appointed commander-in-chief of the army. The new government acted in the name of the emperor Nicholas as king of Poland, and the grand-duke Constantine remained in his position awaiting the arrival of the army which was summoned to Warsaw from different places. The army having assembled and declared for the Revolution, the grand-duke as its commander, by an order of the day, transferred his authority to the national government, a fact which shows that the Polish army in following that order did not break its oath of allegiance to the emperor of Russia as king of Poland, even in combating against his armies.

The provisional government made an agreement with the grand-duke, by which he was allowed to retire from the country with about 8000 Russian troops and twenty-four cannon. This concession, obtained by Constantine's appeal to the generosity of the Polish nation, was a fatal error; by disarming these troops and retaining the grand-duke as a hostage, not only material advantages might have been gained, but a negotiation with the emperor Nicholas would have been facilitated. Chlopicki proclaimed himself dictator, a measure which was generally approved, as tending to prevent disorder, and as giving strength to the national force; but this extraordinary authority was employed by him only in fruitless negotiations with the Russian emperor. Had he immediately marched on Lithuania, the Russian army stationed in that province, and composed of natives, would immediately have joined the Poles, which would have more than doubled the number of regular troops, besides effecting a general insurrection in that country. Thus while the Poles lost the most precious time in inactivity, the Russians had time to concentrate their troops, and the Polish deputation sent to Petersburg obtained from the emperor no other conditions than absolute submission. Chlopicki, after having brought the country into such a critical position, resigned the dictatorship, and was with great difficulty prevailed upon to promise his assistance to Prince Radzivill, who was nominated commander of the army which was now to oppose the Russians. The diet assembled at Warsaw, having received the answer of the emperor, declared, on the 25th of January, 1831, the throne vacant; organised a national government under the presidency of Prince Adam Czartoryski, and resolved on a vigorous defence. This defence appeared hopeless, as the Poles had only 50,000 men and 136 cannon, besides 14,000 men in the fortresses of Zamosc and Modlin, and dispersed in several parts of the country; while the Russians crossed the frontier with 130,000 men and 396 cannon. This army marched towards Warsaw, whither the Poles were retiring in order to fight under the walls of that city in a position which gave to their small forces a chance of resisting the overwhelming numbers of the enemy. The first combats were favourable to the Poles. General Dwernicki having, on the 15th of February, suddenly attacked and defeated a superior Russian force, with scarcely any loss to himself, several battles took place from the 17th to the 19th of February. An indecisive though murderous battle was fought on the 20th. On the 25th the Russian field-marshal Diebitch concentrated his forces, which were increased by the arrival of fresh resources to 120,000 men and 400 cannon; and he made an effort to crush the Polish army, consisting of about 40,000 men and 100 cannon. A bloody battle ensued, in which the Poles, notwithstanding the inferiority of their force, would have obtained a victory, if some unfortunate circumstances, as well as some faults of the general, had not prevented them from taking advantage of several favourable moments. The Poles lost, from the beginning of the campaign, 11,000 men in killed and wounded: the loss of the Russians is estimated at about 30,000. The Poles retired beyond the Vistula, which separated them from Warsaw, and the armies, except some partisan or small bodies under General Dwernicki, remained inactive, chiefly on account of the difficulty of passing the river at that season. The Polish general-in-chief Skrzynecki, who was invested with the command after the battle of the 25th of February, employed this time in recruiting his forces; but on the 31st of March, when the Russians were making preparations for crossing the Vistula above Warsaw, he attacked and defeated the enemy, of whom 14,000 were taken prisoners. The Russians also lost 10 cannon, and about 4000 in killed. The loss of the Polish troops was insignificant. This advantage however was not followed up as it ought to have been. Meanwhile an insurrection broke out in Lithuania as well as in Volhynia and Podolia. General Dwernicki marched to assist the insurgents of Volhynia, but he was compelled by an overwhelming Russian force to retire into Austrian Poland, where his corps was disarmed and himself kept prisoner; but many officers and soldiers escaped, and joined the Polish army. The Polish commander-in-chief committed many errors, particularly by his unwillingness to strike a decisive blow from a delusive hope that European diplomacy would interfere and settle the question of Poland. After having lost an excellent opportunity of destroying or capturing the Russian guards, he was surprised, and obliged to give battle under very unfavourable circumstances, at Ostrolenka, on the 26th May. The Polish army, much inferior in numbers and in artillery to the Russians, fought in a most disadvantageous position, and was only saved from total defeat by their extraordinary courage and the energy of the commander. The consequences of this battle were deplorable; the troops sustained an enormous loss, particularly of officers; some regiments, which were cut off by the Russians from a communication with the Polish army, were unable to rejoin it, and were obliged to march into Lithuania in order to join the insurgents there, to whom some small assistance was already sent; and the confidence of the army in the ability of the commander-in-chief was shaken, if not entirely destroyed. The troops sent to Lithuania at first obtained great advantages, and would probably have restored the cause of Poland if these prospects had not been ruined by the incapacity of General Gielgud, their commander. A great part was obliged to enter the Prussian territory, where they were disarmed and kept as prisoners; and another part, under General Dembinski, returned to Warsaw, after having effected an almost miraculous retreat of several hundreds of miles, constantly surrounded by the enemy.

Polish affairs assumed a melancholy appearance after the battle of Ostrolenka. The want of ammunition and of every kind of resources was continually more and more felt. This was chiefly caused by the Prussian government, which did not permit the slightest assistance to the Poles to cross the frontier. The Russians, on the contrary, were allowed to have their magazines on the Prussian territory, and always found a friendly asylum whenever they were obliged to retreat there, while the Poles in such cases were invariably disarmed and retained prisoners.

The Russian commander-in-chief Diebitch, died suddenly on the 9th of June, and was succeeded by Paskevich, who had distinguished himself in Asia against the Persians and the Turks. Paskevich resolved to cross the Vistula, and he accomplished his plan by marching near the Prussian frontier, where his magazines were in perfect safety, and where the bridges by which he effected his passage were prepared. The Polish generals committed several faults, by which the Russians escaped from imminent danger, and their army approached Warsaw on the left side of the Vistula. Skrzynecki, who remained under the fatal delusion that the affairs of Poland would be settled by diplomacy, continued to avoid a battle, and the government deprived him of the supreme command. The general excitement produced among the population of Warsaw by the indecisive conduct of those in power, caused a riot on the night of the 15th of August, during which the prisons were forced, and 35 individuals, chiefly spies of the Russian government, and some traitors, together with a few innocent persons, were murdered.

The government, feeling its weakness, resigned its authority, and General Krukowiecki, who is considered to have fomented the troubles of the 15th of August, succeeded through his intrigues in being chosen president of the government. The town being in want of food, a considerable force was detached to collect provisions in the provinces on the right bank of the Vistula, and only 30,000 men were left to defend Warsaw. Provisions were supplied, but the forces sent for them could not reach Warsaw in time, which being attacked on the 6th of Sepember by the Russians, was surrendered to them by Krukowiecki on the 8th. The army, followed by the members of the diet and many leading persons, retired on the right bank of the Vistula, and thence towards the frontiers of Prussia, which they were obliged to enter on the 8th of October, whilst another part of the army was compelled, on the 17th of September, to retire on the Austrian territory. For further particulars the reader may consult *La Guerre de Pologne en* 1831, by M. Brzozowski, the best work which has hitherto been published on this subject.

Thus ended a memorable struggle, which attracted the attention of all Europe, and which, notwithstanding the disproportionate inequality of forces, lasted from February to October, protracted by the desperate courage of the Poles as well as by many faults committed on both sides. The consequences were most deplorable to Poland, and cannot be considered as fortunate to Russia. The emperor Nicholas, instead of adopting a system of clemency, as was generally expected, exercised the utmost severity against the Poles. Many individuals who had taken a part in the insurrection were condemned either to the mines of Siberia or sent to serve as soldiers in the Caucasus and other Asiatic provinces. The constitution was formally abrogated, and another form of government, called the organic statute, introduced. The universities of Vilna and Warsaw, as well as many minor schools, were abolished, and the public libraries and museums were carried away to St. Petersburg and other parts of Russia. An amnesty was proclaimed, but with numerous exceptions, and many soldiers who returned in consequence of that amnesty were compelled to serve in the Russian ranks. Several other measures were adopted tending to destroy the nationality of Poland, and a great number of patriots emigrated to foreign countries.

Sketch of the Polish Constitution before the first dismemberment of Poland.—The king was elective. As soon as he died, the supreme authority was assumed by the primate, who, on that account, was called Interrex. He issued circulars announcing the vacancy of the throne and summoning the diet of convocation. This diet was always confederated, that is, both the chambers, the senate, and the nuncios, or house of commons, deliberated together, and could not be dissolved by the *liberum veto*, and it was on that account also called the general confederation. It issued all the orders necessary for the maintenance of the public tranquillity and safety, and fixed the day for the election of the new king. As the courts of justice acted in the name of the king, their functions were suspended during the interregnum; but special tribunals for criminal cases were formed, and their authority continued till the coronation of the new king, who was crowned by the primate in presence of the diet.

The diet for the election assembled at Vola, in the vicinity of Warsaw, on a spot enclosed by a wall and a ditch: the senate assembled in a temporary building; the nuncios sat in the open air; the nobles, who were assembled from all parts of the kingdom, were encamped at a little distance from the enclosure. After divine service in the cathedral of Warsaw, the diet assembled, a marshal was chosen in the enclosure, and the two chambers were united. The primate then gave his blessing to the senators and nuncios, who joined the nobles of their respective palatinates, who were all on horseback, under the colours of their respective palatinates or provinces. The senators and nuncios proposed the candidates to the nobles of their palatinate or province, and they all voted equally; they collected the votes, and made a report of the result to the marshal of the diet. The primate, mounted on horseback, rode about to the assembled nobles, inquiring from them whether they consented to the election of the successful candidate. The new king was then proclaimed by the grand-marshal of Poland; and either himself or by his plenipotentiary swore to the *pacta conventa*, or constitutional guarantees. The diet then separated.

The diet of coronation assembled at Cracow to witness that solemnity, which terminated the interregnum. The deputies of the towns of Cracow, Warsaw, Vilna, Posen, Danzig, Thorn, and Culm were admitted to the diets of convocation, election, and coronation.

The ordinary diets took place every two years; but in case of necessity, extraordinary diets could be convened. Each diet was preceded by elections, made by royal letters-patent, which contained propositions for the future diet. The nobles or electors assembled for the election in meetings called in Polish *Seyniski*, that is, little diets (in Latin, *Comitiola*); they returned the members, and gave them instructions with respect to the royal propositions, as well as other subjects, which the members were obliged to follow, unless they were empowered to act according to their own views.

The senate and the chamber of nuncios, having assembled at the appointed day in the cathedral church of Warsaw, proceeded, after divine service, with the king to the hall of the senate. Several formalities were observed expressive of respect to the king, who did not speak himself; and the congratulatory address of the chambers was answered by the chancellor, who also read the propositions from the throne, which were only a repetition of what had previously been submitted to the body of electors. The chamber of nuncios assembled under the presidency of the marshal or speaker of the last diet, and began their deliberations by electing a new marshal.

Both chambers formed a secret committee to hear the report of all the measures of the government since the last diet. The *pacta conventa* were read, and each nuncio had a right to make his observations, if he thought that any of their provisions had not been observed. The chambers, having separated, appointed committees to examine the reports of the different departments of government.

The propositions of the king, as well as the motions of the nuncios, were publicly debated. A bill could not be carried except by the unanimous vote of the chamber of nuncios. The bill was read by the secretary of the diet, and the marshal inquired three times whether any member opposed it: if there was no opposition, the bill became a law, and was called *constitutio*. It was afterwards read in the united chambers of the senate and the nuncios, where it was signed. The nuncios were obliged to render an official account to their constituents of their parliamentary conduct, for which meetings were convened.

The king presided in the senate, which acted as a judicial tribunal, at the time when the chamber of nuncios deliberated about the propositions of the king. The senate formed a council of state, and without their consent no royal proposition could be made; consequently a proposition of the king required the approval of the senate, and had only to receive the sanction of the third estate, that is, of the chamber of nuncios. A motion which originated in the chamber of nuncios, or a royal proposition which was amended in the same chamber, was submitted to the king and the senate for their approbation; but the power of the chamber of nuncios at last became so great, that the consent of the king and the senate was never refused. There was always with the king a council of twenty-eight senators, and the whole senate was frequently called together in order to issue ordinances on points for which the fundamental laws of the country did not provide. These were called *senatus consulta*. The senators were appointed by the king for life, unless advanced from a lower rank to a higher, as for instance from a castellan to a palatine. The bishops were also nominated by the king. The senate was composed of two archbishops, fifteen bishops, thirty-three palatines, eighty-five castellans, one starost of Samogitia, who, as well as the castellans of Cracow, Vilna, and Troki, had seats among the palatines. The castellan (not the palatine) of Cracow was the first temporal senator. Forty-nine of the castellans were called minor senators, and had seats on benches, while the others occupied chairs; but their votes were the same as those of other senators. The number of nuncios was 184, besides those of Prussia, whose number was not definite, and who only deliberated when the affairs of their province were concerned.

The nobles, or the equestrian order, were the ruling class in Poland: all legislative power was in their hands, and none who were not born of noble parents could be invested with any civil or military office, or promoted to the higher preferments in the church. No noble could be imprisoned before he was convicted, unless he was taken *in flagrante delicto*. If however he did not appear before the tribunal when cited, he was declared infamous. The house of a noble, as well as his estates, was free from military quarters. He had the power of life and death over the persons on his estates, but this power was abolished in 1764. The house of a noble, as well as of a clergyman, was an asylum. If a foreigner died without issue on an estate belonging to a noble or the clergy, his property devolved to the landowner or the clergy. The nobles were exempted from all taxes. The nobles of antient descent enjoyed all these privileges; but the newly-created nobles, called scartabelli, could not fill offices before the third generation. A noble enjoyed all civil rights when he was possessed of landed property, or was, according to the legal expression, *natus et possessionatus:* the amount of his property might be very small; and the diet of 1768 abolished even that qualification, and established universal suffrage in that class. A noble lost his privileges by carrying on a retail trade, but he recovered them by abandoning the occupation. His privileges were also forfeited by the commission of certain crimes. Each noble was obliged to join on horseback the Pospolite Ruszenie, or arrière ban, with a certain number of followers, determined on the occasion by the king and his council, and proportionate to the extent of his land Those who held crown or ecclesiastical lands on lease were obliged to do the same. A noble who was condemned to imprisonment, was released from his prison during the campaign, but returned to it for the remainder of his term of imprisonment. A noble who did not appear at the time and place fixed, was liable to have his property confiscated, and to lose his honours. In general the martial law which was in force during a campaign was extremely severe. The palatines commanded the arrière bans of their palatinates or provinces, and the castellans those of their districts. There were in each district several permanent officers, who were employed on such occasions.

The king was the head of the state, and had the supreme executive power. He also constituted an estate in the legislative body, which was composed of the king, the senate, and the chamber of nuncios. All judicial and public proceedings were in his name. He had the power of pardon, and the nomination to all dignities and offices, ecclesiastical, civil, and military, with the exception of those which were elective; he granted the starostees, or crown estates. Without the consent of the diet, he could not make laws, impose taxes, declare war, conclude peace, or form any treaty, contract a matrimonial alliance, or leave the country.

The diet of 1775, a continuation of the same which confirmed the first dismemberment of Poland, took away the little authority which the king possessed, by establishing a permanent council of 36 members, consisting of 3 bishops, 11 temporal senators, 4 ministers of state, and 18 nuncios. The king, who was the president of this body, could do nothing without the assent of the council, which was determined by a majority of votes. The ministers of state were 2 grand-marshals, 2 court-marshals, 2 chancellors and 2 vice-chancellors, and 2 treasurers. They were all appointed by the king, who could not dismiss them, as their places were for life, unless they were advanced to a higher rank or resigned voluntarily. The ministers might also be senators. Of all these dignitaries, one was for Poland and one for Lithuania. The grand-marshal was the governor of the royal court, and the first officer of state. He convoked the diets by the order of the king, and during the interregnum by that of the primate. He maintained the public peace during the diets, received foreign ambassadors, proclaimed the new laws, and the sentence of the king in cases of capital punishment. It was also his office to preside over public ceremonies, and to maintain the police in the royal residence. In public solemnities he preceded the king, with a staff, the badge of his dignity. During the absence of the grand-marshal, all those duties devolved upon the court-marshal. When the king resided in Lithuania, the officers of that duchy discharged the same duties.

The chancellor and vice-chancellor differed only in name and precedence; their authority was the same. They gave a legal sanction to the documents issued by the king, by affixing the seals to them. They were also judges in several cases, civil and ecclesiastical, and one of them was always a clergyman. The treasurers presided over the financial departments, and they had a seat in the senate. The other great officers of state, who had not a seat in the senate by virtue of their office, were the grand and field hetmans, or generals of Poland and Lithuania. They kept their offices for life, unless the field-hetman was advanced to the dignity of grand-hetman. This made them independent of the king, and was very injurious to the royal authority; for though appointed by the king, he could not dismiss them. There was also a great number of court dignities for Poland and Lithuania, as great chamberlain, cup-bearers, masters of the stable, &c. Each district had a number of dignitaries with the same names as those of the court but their offices were nominal. These last-mentioned dignitaries were established in those times when the kings in their journeys about the country lived at the expense of the inhabitants, and were served by those local court officers. The starosts (*capitanei*) were of two kinds: starosts with a jurisdiction, capitanei castrenses, who were set over castles and towns, and presided in local courts for criminal and police affairs; and starosts without jurisdiction, who were only holders of starostees, or crown estates, which were granted them on payment of a small annuity.

The confederation was an association formed by the nobles for the defence of their rights. It was generally formed by a few individuals, who met together, and after having composed the act of confederation, which expressed the object that they had in view by forming that association, they issued circulars, by which they invited all the nobles to join their confederation, elected a marshal or chief, and counsellors, or members of the government which they pretended to have a right to exercise, and really did exercise, when their strength was equal to the object. Such confederations frequently added to the disorder of the country, but sometimes they proved the means of its salvation, as was the case with the confederation of Tyszowce in 1656 which freed the country from foreign invasion, and restored John Casimir to his throne. A Rokosh was a general meeting of the armed nobles to represent their grievances and to obtain redress. Such a meeting was legal, when the king, disregarding the admonitions of the senate, persisted in violating the pacta conventa, or the compact between the king and the nation. It was founded on the following clause, which was inserted, for the first time, in the pacta conventa of Henry of Valois (1573): 'Et si quod absit, in aliquibus juramentum meum violavero, nullam mihi inclytæ regni omniumque dominiorum utriusque gentis (Poles and Lithuanians) obedientiam praestare." This clause was better defined by the diets of 1607 and 1609, when it was enacted, in the article 'de non praestanda obedientia,' that an armed opposition to the king might be made only when all constitutional means had been employed in vain, in order to bring him back to his duty, and that otherwise it was treason. Two instances of Rokosh happened in Poland, in 1525 and in 1607.

The courts of justice of the first instance were the territorial courts for civil affairs, composed of elected judges, and castle tribunals for criminal affairs, the judges of which were the starosts (capitanei castrenses) appointed by the king. The courts of appeal, which decided in the last instance, were the tribunals of Poland and Lithuania, instituted by king Stephen Battory. They were composed of deputies, elected annually from the nobles and the clergy, and all matters in which the ecclesiastical came into collision with the temporal courts were decided by these tribunals. The tribunal of Poland sat at Piotrkow for the affairs of the provinces of Greater Poland and Russia, and for the affairs of the province of Little Poland at Lublin; that of Lithuania met at Grodno and Vilna.

The towns were governed by the German municipal law, called the Magdeburg code. This law was introduced at a very early period, and till the reign of Casimir the Great (A.D. 1333-1370) the appeals were carried to Magdeburg. But Casimir abolished the appeal to a foreign tribunal, and established a supreme court of appeal for the towns at Cracow. In later times the affairs of the towns were decided in the last instance by the assessorial tribunal, at the head of which was the chancellor or vice-chancellor: it consisted of the referendarius and other high magistrates, as well as of two senators appointed by the king and four nuncios chosen by the diet.

The referendarial tribunals, which had jurisdiction without appeal, took cognizance of all affairs relating to the royal demesnes. The tribunals of the diet, which were presided over by the king himself, judged in all cases of high treason, and in cases of accusations against ministers, tribunals, and other high authorities.

The constitution of 1791 established the hereditary character of the throne and the abolition of the veto, but it did not sufficiently extend the royal authority, and it may be said that it prepared rather than accomplished great reforms.

Poland was politically divided, previous to its dismemberment, into three provinces, Great Poland, Little Poland, and Lithuania, each of which had sometimes its provincial diets. Great Poland contained the palatinates of Posnania, Kalisch, Sieradz, Lenczyca, Brest of Cujavia, Inovroclav, Plotzk, Mazovia. Little Poland, which, from successive acquisitions from the Russian provinces, was much more extensive than Great Poland, contained the palatinates of Cracow, Sandomir, Kiew, Russian Volhynia, Podolia, Lublin, Belz, Podlachia, Braclav, besides the principalities of Zator, and Osviecim. Lithuania contained the palatinates of

Vilna, Troki Minsk, Brest, Mstislav, Novogrodek, Polotsk, Witepsk, and the principality of Samogitia. The province of Prussia, containing the palatinates of Culm, Marienburg, and Pomerania, had a local legislature, although the deputies of that province took part in the deliberations of the Polish diet in cases where their province was concerned. The bishops, palatines, and castellans of that province belonged to the Polish senate.

POLAND—*Language and Literature*. [SLAVONIAN LANGUAGE AND LITERATURE.]

POLAR BEAR. [BEAR.]

POLAR SEAS is a term generally used to indicate those portions of the ocean which extend from the polar circles to the poles themselves. As the ocean in these parts is generally encumbered by large fields of ice, and the air is frequently loaded with dense and heavy fogs, the navigation is extremely perilous, and was for a long time avoided by the most adventurous seamen. But the experience of the whalers, during the course of two centuries, showed that these seas could be navigated with a certain degree of safety, if the seamen united boldness with care and precaution, and to this experience we owe the great discoveries which have been made in those seas during the last twenty-five years.

In the middle of the last century, geographers, founding their reasoning on some imaginary law of equipoise, were of opinion that a continent of great extent must surround the southern pole; and they supposed that what at present is called Australia was the northern portion of that continent. The question thus raised was to be decided by Captain Cook in his second voyage (1772, 1774). That bold, experienced, and cautious seaman sailed as far as circumstances permitted him along the fields of ice which enclose the southern pole to a distance of more than 20°, but he did not fall in with even an island of any extent, though he frequently passed south of the southern polar circle, and at one place advanced to between 71° and 72° S. lat. Thus the question of a southern continent seemed to be decided. Modern navigators however have discovered several groups of islands in that part of the Southern Polar Sea, where it was supposed that none existed, opposite the southern extremity of America, and the most recent discoveries lead to the conclusion that this part of the ocean contains an island of considerable extent. For an historical account of these discoveries, and a few observations on these countries, see SOUTHERN POLAR COUNTRIES.

That part of the globe which lies within the north polar circle comprehends the most northern portions both of the old and of the new continent; and the term North Polar Sea, or Arctic Ocean, is applied to that part of the sea which divides the northern coasts of Europe and Asia from those of America. Both continents terminate towards the north pole, near 70° N. lat., in America and Europe rather south, and in Asia rather north of that parallel, which consequently may be considered as the general boundary-line of the North Polar Sea. This sea is united to the Pacific by the narrow Strait of Behring, which divides the most north-western part of America from the north-eastern projection of Asia, and in the narrowest part, between East Cape in Asia and Prince of Wales Cape in America, hardly exceeds 18 miles in width. The sea by which it is united to the Atlantic is as wide as the average width of the last-mentioned ocean, and hence the North Polar Sea is frequently considered as the most northern portion of the Atlantic. The eastern entrance of the Fury and Hecla Strait, whose southern shores constitute the most western portion of the northern coast of the American continent (between 69° and 70° N. lat.), are 2212 miles from the coast of Norway, between 69° and 70° N. lat., or not quite 300 miles more than the town of Halifax in Nova Scotia from Valentia in Ireland.

That part of the Arctic Polar Sea where it borders on the Atlantic contains one of the largest archipelagos on the globe. The middle of it is occupied by Greenland, which may be considered as the main land of the archipelago. Its northern parts are buried under enormous masses of eternal ice. On the east of it is the extensive group of islands known under the name of Spitzbergen, the small island of Jan Mayen, and Iceland. On the west of Greenland, and divided from it by Davis's Strait and Baffin's Bay, there is a considerable number of islands of great size, with whose outline we are imperfectly acquainted, and whose number, according to the latest discoveries, has been increased by two new islands. The most southern of these islands approach so near the northern coast of America, as to leave in three places only comparatively narrow but long straits between them and the continent. The most eastern of these straits is that of the Fury and Hecla, which separates Cockburn Island from Melville Peninsula, and was discovered by Captain Parry in 1822. Farther west is Dease's Strait, discovered in 1839, by Dease and Simpson, which extends between the continent and an island, to which no name was given by the discoverers, because they supposed it to constitute the southern coast of an island which Captain James Ross had visited in 1830. This newly discovered strait is 10 miles wide at each extremity, but contracts to three miles in the centre. There is deep water in the middle throughout. Its length seems to be about 25 miles. Farther to the west is a much wider strait, which is likewise nameless, and may be called Simpson Strait, in honour of the companion of Mr. Dease. It separates the island called Victoria Land from the northern coast of America, and was discovered in 1838 by Dease and Simpson. The most western of these straits, called Dolphin and Union Strait, divides from the American continent the island or islands called Wollaston Land, which were discovered in 1826 by Dr. Richardson. West of this strait, or west of 117° W. long., no islands approach the continent of America. If a line is drawn from the western extremity of the Dolphin and Union Strait (117° W. long.) through the pole, and continued towards the south, it cuts 63° E. long., or Cape Nassau, the most northern extremity of the Island of Novaïa Zemlïa. This line, which divides the Artic Polar Sea into two nearly equal parts, may also be considered as the dividing-line between the more and the less navigable portion of that sea. That portion of it which opens towards the Pacific by the Strait of Behring is always so encumbered with immense masses of floating ice, that the boldest navigators have not been able to advance farther north than 70° N. lat., where these floating masses constituted a barrier extending from the coasts of Asia to those of America. No vessels visit this sea for the purpose of taking whales. That portion of the Arctic Polar Sea which opens from the above-mentioned line into the Atlantic is still the principal resort of whalers, and is much more open to navigators. Between Spitzbergen and Greenland vessels have advanced as far as 81° N. lat. British whalers almost every year sail up to the most northern extremity of Baffin's Bay (77° N. lat.), and Parry in his first voyage succeeded in advancing westward as far as 117° W. long., but here he met an impenetrable barrier of ice. On the other side, the Russian navigator Ziwolka, who surveyed the island of Novaïa Zemlïa in 1836, found no difficulty in tracing the western coast to Cape Nassau, and even the eastern to 61° E. long.; but impenetrable masses of ice prevented his advance farther to the east. The very scanty knowledge which we possess respecting those cold regions does not enable us to assign any sufficient reason for this phenomenon; but one of the circumstances which seems to be active in producing this effect is probably the current which sets from south to north through Behring's Strait with great strength, and, passing through the sea, is very perceptible along the eastern coasts of Greenland. It seems however that the whole sea is in motion in the same direction; for Parry, in his fourth and last voyage, when he tried to get to the pole over the ice, was prevented from executing his bold design by the masses of ice which occur north of 81°, on the north of Spitzbergen, being carried by the current southward, so that he lost every day as much as he had gained by moving forwards: in fact he was advancing against the current. If a similar enterprise should ever be again undertaken, the attempt must be made in the opposite direction, where most probably the current would be favourable.

POLARITY signifies, in general, a disposition in a body or in an elementary molecule of a body to place its mathematical axis in some particular direction; frequently also it denotes in a body the existence, either naturally or induced, of two points possessing contrary properties.

If iron-filings be strewed over a mass of natural loadstone, it will be found that there are two points on its surface at which the filings are most abundantly attracted, and where they dispose themselves nearly in the direction of a line imagined to be drawn through the mass. [MAGNETISM.] Then, if the loadstone be cut in the form of a sphere, having this line for a diameter, the symmetrical arrangement of the iron-filings with respect to this line affords an indication that the particles of the loadstone may be symmetrically disposed about the line; and, from an analogy with the axis and poles of the earth, this line is called the axis of the loadstone, and its extremities are called the poles. If the mass of loadstone be cut in the form of a prism, the length of the latter being in the direction of the axis, and if the prism be suspended by its centre of gravity, it will be found to take one particular direction with respect to the horizon and the meridian of the observer. The two extremities of the prism so formed have received the denomination of poles, and the term is now applied to the opposite extremities of any body or molecule, when it assumes or can be brought into a particular direction.

What has been said respecting the properties of a prism formed of the natural loadstone, is true of a magnetised bar of steel [Magnet], and the poles or opposite extremities of either material are found to possess a contrariety of character. One extremity always tends towards the northern part of the horizon only, and the other towards the southern part; and if two such prisms or bars are formed, and suspended by their centres of gravity, on bringing the northern or southern pole of one near the like pole of the other, they exercise upon each other a mutual repulsion; but if either pole of one be brought near the opposite pole of the other, they mutually attract each other.

A piece of natural loadstone, if it could be removed beyond the influence of the magnetic power in the earth, would probably exhibit no signs of that attractive and directive power which we observe in it, the magnetic fluid, or whatever be the cause of the former, being then in equilibrio in the mass; and it may be conceived that the magnetic power in the earth by some means disturbs that equilibrium, forcing the fluid molecules which possess opposite properties, or are in contrary states, towards the opposite extremities of the mass. In magnetising a steel bar it is probable that the natural magnetism is decomposed in a similar manner. Since in magnetised bars the poles of contrary names attract each other, and that the earth may be considered as a body possessing boreal magnetism towards the north, and austral magnetism towards the south, it is evident that the magnetism which exists in the northern extremity or pole of a suspended bar (as a compass needle) must be *austral*, and that which exists in the southern extremity must be *boreal*.

If a cylinder of wood or metal be insulated on a glass stand, and it be then brought near a body which has been electrified by the usual machine, it will be rendered polar; that is, one end will possess the vitreous or positive electricity, and the other the resinous or negative electricity, and near the middle the cylinder will be in a neutral state. These conditions may be rendered evident on electrifying a pith ball, insulated by means of a silk thread, and presenting it to the cylinder, when it will be attracted towards one end and repelled from the other. It appears, from the effect of the cylinder on the electrified ball, that the particles of fluid of the same kind repel each other, and those of unlike kinds attract each other.

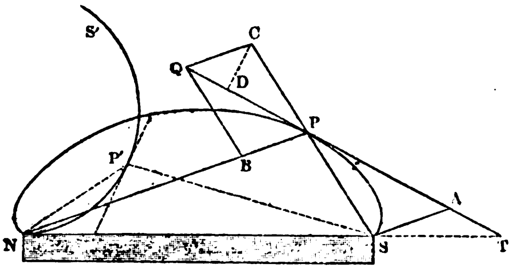
Polarity is also obtained by what is called galvanism, which indeed differs from electricity only in the manner in which a change in the electrical condition of a body is produced; in the latter case friction is employed for this purpose, but in the former it results from the contact of metals susceptible of different degrees of oxidability. In an ordinary battery, the fluid, by chemical action on the zinc, produces a separation of the two kinds of electricity; that which is called positive is carried to the copper plate, and the latter communicates it to the zinc plate with which it is connected. This action is repeated at every pair of plates in the battery; and from the last zinc plate the electricity enters the conducting wire, or that which is employed to connect the opposite extremities of the battery: thus the zinc extremity constitutes the positive pole of the battery. At the same time an opposing current of negative electricity passes from the copper, through the fluid, to the zinc, from thence to the next copper plate, and so on to the last, which is in connection with the conducting wire at that extremity of the battery: this copper end is called the negative pole of the battery.

The attractive power in a magnetised steel bar increases from each extremity to about one-quarter of an inch from thence, where it is the greatest, and it then diminishes gradually towards the centre; this distribution is similar to that of the induced electricity in the insulated cylinder. But experiments show that if a prism of loadstone or a magnetised bar be divided into several parts perpendicularly to its length, each part is a complete magnet, having poles of contrary denominations at its extremities; and this condition is accounted for by Coulomb in the following manner:—He supposes that every molecule of loadstone is a small magnet possessing opposite polarities at its extremities, the axes of all being parallel to or coincident with the magnetic axis of the mass; and that a similar disposition of the molecule is induced in a bar of steel when the magnetic power is communicated to it. The austral polarity of each molecule, while in the mass, is destroyed by the boreal polarity of that which is contiguous to it in the common directions of their axes; but on separating, as above, the parts of the loadstone or magnetised bar, that extremity of each which is farthest from the northern pole of the bar exhibits the austral magnetism appertaining to the like extremities of the molecules; and that extremity which is nearest exhibits boreal magnetism.

A magnetised steel bar, when tried by means of a small compass-needle, is often found to exhibit, at different places in the direction of its length, a change from boreal to austral magnetism, and the contrary. These places are called consecutive poles.

Effects precisely similar to those which have been mentioned are also found to exist in the crystals of tourmaline and Siberian topaz when their electrical properties are developed by heat. The crystals of tourmaline are of a prismatical form with an uneven number of faces, and they are terminated at each extremity by a small pyramid; the polar axes being coincident with what may be called the geometrical axes of the prisms. The crystal being heated to any degree between about 100° and 212° (Fahrenheit), it is found that its extremities possess opposite kinds (positive and negative) of electricity; about the middle there is a space in which the electricity is insensible; and when the crystal is broken across, each fragment exhibits the like phenomena. (Hauy, *Minéralogie*, tom. i.) Boracite, which crystallises in cubes, is found to have four polar axes, the extremities of which possess opposite kinds of electricity when heated. These are nearly in the directions of the four diagonals of the cube.

The intensity of the force, either of attraction or repulsion, exercised by one of the poles of a magnet on any body is inversely proportional to the square of the distance of such body from that pole; and if a very small compass-needle, supported or suspended in the usual way, be brought near a magnetised bar, it must settle, between those opposing forces, in the direction of a tangent to some curve line passing through the two poles of the magnet. This is called the magnetic curve, and the direction of the tangent at any given point may be thus investigated:—



Let N be the north and S the south pole of a magnet; let P be any given point at which the centre of gravity of a small suspended needle may be placed, and join PN, PS. Let the attraction of N on P be expressed by $\frac{1}{PN^2}$ and be represented by PB; also let the repulsion exercised by S on P be expressed by $\frac{1}{PS^2}$ and be represented by PC, in the direction of SP produced. Imagine the parallelogram CB to be formed; then, by mechanics, PQ, its diagonal, will represent the resultant of the forces acting on a particle at P; it will therefore be the direction of the needle and of a tangent to the curve at that point. Let $\angle QPC$ be represented by θ; $\angle QPB$ by θ', and let fall CD perpendicularly on PQ: then by trigonometry, $\frac{\cos.\,\theta}{PS^2}$ is the value of PD, or the equivalent of the force represented by PC when reduced to the direction PQ; and $\frac{\cos.\ \theta'}{PN^2}$ is the value of QD, or of the force PB (=QC) when reduced to the same direction. The sum of these, or $\frac{\cos.\ \theta}{PS^2} + \frac{\cos.\ \theta'}{PN^2}$, is the value of PQ, and represents the whole force of the magnet on the point P in the direction of that line: hence,

$$PQ^2 = \frac{\cos.^2\ \theta}{PS^4} + \frac{\cos.^2\ \theta'}{PN^4} + 2\frac{\cos.\ \theta \cos.\ \theta'}{PS^2.\ PN^2}.$$

But, by geometry, $PQ^2 = PC^2 - QC^2 + 2PQ.\ QD$; which, by substitution becomes $\frac{1}{PS^4} - \frac{1}{PN^4} + 2\left(\frac{\cos.\ \theta}{PS^2} + \frac{\cos.\ \theta'}{PN^2}\right) \frac{\cos.\ \theta'}{PN^2}$. Equating these values of PQ^2 and leaving out terms which destroy each other, we have $\frac{1}{PS^4} - \frac{\cos.^2\ \theta}{PS^4} = \frac{1}{PN^4} - \frac{\cos.^2\ \theta'}{PN}$; whence $\frac{\sin.\ \theta}{PS^2} = \frac{\sin.\ \theta'}{PN^2}$, and $\sin.\ \theta : \sin.\ \theta' :: PS^2 : PN^2$.

Now, produce QP till it meets NS, produced, if necessary, in T; and draw SA parallel to NP: then, by trigonometry,
SA : PS : : sin. APS : sin. PAS : : sin. QPS : sin. QPN; that is,

$$SA : PS :: \sin.\ \theta : \sin.\ \theta';\ \text{hence}$$

$SA : PS :: PS^2 : PN^2$, which being compounded with the identical proportion PS : PN : : PS : PN gives

$$SA : PN :: PS^3 : PN^3.$$

But SA being parallel to PN, SA : PN : : ST : NT; therefore $ST : NT :: PS^3 : PN^3$.

Thus the ratio of ST to NT is known; and, consequently the position of the tangent PT, from the given position of P. If the poles N and S are unlike, as above supposed, the curves are of the kind called convergent, as NPS; but if the poles are similar, the curves will be divergent, as NP′S′.

An analogy has long been known to subsist between electricity, galvanism, and magnetism, in respect of the power of imparting polarity to bodies and of modifying each other's effects. Coulomb found, in 1802, that needles of gold, silver, copper, lead, and even wood, when about one-third of an inch long and one-fiftieth of an inch thick, if suspended between the opposite poles of two strong magnets, presently arranged themselves in lines joining those poles. (Biot, *Traité de Physique*, tom. iii.) Sir Humphry Davy, Mr. Faraday, and other philosophers, both in this country and abroad, succeeded in exciting magnetism in steel bars by the galvanic battery; and gold needles galvanised have been found to acquire polarity, and to be subject, with respect to the horizon and the meridian, to a certain variation and dip, different however from those of a steel bar when magnetised.

A small piece of steel-wire may be magnetised, or made to acquire polarity in a short time, by merely placing it perpendicularly across the conducting wire of a galvanic battery in action; and it will be found that one end of the steel attracts either the north or south pole of a compass-needle according as it is placed above or below the conducting-wire. But the method employed by M. Ampère to magnetise needles was to twist a wire spirally about a cylinder, and to place the needle in a glass tube within the spiral; then, connecting the two extremities of the spiral with the poles of a galvanic battery, the needle was found, after a few minutes, to be strongly magnetised. When the spiral was formed from the right hand downwards, to the left, above the axis, that extremity of the needle which was nearest to the negative end of the battery pointed towards the north, and the extremity nearest to the positive end towards the south; and when the spiral was formed in the contrary direction, the extremity of the needle which was nearest to the positive end of the battery pointed towards the north. By this method a great intensity of magnetic power is produced; the action of the wire upon the needle being repeated as many times as there are revolutions of the spiral about the latter.

In 1820, M. Oersted observed that if a magnetic needle, suspended as usual, be placed under and near the wire connecting the opposite poles of a galvanic battery, the pole of the needle which is nearest to the negative end of the battery declines westward; and if the needle be placed above the wire, that pole declines eastward. The amount of the deviation depends on the distance of the wire from the needle; and when the distance is about three-quarters of an inch, it amounts to about 45°. When the wire is in the same horizontal plane as the needle, the latter suffers no deviation; but, if on the western side of the needle, the pole of the latter, which is nearest to the negative end of the battery, becomes depressed; and if on the eastern side, that pole becomes elevated. The hypothesis proposed by Oersted and Ampère to account for the action of the wire on the needle is, that a current passes along the conducting wire of a galvanic battery from each pole towards the middle; and that these currents, on meeting, turn each other from their rectilinear directions, so that both are compelled to move spirally in opposite directions round the wire. In thus revolving, they act upon the magnetic particles in the needle, or upon the electric currents supposed to circulate about them, producing changes in the positions of those particles, and thus turning the needle from its place. It was a discovery of Biot, that if a perpendicular line were let fall from any point in a magnetised needle to the conducting wire of a battery, the electric force acting on that point is perpendicular to the line and to the axis of the wire; and if the magnetic particles in the needle were free to move under the impulses communicated to them by the electrical currents about the wire, it is supposed that those particles would arrange themselves so as to place their axes in planes coincident with those of the electric currents, and at right angles to the lines let fall from them perpendicularly on that axis. Such were found by Mr. Barlow to be the dispositions assumed by very small magnetised needles when placed in any positions near the conducting wire; the effects of terrestrial magnetism on them being neutralised by means of magnets properly placed for the purpose.

POLARIZATION OF LIGHT is the effect of an attraction exercised by the particles of what are called *doubly refracting* crystals, or of certain reflecting surfaces, upon the particles of light when these pass through the former, or are incident upon the latter at a particular angle. By those attractions the particles of light, considered as not perfectly spherical, are supposed to suffer such changes of disposition that their axes, or their homologous faces, become parallel to one another, or are directed towards the same part of space. This supposition may be admitted, if we consider the particles of light to be transmitted in rectilinear directions from a luminous body; but if we adopt the undulatory hypothesis, a different explanation must be given. In this case, understanding that the vibrations of the ethereal particles in waves of common light may take place in any manner (suppose in the direction in which the wave is advancing, in some direction oblique to that line, or even in directions which are continually varying); the polarization of that element may be stated to consist in such a resolution of the attracting forces exerted upon light by the molecules of the refracting medium or the reflecting surface, in consequence of their particular dispositions, that the vibrations of the particles of light in the direction of the wave's motion vanishing, the resulting vibrations shall take place in a plane perpendicular to that direction, and in lines parallel to one another. A plane perpendicular to all the lines of vibrations is called the plane of polarization.

Huygens was the first who discovered that when a pencil of light falls upon a prism of Iceland spar in any direction except one, it divides into two pencils in passing through it, and presents to the eye a double image of the object from whence the pencil proceeds; he observed also that one of these images was formed by a refraction of the usual kind, that is, having the usual relation between the sines of the angles of incidence and of refraction, and that the other was not so formed, the ratio of the sines not being constant. He called the pencil by which the first image was formed the *ordinarily* refracted ray; and the other the *extraordinarily* refracted ray. Iceland-spar crystallizes in the form of a rhomboid, and Huygens discovered that if the rhomboid is cut so as to form a plane face perpendicular to the axis (a line making equal angles with the three natural faces or planes of cleavage which form one of the obtuse solid angles)—when the pencil of incident light falls on the rhomboid in the direction of this line, it is wholly refracted in that direction, or the ordinary and extraordinary pencils are coincident. In all other positions the pencils are separated; and the angle between them is a maximum when the incident pencil is perpendicular to a plane cut in any position parallel to the axis. When the incident ray is perpendicular to one of the natural faces of the rhomboid, the angle between the two refracted pencils is equal to 6° 40′, and the line joining the images of the object is nearly in the direction of the shorter diagonal of that face.

Huygens also observed, that if the two pencils formed by one which had been made to fall perpendicularly on a natural face of the rhomboid of Iceland spar are suffered to fall upon a second rhomboid placed so that two like natural faces are parallel to or in contact with each other, each of the first refracted pencils is not divided into two, but in passing through the second rhomboid the *ordinarily* refracted pencil suffers only the ordinary refraction, and the *extraordinarily* refracted pencil suffers only the extraordinary refraction. The same thing takes place when, keeping the same faces in contact, one of the rhomboids is turned about through an angle of 180°, so that the ends are reversed. But the same faces being in contact, when one of the rhomboids is turned either way so as to be at right angles to its first position, each pencil, after passing through the first rhomboid, though it suffers only one refraction in the second, changes its character; that which was before *ordinarily* refracted, now becomes *extraordinarily* refracted, and the other becomes *ordinarily* refracted. In all other positions of the rhomboids each of the two pencils is divided into two in passing through the second; the angle between them varying according to the position of the rhomboids with respect to each other.

The circumstances just mentioned show that the ordinary and extraordinary pencils, in passing through one rhomboid, acquire properties of a like kind with respect to two planes passing through the incident pencil at right angles to one another. If one of these planes pass through the axis of the crystal perpendicularly to one of the natural faces, the properties of the ordinary pencil have the same relation to this plane which those of the extraordinary pencil have to a plane passing through the incident pencil perpendicularly to the same plane: or the particles in the ordinary refracted wave always vibrate perpendicularly to the first, which is called the principal plane, and those in the extraordinary refracted wave always vibrate perpendicularly to the second plane. Therefore it is said that the ordinary pencil is polarized in the principal plane of the crystal, and the extraordinary pencil is polarized in a plane perpendicular to the principal plane.

Double refraction is now known to take place in many crystals; and the line in which the ordinary and extraordinary pencils coincide is called the optical axis, or the axis of double refraction. In Iceland spar it nearly coincides with the shorter diagonal of the rhomboid; but in quartz, tourmaline, and other prismatic crystals it coincides with the geometrical axis of the prism. All these are called uni-axal crystals, though every line which can be drawn in the prismatic crystals parallel to the geometrical axis has the property of uniting in one the ordinary and extraordinary pencils.

Some crystals have two and others three axes of double refraction; and Dr. Brewster, who discovered the fact (in 1816), found that the two images were united in the bi-axal crystals, in the directions of both axes.

If the light of a candle be viewed through a thin and polished plate of tourmaline, whose surfaces are parallel to the geometrical axis of the prism, which, by crystallization the body forms, the plate being held perpendicularly to a line drawn from the candle to the eye, that light will appear equally distinct in every position of the plate. But, the plate being fixed, if the pencil from the candle be made to pass through a second plate parallel to the former, and the second plate be turned round in its own plane, the image of the candle will vary in brightness according to the relative positions of the two plates. If the axes of the plates (lines in them parallel to the geometrical axes of the prisms from which they are cut) are parallel to each other, the brightness of the image is a maximum, and if the axis of one is at right angles to that of the other, the image vanishes; the light diminishing in intensity from the former position of the axes to the latter in each quadrant of the revolution of the second plate.

In 1810 M. Malus, a Colonel of Engineers in the French service, communicated to the Institute of France the discovery that when a pencil of light is reflected at some particular angle from the surfaces of transparent bodies, solid or fluid, and also from certain opaque bodies, as black marble and ebony, it becomes polarized, like the pencils which are transmitted through a doubly refracting crystal. Thus, if a pencil fall upon the surface of unsilvered plate-glass at an angle of about 54° 35′ with a perpendicular to that surface, and the reflected ray be transmitted through a rhomboid of Iceland spar, whether the principal section of the rhomboid be parallel to the plane of reflection (plane of the incident and reflected rays), or whether it be perpendicular to it, the pencil suffers no *extraordinary* refraction; but in all other positions the pencil is divided into two in passing through the rhomboid, as if it had previously been refracted in a rhomboid of the spar. It may be observed that the polarization of the light takes place simultaneously at the upper and under surfaces of the glass plate: the pencil of light being incident on the former surface at the angle above mentioned, though it is obvious that the angle of incidence at which the pencil falls on the latter, is less than that at which the pencil fell, before refraction, on the upper surface.

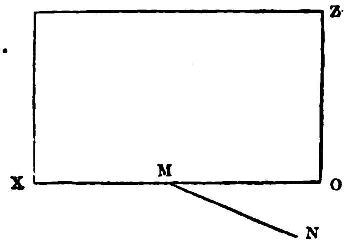
When the reflecting surface is water, the light is found to be polarized when the angle of incidence is 52° 45′; and it is found that when the tangent of the angle of incidence is equal to the refractive index (the quotient which arises on dividing the natural sine of the angle of incidence by that of the angle of refraction) of the glass or transparent medium from whose surface the light is reflected, the whole of the reflected light is polarized; just as the ordinary pencil produced by the first rhomboid of Iceland spar would be if its principal plane were parallel to the plane of reflection, and common light had passed through it instead of being reflected from the medium.

In the undulatory theory of Optics the phenomena of the reflection and refraction of common light may be satisfactorily explained by supposing a wave to diverge symmetrically every way about the point at which an agitation of the ethereal medium has taken place, the transparent substance in which a pencil is refracted being supposed to be uniformly elastic; and, consequently, it may be admitted that in common light the undulations are of a spherical form having the agitated point as a centre. But it is evident that if the molecules of the medium through which the vibrations of light are transmitted are not uniformly elastic, the particles of light will move with different velocities in different directions; and thus the waves will not be spherical.

It was an hypothesis of Huyghens that the extraordinary refraction in Iceland spar arose from a propagation of the light composing the pencil in spheroidal waves; but to M. Fresnel is due the investigation of a general equation for the form of a wave, or, as it is called, the surface of elasticity in that medium. The research is founded on the supposition that the arrangement of the particles in the crystal is such that, while the attractions exercised by those particles on any one of the luminiferous particles in a wave have for their resultant a force which is not in general coincident with the direction of the vibrations of the latter in the wave, there may yet be three lines of direction at right angles to one another, and having a common point of intersection, in each of which, if a particle be displaced by its vibration in the wave, the resultant of the attractions shall be in the same line, and shall act in a direction opposite to that of the displacement. For a demonstration of this property in an elastic medium see the article Light in the 'Encyclopædia Metropolitana,' sect. 998, &c.

Now imagine three rectangular co-ordinate axes OX, OY, OZ to exist in the crystal, and suppose the crystal to be cut in the form of a rectangular parallelopiped, having one of its axes, as OZ, coincident with the axis of the crystal (supposed to be uni-axal). Let OX, OZ coincide with the plane of the paper, and let the constitution of the crystal be such that the attractive forces of its particles upon the luminiferous æther among them are equal in directions parallel to OX and OY, but different in directions parallel to OZ.

Fig. 1.



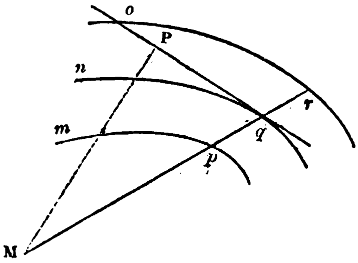
M. Fresnel considers that, whatever be the law of the attractions of the particles of crystal, the attraction exercised upon a displaced particle of light must be some function of that displacement; and that, in the direction of the co-ordinate axes, it may be represented by $a.X$, $a.Y$, and $b.Z$ respectively; where a and b (forces of elasticity) are constants depending on the positions of OX, OY, and OZ, with respect to the particles of the crystal; the force in OY being equal to that in OX, as above, by the nature of the crystal; also X, Y, and Z are the components, in the directions of the co-ordinate axes, of a displacement or extent of the vibration of a particle in any direction from O. Let this displacement be represented by D, and let the line of direction in which the particle vibrates from O make with OX, OY, OZ the angles α, β, γ respectively; then $X = D \cos. \alpha$, $Y = D \cos. \beta$, $Z = D \cos. \gamma$; and, if the attractions in the co-ordinate axes be reduced to one in the line of vibration drawn from O, the whole attraction in that direction becomes $a D \cos.^2 \alpha + a D \cos.^2 \beta + b D \cos.^2 \gamma$. M. Fresnel then imagines a surface of elasticity (curve surface of a wave) to be constructed so that the variable radius from O may be proportional to the square root of the last expression; and, representing that radius by R, we have $R^2 = a D \cos.^2 \alpha + a D \cos.^2 \beta + b D \cos.^2 \gamma$. But, when R coincides with OX, we have $\alpha = 0$, and both β and γ are right angles; consequently, in that case $R^2 = a D$, which represent by A^2. Again, when R coincides with OY, we have $\beta = 0$, and both α and γ are right angles; consequently then, also, $R^2 = a D$ or A^2. Lastly, when R coincides with OZ, $\gamma = 0$ and $R^2 = b D$, which represent by B^2. Thus A, A, B may represent the three rectangular co-ordinate axes of the surface of elasticity; and the wave is therefore of a spheroidal form.

Now, let the plane front of an incident wave, perpendicular to the paper, fall upon the plane of the axes OX, OY, making with it an angle equal to OMN (which represent by θ), and cutting it in a line passing through M perpendicular to the paper. Then, considering only those vibrations of the particles of luminiferous ether in the front of the wave which take place in lines parallel to MN, and in lines parallel to that drawn through M perpendicular to the paper, that is parallel to OY; the latter vibrations are those which are immediately acted on in the same lines but in opposite directions by the force of elasticity in OY; that is, by the force $a Y$, which holds the place of $a D \cos.^2 \beta$, or of A^2 in the value of R^2 (since β is now $= 0$). The vibrations in lines parallel to MN must be resolved into vibrations parallel to OX and OZ; which, by mechanics, may be done on multiplying them by $\cos. \theta$ and $\sin. \theta$ respectively: so that, if D' be the displacement of a particle in MN, we have $D' \cos. \theta$ for the displacement in OX, and $D' \sin. \theta$ for that in OZ; and these being reduced to the direction MN become $D' \cos.^2 \theta$, and $D' \sin.^2 \theta$ respectively, which hold the places of $a D \cos.^2 \alpha$, $b D \cos.^2 \gamma$, in the value of R^2, since, when R is in the plane XZ, γ is the complement of α. Therefore the whole force of attraction on a vibrating particle in the direction MN may be represented by $A^2 \cos.^2 \theta + B^2 \cos.^2 \theta$, while the force in the direction perpendicular to MN and to the paper may be represented by A^2. But the radii of the surface of elasticity, by the hypothesis of M. Fresnel, are represented by the square roots of these terms; therefore A represents the radius in the direction parallel to OY on either side of M, and $\sqrt{\{A^2 \cos.^2 \theta + B^2 \sin.^2 \theta\}}$ represents that in MN on either side of the same point.

By the theory of undulations these represent the velocities with which two waves of light are propagated within the crystal in directions perpendicular to their fronts; and, being unequal, it follows that there will be two series of waves diverging from M, their directions depending on their velocities. The velocity represented by A being constant, this branch wave, whatever be the direction of the incident pencil, is of a spherical form and follows the law of ordinary refraction; that is, the sines of the angles of incidence and refraction bear to each other a constant ratio; the other velocity, depending on θ, differs according to the direction of that pencil; and hence arises the extraordinarily refracted pencil. Since each of these waves is formed by vibrations in directions parallel to one line, the ordinary wave by vibrations parallel to OY, and the other by vibrations parallel to MN, the light in each of the two refracted pencils is that which is called polarized light; and the lines of vibration OY and MN being perpendicular to one another, it follows that the planes of polarization for the ordinary and extraordinary pencils are also perpendicular to one another.

If M be the centre of the wave of extraordinary refraction, the fronts pm, qn, ro, &c., at any successive intervals of time will be similar, and the tangents at p, q, r, &c., in any line drawn from M, will be parallel to one another; then, if a line be let fall from M perpendicularly to any tangent qP, the distance MP will always be proportional to $\sqrt{\{A^2 \cos.^2 \theta + B^2 \sin.^2 \theta\}}$, where θ is the angle MqP, or NMO in the former figure. But by the nature of the ellipse, if A be the semi-transverse, and B the semi-conjugate axis, any diameter, as one parallel to Pq, making an angle equal to θ with the semi-transverse axis, is equal to

Fig. 2.



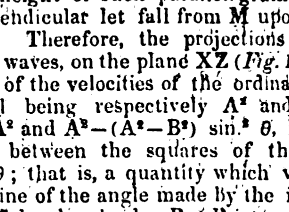
$$\frac{A.B}{\sqrt{\{A^2 \cos.^2 \theta + B^2 \sin.^2 \theta\}}};$$ and, since the parallelogram formed on two conjugate diameters is equal to A.B, it follows that, in an ellipse, $\sqrt{\{A^2 \cos.^2 \theta + B^2 \sin.^2 \theta\}}$ is equal to the perpendicular height of such parallelogram; that is, it is equal to a perpendicular let fall from M upon the tangent Pq, as above. Therefore, the projections of the plane surfaces of the waves, on the plane XZ (*Fig.* 1) are ellipses.

The squares of the velocities of the ordinary and extraordinary pencil being respectively A^2 and $A^2 \cos.^2 \theta + B^2 \sin.^2 \theta$, or A^2 and $A^2 - (A^2 - B^2) \sin.^2 \theta$, it follows that the difference between the squares of the velocities is $(A^2 - B^2) \sin.^2 \theta$; that is, a quantity which varies with the square of the sine of the angle made by the incident pencil with the axis of the rhomboid. But B is greater than A in Iceland spar, tourmaline, beryl, and many other crystals, in which case $A^2 - B^2$ is negative; and hence the crystals of this class have been called negative. When A is greater than B, as in quartz, ice, &c., the crystals are called positive. In the former case the velocity of the extraordinarily refracted pencil is greater than that of the ordinary pencil; or the refractive index for the ordinary pencil is greater than that for the extraordinary pencil. And, in the latter case, the velocity of the extraordinary pencil is less than that of the ordinary pencil; or the index of refraction for the ordinary, is less than that for the extraordinary pencil.

In polarized light the vibrations of particles in the direction of the wave's motion are insensible.

The rule discovered by Huyghens for finding the velocity of the extraordinary pencil is as follows:—In the negative crystals (Iceland spar, &c.) let AB be the axis in which the double refraction vanishes, and let CD be drawn at right angles to that axis; then, if a plane perpendicular to the paper pass through this line, the double refraction in such plane will be a maximum. Let m be the index of refraction for the ordinary, m' the index for the extraordinary pencil, and imagine a spheroid having its axes AB, CD inversely proportional to those indexes; that is, let AB $\left(= \frac{1}{m}\right)$ be the smallest, and CD $\left(= \frac{1}{m'}\right)$ be the greatest. Then the variable radii, On, &c. of the spheroid will represent the velocities of the extraordinary pencil when light is incident upon a sphere of crystal in the directions of such radii.

Fig. 3.



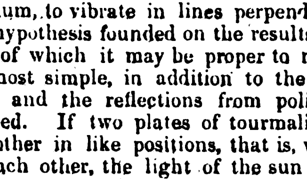
M. Biot, who discovered the class of positive crystals (in which m' is greater than m), showed that when AB is made the longer, and CD the shorter axis of the spheroid, the radii On still represent the velocities of the extraordinary pencil; and M. Fresnel has given the following more general rule: Imagine any ellipsoid, whose axes A, B, and C are reciprocals of the refractive indexes in those directions, to be cut by a plane passing through the centre; the lengths of the greatest and least radii in the section will be the lengths of the radii of the ordinary and extraordinary waves, and consequently the velocities with which those waves are propagated in the crystal when light is incident in a direction perpendicular to that section.

In crystals possessing three unequal axes of elasticity it is proved that the ellipsoid of elasticity admits of two circular sections, which are formed by diametral planes passing through the mean axis of the ellipsoid, and that these sections are equally inclined to the two other axes. The normals to these sections are the directions of no double refraction, or the optic axes of the crystal. And both Fresnel and Dr. Young have shown that if unity be divided by the squares of the two semi-axes of a diametral section of such ellipsoid, the difference of the quotients will vary with the product of the sines of the angles which the perpendicular to this section makes with the two normals to the circular sections of the ellipsoid.

That the polarization of light consists in its particles being made, by the attractions of the molecules of the polarizing medium, to vibrate in lines perpendicular to some plane, is an hypothesis founded on the results of numerous experiments, of which it may be proper to mention one or two of the most simple, in addition to the refractions in Iceland spar and the reflections from polished surfaces already noticed. If two plates of tourmaline are placed one on the other in like positions, that is, with their axes parallel to each other, the light of the sun or of a candle will be readily transmitted through them; and if, while the plates are in contact, one be turned round in its own plane, the light will gradually diminish till the axes of the plates are at right angles to each other, when none will pass through. Now these circumstances indicate that the luminiferous æther can pass freely through such plates only when the vibrations of its particles in them are performed in lines parallel or perpendicular to the axis of the plate; and that the cause of the light being arrested at the second plate, when its axis is perpendicular to that of the first, is the impossibility of the particles, while so vibrating in passing out of that first plate, finding a passage between the molecules of the other in that position of its axis. Hence it may reasonably be concluded that, by the attractions of the crystal molecules, the vibrations of the particles in the waves of incident light were brought to the directions above supposed.

Again, if two pieces of unsilvered plate-glass be placed so as to send the light of the clouds from C to the eye at E, after reflection at A and B, the angles of incidence and reflection at both being equal to the polarizing angle (54° 35′); then the pencil being polarised at A, if the glass B be so situated that the pencil BE is in the plane of reflection CAB (supposed to be perpendicular to both glasses and to coincide with the plane of the paper), the greatest quantity of light is reflected from that glass: but, the glass A remaining undisturbed, if the other be turned about the point B so that its plane, now oblique to the paper, may make always the same angle with the line AB; in proportion as BE, by such revolution of the glass, deviates from the plane of reflection CAB, the light reflected from the glass will diminish, and it will finally vanish or be absorbed when BE becomes perpendicular to the plane CAB. The loss of the light in the position last mentioned may be considered as an evidence that the vibrations of the particles in the polarized pencil AB, BE are, after reflection from A, rendered perpendicular to one plane, as CABE. Now the reflected pencil BE remains polarized till it vanishes entirely, which is when it is brought into a plane perpendicular to CAB; at this time the vibrations at B become perpendicular to their former direction, or parallel to the plane CAB; in which state the constitution of the reflecting surface is such as to absorb or disperse the light of that pencil. It appears therefore that light which has been polarized in one plane cannot produce polarized light in a plane at right angles to the former.

Fig. 4.



By a partially polarized pencil is meant one which, having been reflected once at an angle greater or less than the polarizing angle, when seen through a tourmaline plate capable of revolving in its own plane, or when received at the polarizing angle on another reflecting surface which, like the glass B above, may revolve upon the first reflected pencil without altering the inclination of the latter to it; the pencil thus seen through the tourmaline, or twice reflected, never vanishes entirely in consequence of such revolution of B, but merely undergoes variations of brightness and passes through several states of greatest and least intensity. It must be observed also that all the different colour-making rays of light are not polarized by reflection at the same angle; and hence it is that white light is not completely polarized when reflected from any transparent medium having a high dispersive power.

Rock crystal, which has the power of polarizing light, is also found to have the power of depolarizing it, or of reducing it to its ordinary state, when the polarized light is transmitted through it in one particular direction. This discovery was made by Dr. Brewster, who also found that the like property existed in Iceland spar, topaz, chrysolite, and several other minerals. Gum arabic, horn, and tortoise-shell were found to depolarize light in every position. Dr. Brewster also ascertained that, if a prism of Iceland spar were placed, either in a horizontal or a vertical position, upon a plate of mica or topaz, the plane of the latter being vertical, the light polarized by the mica suffered no change in passing through the spar; but when the spar was placed on the mica, at an angle of 45°, with a vertical or horizontal line, the polarized light was completely depolarized. Dr. Brewster therefore gave to these diagonal lines the name of *depolarizing* axes; and to those in vertical and horizontal directions, the name of *neutral* axes. When the Iceland spar was inclined to the vertical neutral axis of a plate of mica or topaz, in a plane perpendicular to that plate, at such an angle that the polarized light fell on it at an angle of 45°, the image, which was before invisible, reappeared; that is, the light became depolarized. This effect did not take place when the spar was similarly inclined to the plate in a plane passing through the horizonal neutral axis of the mica; but, on making the trial with the depolarizing axis, it was found that each of these last was accompanied by an oblique neutral axis. (Brewster on *New Philosophical Instruments*, book iv., ch. 4.)

The phenomena first observed by M. Arago in 1811, and called by him circular polarization, consist in the changes of colour undergone by the two images formed when a polarized ray is made to pass at right angles through a plate of rock-crystal cut perpendicularly to the axis of double refraction, and when those images are examined by a doubly refracting prism. On turning this prism half round, the *extraordinary* image, which at first was red, became successively orange, yellow, green, and violet; and on continuing the revolution of the prism, the tints recurred in the same order. The hypothesis proposed by the discoverer, in order to account for this effect, is that the several coloured rays, on emerging from the rock-crystal, are polarized in different planes. Again, if between the glasses at A and B (*fig.* 4) there be interposed a plate which possesses the property of double refraction, the image reflected from A appears generally bright, but at times covered by dark rays, and sometimes by complicated rings richly coloured; the arrangement depending on the direction of the pencils to some fixed lines in the interposed plate, as the latter is inclined. Now the light being polarized by A, the sets of waves enter the crystal with different velocities, and their union in passing through it produces a light not polarized, or not in the same planes as before; therefore they again became capable of being reflected from B. But since the positions of the two planes of polarization, as well as the difference in the velocities of the pencils, depend upon the directions of the paths through the crystal; the nature of the light produced by the union of the two emergent pencils, and consequently its intensity, will vary with the direction in which it enters the eye after reflection from B. Thus variously coloured spots and curves will be seen. (See Airy's *Math. Tracts*, *Optics*, Art. 144, &c.)

This branch of optics has been extended by Brewster, Biot, Fresnel, Young, Sir J. Herschel, and others; but it may be sufficient in this place to have indicated it.

Professor Forbes of Edinburgh has succeeded in polarizing radiant heat, both by reflection and refraction; employing, for the purpose of measuring the intensities, an instrument of such delicacy as to be capable of indicating an increment of temperature equal to about $\frac{1}{1500}$ of a degree of Fahrenheit's thermometer. The Professor has also depolarized heat; and since depolarization is a consequence of double refraction, it follows that the existence of a doubly refractive property in heat is thus demonstrated. [Undulatory Theory of Light.]

POLDERS. [Flanders Agriculture.]

POLE, POLAR. The word πόλος as applied to a point means a turning or hinge point, and was applied to the points at the extremity of the axis of the celestial sphere in the antient astronomy. Hence, on the hypothesis of the earth's rotation, it comes to mean the extremities of the axis on which the earth turns. From this primary meaning all the various uses of the word pole have been derived. For example, when it was found that the magnet did not always point to the north pole, but to another point, it was natural to call that other point the *magnetic* pole. Previously to this use of the word, it had already taken a wider signification, as follows:—On looking at the position of the equator with respect to the poles, it is obvious that if the equator, or circle of equal day and night, should be changed, the axis must also be changed, and the poles of rotation. Hence any great circle of the sphere is said to have its poles, meaning those points which would become poles of rotation if that circle became the equator. [Sphere.]

A term seldom passes through several significations, however nearly related, without at last becoming generic in the widest sense. The word pole is now used to denote any point which is of so striking a character as to require a distinct name. In physics the word is naturalised in magnetism, electricity, and optics; insomuch that any tendency towards a particular point, or even towards a particular direction, is termed polarity. In geometry, the only definition which can now be given of this term is, that it means any point which it is wanted to mean. Thus a point considered as the origin of Co-ordinates is called the pole; and when distances measured from the origin are among the co-ordinates, they are called polar. Again, it is a well known property of the conic sections, that if all possible chords be drawn through any one given point, and a pair of tangents be drawn from the extremities of each chord, the intersections of all the pairs will lie in one straight line; the point through which the chords are drawn is called the pole of that straight line.

POLE STAR. [Ursa Minor.]

POLE. [Perch.]

POLE, REGINALD, the celebrated Cardinal, was born in A.D. 1500, the same year which gave birth to the emperor Charles V. He was of very illustrious descent on the side of his mother, who was the daughter of George, duke of Clarence, brother to King Edward IV., and cousin-german to Elizabeth, queen of Henry VII. and mother of Henry VIII. He was a younger son, and received an education such as was given to those who were destined to high stations in the church, being placed when a child in the Carthusian monastery at Shene, from whence he was removed to Magdalen College, Oxford, where he had the benefit of the instruction of the celebrated Linacre. As early as 1515, he was made B.A., admitted into deacon's orders, and, when only nineteen, was made dean of Wimborne and dean of Exeter.

About 1520 he went abroad to pursue his studies in an Italian university, visiting Padua for that purpose. He returned to England in 1525, when he was received by the king in a manner befitting his rank and eminent attainments. But the gaieties of the court of Henry VIII. had fewer charms for him than the opportunities for seclusion and study which were afforded by the monastery at Shene, to which he retired. Times were however approaching when it was impossible for a man like Pole to be a mere spectator from the silent hold of a Carthusian monastery, nor could he think it right to be a mere spectator, mild and gentle, humane and pious as he was.

When the king had resolved on divorcing his queen and acting in defiance of ecclesiastical authority, Pole presented a strenuous opposition, and wrote his famous treatise *Pro Unitate Ecclesiastica*. This was a great disappointment to the king, who withdrew his pension, deprived him of his preferments, and procured that he should be attainted in parliament. The king had now entered on that bloody course in which he persevered for the remainder of his life. There is little doubt that Pole would have shared the same fate which befel More and Fisher, had he not withdrawn himself from England and the reach of the king. As it was, his elder brother was put to death, and his mother, the old Countess of Salisbury, was executed, both on the poorest and weakest pretences.

During the remainder of the reign, and through the whole reign of Edward VI., Pole lived abroad. In proportion as he was hated by the king, he was cherished by the pope, by whom he was made a cardinal, employed on several important embassies, and was in fact a principal adviser touching all matters which effected the spiritual affairs of the realm of England, and touching the Reformation generally. On the death of pope Paul III. in 1549, he narrowly missed being elected to the popedom. Failing in this, he retired to a convent near Verona, where he continued till the accession of Mary to the English throne, when an attempt was made to re-unite the English nation to the great body of the Western church.

He reappeared in his native country at the very beginning of the reign, coming as legate from the Roman see, with full power to absolve the nation, and receive it again into the bosom of the Catholic church. Parliament supplicated the queen that this re-union might take place, and the re-union was effected. Then began the cruel measures for the extirpation of heresy and heretics, which have made the reign of Mary so infamous in the English annals. How far Cardinal Pole was implicated in the guilt of those needless and unjustifiable severities, is one of the points in his life on which different opinions will be entertained by those who study with attention the history of that period. It is certain that he had great influence in the councils of that reign, and that he accepted the archbishopric of Canterbury when Cranmer was put to death. At the same time, the apparent rectitude of his conduct and the general mildness of his disposition seem to forbid us to suppose that he could be any party to the dreadful severities of that period.

Besides the high dignity of primate, he was made chancellor of both the universities, which he visited by his commissioners. If any man could have done it, he would have effected the entire reversal of the measures of the Reformation in England, had the life of the queen been prolonged: but her reign was short; she died in 1558, and, by a singular coincidence, Pole himself died about sixteen hours after her.

Those who wish to enter at large into the history of this distinguished person, and to see what may be said on both sides, in respect to his character and conduct in those ambiguous times, may consult his Life, written by Mr. Philips, and the Review of the Life, by Dr. Gloster Ridley. His portrait by Raffaelle, well known by the engravings of it, gives a very lively idea of his personal appearance.

POLECAT. [Weasels.]

POLEMARCH. [Archon.]

PO'LEMO (Πολέμων), the name of several Greek writers, of whom the most important are:—

1. Polemo, the philosopher, the son of Philostratus, who succeeded Xenocrates as the head of the Old Academy about B.C. 315. (Diog. Laert., iv. 16.) He died in B.C. 270, and was succeeded by Crates. (Clinton's *Fast. Hell.*, vol. ii., p. 367.)

Polemo wrote several works (Diog. Laert., iv. 20), which are referred to by Cicero (*Acad. Quæst.*, ii. 42), but none of them have come down to us. Cicero says that Polemo did not differ much from Aristotle. (*De Orat.*, iii. 18.) Zeno and Arcesilas were his disciples. (Cic., *Acad. Quæst.*, i. 9.)

2. Polemo, the sophist, who was born at Laodicea, and was one of the most celebrated teachers of rhetoric in the beginning of the second century of the Christian æra. He

was highly esteemed by Hadrian and Antoninus Pius. He taught at Smyrna, and conferred great benefits upon the town. He died in his fifty-sixth year, and is said to have been buried alive at his own request, because he was unable to endure the pain which he suffered from attacks of the gout.

The Life of Polemo has been written by Philostratus, who mentions several of his works. These however are all lost, with the exception of two funeral orations (ἐπιτάφιοι λόγοι), supposed to have been spoken in honour of Cynægirus and Callimachus, who fell in the battle of Marathon. These orations were first published by Stephanus, 1567, and afterwards by Poussines, 1637, Toulouse. The most recent and the best edition is by Orellius, Leipzig, 1819, 8vo.

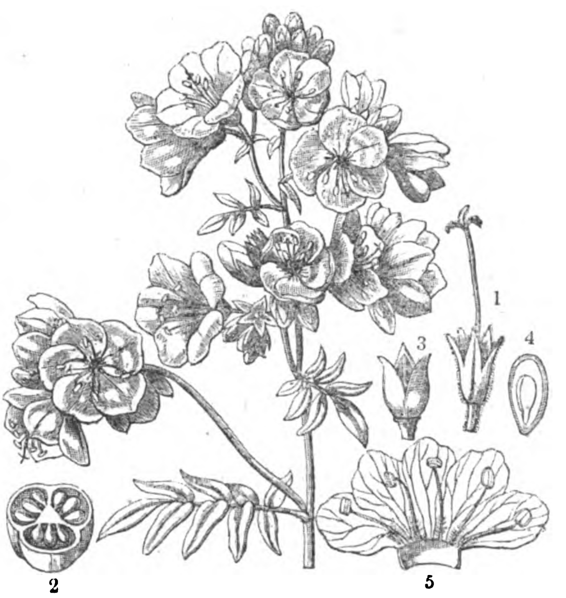
(Fabricii *Bibliotheca Græca*, ed. Harles, vol. vi., p. 2; Philostratus, *Life of Polemo.*)

3. POLEMO, surnamed PERIEGETES (ὁ περιηγητής, Strabo, ix., p. 396), was a native of Samos or Sicyon (Athen., vi., p. 234, d), and was made a citizen of Athens. (Suidas, *Polemo.*) He lived about B.C. 200. A list of his works, which amount to twenty-six in number, and are principally on geographical and historical subjects, is given by Clinton, in the third volume of his 'Fasti Hellenici,' p. 514. None of these have come down to us entire, but the fragments which are extant have been published under the following title:—'Polemonis Periegetæ Fragmenta collegit, digessit, Notis auxit L. Preller. Acc. de Polemonis Vita et Scriptis et de Historia atque arte Periegetarum Commentationes,' Lips., 1838, 8vo.

PO'LEMO (Πολέμων), the author of a work on physiognomy which is still extant, of whose life no particulars are known. According to some writers, he was an Athenian, but Sylburgius (in *Præfat. ad Aristot.*, vol. vi.) and Fabricius (*Bibl. Gr.*, vol. ii., p. 170) consider his style to be too incorrect for a native of that city. From some expressions used by Polemo (for instance, the word εἰδωλόθυτος, lib. i., cap. 6, p. 197), it seems probable that he was a Christian. As to his date, it is only known that he must have lived before the time of Origen, who quotes him (*Cont. Cels.*, lib. i., p. 26). His work (which appears to have suffered much from the ignorance of transcribers) is divided into two books. In the first, which contains twenty-three chapters, after proving the utility of physiognomy, he lays down the general principles of the science; he speaks of the shape of the head, of the colour of the hair, of the forehead, the eyes, the ears, the nose, the manner of breathing, the sound of the voice, &c: in the second book, which consists of twenty-seven chapters, he goes on to apply the principles he had before laid down, and describes in a few words the characters of the courageous man, the timid, the impudent, the passionate, the talkative, &c. The greater part of his observations are very ridiculous, but several of them have been borrowed by J. B. Porta and other more recent writers on the subject of physiognomy. His work was first published by Camillus Peruscus, with Ælian's 'Varia Historia' and other works, Græce, Romæ, 1545, 4to. A Latin translation by Nicolas Petreius was published with Meletius 'De Naturâ Hominis' and other works, Venet., 1552, 4to. There is also an edition of the Greek text by Franc. Montecucli, Mutin., 1611, 4to.; and it is inserted by Sylburgius in the sixth vol. of his edition of Aristotle's works, Francof., 1587, 4to. The best edition is that by J. F. Franzius, who has inserted it in his 'Scriptores Physiognomiæ Veteres,' Altenb., 1780, 8vo., Gr. and Lat., and has added a learned preface and notes.

PO'LEMO. [PONTUS.]

POLEMONIA'CEÆ, a natural order of monopetalous Exogens, with a trifid stigma, three-celled fruit, and seeds attached to an axile placenta, the embryo lying in the midst of albumen. They are allied to Convolvulaceæ, from which their calyx, æstivation, placentation, seeds, and three-celled fruit distinguish them; and also to the Echial alliance, from which their placentation, undivided capsular, not nucamentaceous fruit, and straight inflorescence, equally disjoin them. They consist for the most part of gay-flowered herbaceous plants, natives chiefly of North America. The genera *Collomia*, *Phlox*, *Leptosiphon*, *Gilia*, and *Polemonium* are common objects of cultivation, on account of their beauty; as also is *Cobæa*, a climbing plant which grows with great rapidity, and is much used during the summer for covering trellis-work and places which require to be decorated with foliage for a few months. None of the order are of either economical or medicinal value



Polemonium cæruleum.

1, a calyx, style, and stigma; 2, a transverse section of the ovary; 3, a capsule; 4, a perpendicular section of a seed, showing the embryo; 5, a corolla laid open.

POLI, JOSEPH XAVIER, was born at Molfetta in the kingdom of Naples, in 1746. He was educated at the university of Padua, under the celebrated Facciolati: he was also the pupil and friend of Morgagni, and fellow-student with Scarpa, with whom he studied anatomy and medicine. On the termination of his education he entered the army, and his scientific and literary acquirements becoming known to Ferdinand I., he appointed him, in 1776, professor of military geography at Naples. The king also sent him into France, Germany, England, and Holland, to visit the different foreign military academies. During his travels he became acquainted with many eminent scientific men in the countries which he passed through. In England he met with Herschel, Banks, and John Hunter, and he acquired much information from Hunter on comparative anatomy and on the mode of preparing specimens in natural history. While in London he was elected a member of the Royal Society. On his return home he was appointed professor of experimental philosophy at Naples, and he afterwards undertook the office of tutor to the hereditary prince, and became director of the military academy at Naples. He always highly enjoyed the confidence and favour of the royal family, and he accompanied them to Sicily during the French revolutionary war. He died at Naples in 1825.

Though he successfully cultivated other branches of science and literature, Poli owes his celebrity to his researches in comparative anatomy and natural history: his attention was particularly directed to the study of the testaceous mollusca. While travelling in Italy and abroad, he formed a very fine collection of shells, which was purchased of him by the Neapolitan government. He determined however to be something more than a simple conchologist, and diligently investigated the structure and habits of the animals that inhabit the shells, which had hitherto almost escaped attention. The results of his labours were published in a splendid work denominated 'Testacea utriusque Siciliæ eorumque Historia et Anatome,' folio, Parma. Two volumes appeared in 1792-5, illustrated with thirty-nine beautiful plates engraved on steel. These contain the multivalved and bivalved testacea, and cost the author twelve years of research. The third volume, embracing the univalves, was delayed by the political troubles with which the country was agitated; and though nearly completed, was not published until 1826, after the death of the author: it contains eighteen plates, making fifty-seven in all. This sumptuous work is as remarkable for the value of the text as the beauty of the plates. The structure, habits, locality, and mode of capture of the different molluscs inhabiting the southern coasts of Italy are accurately described; as well as the form, colour, and other peculiarities of the shells in which they are contained. Poli discovered many new and interesting anatomical and physiological facts, as well as new genera and species; and his descriptions are mostly very accurate. He fell however into some errors, the principal of which was that of mistaking the nerves of these animals for lymphatics. This mistake arose from the circumstance of the former organs in the mollusca being surrounded by a loose cellular sheath, which may be easily injected with quicksilver. The first discovery of the nervous system of the testacea is due however to Poli, though he mistook its nature.

He also wrote several works on geography, and some Italian poems.

POLICASTRO. [SALERNO, Province.]

POLICE is that department of government which has for its object to secure the safety, peace, and convenience of the community. Its primary object then is the prevention of crime and the pursuit of offenders; but besides this the police system is subservient to other purposes, such as the suppression of mendicancy, the preservation of order in great thoroughfares, the removal of obstructions and nuisances, and the enforcing of those local and general laws which relate to the public health and comfort.

In the Anglo-Saxon times the whole community was called upon to aid in protecting life and property; and the spirit of this system, though the system is no longer applicable to the existing state of society, still characterises this department of our institutions. The object of the present notice will be to give some account of the former and present constitution of the police in England.

In the Anglo-Saxon period the sheriff of each county, chosen by the freeholders in the folkmote, was the chief officer who was responsible for the conservation of the peace; and in his half-yearly visitations to each hundred in the county, he inquired whether there was any relaxation in the efficiency of the means for effecting this object. The hundred originally consisted of ten divisions, each containing ten freeholders, mutually pledged to repress delinquencies within their district. All males above the age of twelve were obliged to appear at the sheriff's visitation, to state the district to which they belonged, and to be sworn to keep the peace. One out of every ten freeholders had precedency of his companions, and the whole were bound to bring delinquents to justice within thirty days on pain of being themselves liable to penalties. The population was thinly scattered; every man was known to his neighbours; and no man could depart from his dwelling without the consent of his fellow-pledges; and the consent of the sheriff was necessary to enable a man legally to go out of his own county. No man could enter a neighbourhood without being recognised as a stranger, and probably exciting suspicion; and this suspicion, quickened by the responsibility of the freeholders, soon caused a hue and cry if the stranger could give no good account of himself. [HUE AND CRY.]

After the Conquest, the advantages of the system were recognised by several of the Norman kings, particularly by William I., and by Henry I. in the early part of his reign. The former ordered that every freeman should be under pledges, and the latter that views of frank-pledge should be taken in order that none might escape responsibility. But a great innovation was made in the Anglo-Saxon system, when the sheriff, instead of being elected by the freeholders, was appointed directly by the king. He would doubtless be generally a Norman, and therefore indisposed to meet the people in their popular courts: at all events the sheriff's 'tourn,' or half-yearly visitation, came in no long time to be neglected.

When Henry I. instituted the office of justices-itinerant [CONSERVATORS OF THE PEACE], the functions of the sheriff became of still less importance. By the stat. Merton, c. 10, passed 20th Henry III. (1236), freemen who owed suit to the county or hundred court were allowed to appear by attorney. The stat. Marl., c. 10, c. 24, passed in the 52 Henry III. (1268), dispensed with the attendance of the baronage and clergy at the sheriff's court unless their attendance was specially required; and it also prohibited the justices-itinerant from amercing townships on account of persons above the age of twelve years not having been sworn in pledges for keeping the peace. By these various measures the antient system was greatly impaired; and the new laws which were introduced from time to time for the purpose of repressing crime do not seem to have been very successful. In 1277, nine years after the passing of the statute of Marlborough, the absence of 'quick and fresh pursuit' of felons is noticed as an evil which was increasing. To supply the energy and alacrity of the old system, fines and penalties were imposed by the stat. Westminster, prim. 3 Edward I., sec. 9, on all who neglected to pursue offenders. The statute directs that 'all generally be ready and apparelled at the commandment and summons of the sheriffs, and at the cry of the county to pursue and arrest any felons when any need is.' The statute of Winchester, 13 Edward I. (1285), endeavoured to maintain the spirit of the Anglo-Saxon laws by making the county or hundred responsible in case of a delinquent not being forthcoming, and the duty of apprehending him was cast upon all the king's subjects. This statute also regulated the office of constable, an officer who had succeeded the Anglo-Saxon hundred or tything man. [CONSTABLE.] The constables were directed what measures they were to take for preventing crime and keeping the peace. In every town, village, and tything they were to set a watch according to the size of the place, every night from Ascension till Michaelmas, from sunset to sunrise; and the watchmen were to apprehend and examine all strangers, and on their refusal to obey the summons of the watchmen, they might levy hue and cry to take them. The gates of all walled towns were to be shut from sunset to sunrise: the highways were to be kept clear of bushes, woods, or dykes for the space of two hundred feet from hedge to hedge, so that felons might not conceal themselves. Every man was to have arms in his house for preserving the peace; and the constables were empowered to take the view of such arms. The prevention of crime, as well as the pursuit of criminals, was also one of the primary duties of constables, and they were charged to make presentment at the assizes, sessions of the peace or leet, of all blood-sheddings, affrays, outcries, rescues, and other offences against the peace. The justices to whom these presentments were made in the first instance, reported directly to the justices-itinerant, or at once to the king or his privy-council; and the supreme executive made provisions accordingly. At the same time the responsibility cast upon the hundred quickened the vigilance of the inhabitants; and this responsibility extended to individuals in many cases. The following extracts from the Year-Books of the Exchequer are instances of this: '16 Edward I., Sussex: murder and robbery—township of Tyndon amerced, because it happened by day, and they did not take the offender.' '6 Edward II., Kent: manslaughter (upon a sudden quarrel) committed in the highway of Wrotham—three bystanders amerced because they were present when the aforesaid Robert killed the aforesaid John, and did not take him.' And in the reign of Elizabeth the popular vigilance which this system had created leads a writer of that day to remark that 'every Englishman is a serjeant to take the thief, and who showeth negligence therein do not only incur evil opinion therefore, but hardly shall escape punishment.' Thus the Anglo-Saxon system of mutual protection having fallen to decay, the spirit of vigilance which characterised it was in some measure replaced by the greater energy and activity of the supreme executive. In process of time great social and political, and, it may be added, physical changes have rendered both systems equally incapable of effecting the objects for which they were intended.

Instead of being almost entirely engaged in agriculture, the population is now occupied in an extraordinary diversity of employments and pursuits, many of them occasioning and requiring a high degree of intellectual cultivation. Persons so engaged, and the more numerous class who live by manual labour, cannot now follow up the 'quick and fresh pursuit' of felons, at the cry of the hundred or county, from the incompatibility of such a duty with their ordinary pursuits and their daily labour. By a rural population, consisting in a greater proportion of persons having property at stake, and armed for the purpose, the call of the sheriff would be attended to with alacrity, and the excitement of the pursuit would probably be far from disagreeable. But now such a pursuit would be quite ineffectual: an offender may have committed a robbery in Lancashire in the evening, and be concealed in the metropolis by the next morning. As a consequence of these various changes, it has not been possible to render the hundred responsible for the delinquences committed within its limits, and the inhabitants being now, except in a few cases (7 & 8 Geo IV., c. 31), free from such responsibility, they are naturally careless respecting either the prevention of crime or the apprehension of criminals. And while the disposition of the community to aid the public force in these duties was gradually diminishing, the duties of the constable became much more complicated, and required the whole of the time of those who fulfilled them. The same necessity which had rendered a standing army, instead of a militia, a more useful division of employment, had become equally urgent in the case of those on whom devolved the duty of keeping the peace and watching over the security of the community. Instead however of the constabulary force being re-organised, and adapted to a new state of society, it was suffered to remain, with weaker powers, to cope with circumstances which demanded increased vigilance, activity, and intelligence. The office of constable, which, to be competently fulfilled, required a complete devotion to the purposes for which it was instituted, remained still a yearly appointment, and one so obnoxious, that persons were thrust into it who were incapable of executing the duties. Under the most favourable circumstances, the loss of time and the scanty remuneration offered no inducement to exertion; and if the duties were performed with something like energy, by the farmer or small tradesman during his year of office, they were performed at the risk perhaps of injuring their private interests. A power so constituted cannot effectually prevent crime; and it is equally inefficient for the purposes of inquiry and presentment. The parish constable usually acts only when called upon by some private party, and the services of the constabulary force are only combined occasionally, when any evil has become so extensive as to excite loud complaint, and then the absence of general regulations and rules of discipline renders their services of comparatively little value. In the manufacturing districts, when any disturbance is apprehended, such a force is useless, and the practice is either to swear in a large number of special constables, or to call in the aid of the military power. The former proceeding is found to be very inefficacious, as the special constables are deficient in the necessary degree of discipline, and they are as timid in the performance of their duties as they are unwilling to undertake them. The appearance of controlling a district by military force is an evil which, under present circumstances, cannot be avoided in many cases. The want of confidence in the old police force is also attested by the existence of upwards of five hundred voluntary associations for the apprehension and prosecution of felons: their funds are expended in the prosecution of criminals, rather than in the prevention of crime. Some of these associations have rules which bind the members, as in the case of horse-stealing, to take horse, and join in the pursuit of the thief. Railway Acts bind the companies to maintain a police during the formation of the line. An act was passed in August, 1840 (3 and 4 Vict., c. 50), entitled 'An Act to provide for keeping the peace on canals and navigable rivers.' Private watchmen are also extensively employed in docks and warehouses.

To correct the various evils incident to the constitution of the present rural constabulary, the magistrates of Cheshire, in 1829, made the first provincial attempt to improve the administration of police in their county, and they obtained an Act (10 Geo. IV., c. 97) which authorised them to appoint and direct a paid constabulary. A more successful attempt was made at Barnet by a voluntary association, which at first engaged two officers only to patrol a limited district. The plan was found so advantageous, that it was adopted in a more extensive circle. These isolated examples however render the adjacent unprotected districts in a worse state than they were before. The establishment of a new police force for the metropolis, in 1829, has done more towards exhibiting the advantages of employing a trained body of men for all the purposes for which the old constabulary was appointed, than any other circumstance. Viewed at first with suspicion and dislike, from its somewhat military organization, the clamour with which it was assailed has died away, and public opinion is now steadily in its favour. Each parish had formerly managed its own police affairs; and before 1829, the total police force of the metropolis consisted of 797 parochial day officers, 2785 night watch, and upwards of 100 private watchmen: including the Bow-street day and night patrol, there were about 4000 men employed in the district stretching from Brentford-bridge on the west to the river Lea on the east, and from Highgate on the north to Streatham on the south, the city of London being excluded. The management of this large force was of varied and often of conflicting character. The act of parliament creating the new police force (10 Geo. IV., c. 44) placed the control of the whole body in the hands of two commissioners, who devote their whole time to their duties: they are immediately responsible to the home secretary of state. By the 2 & 3 Victoria, c. 47, the metropolitan police district may be extended to any parish or part of a parish situated within 15 miles of Charing Cross, the first act having limited its operation to a distance of twelve miles. The number of men of each rank serving in the metropolitan police force, in January, 1840, was as follows:—

		Salary.	
1	Inspecting Superintendent .	£400	0
1	Superintendent . .	300	0
16	ditto . . .	250	0
73	Inspectors . .	118	6
349	Sergeants . .	63	14
250	Constables, 1st class . .	54	12
2,527	ditto 2nd „ . .	49	8
269	ditto 3rd „ . .	44	4

The sergeants and constables are allowed clothing, and each married man of these two ranks is allowed 40 pounds weight of coals weekly throughout the year; each single man is allowed 40 pounds weight weekly during six winter months, and 20 pounds weight weekly for the remainder of the year.

The total number of the force is 3486, who are placed in divisions, each division being employed in a distinct district. Every part of the metropolis is divided into 'beats,' and is watched day and night. The total disbursement on account of the force, for the year 1839, amounted to 221,993*l.*, one-fourth of which is paid by the treasury out of the public revenue, and the other three-fourths by the respective parishes. Since August, 1839, the horse patrol, consisting of 71 mounted men, who are employed within a distance of several miles around London, has been incorporated with the metropolitan police. The Thames police consists of 21 surveyors, each of whom has charge of three men and a boat when on duty. The establishment is under the immediate direction of the magistrates of the Thames Police-office. The city of London still manages its own police affairs, which have been placed under a far more efficient system since the establishment of the metropolitan police force. In 1833 the number of persons employed in the several wards of the city was—ordinary watchmen, 500; superintending watchmen, 65; patrolling watchmen, 91; beadles, 54—total, 710. The number of men on duty in the city at midnight is about 400. The expense of the day police, consisting of about 120 men, amounts to about 9000*l.* a-year, and is defrayed by the corporation; and the sums levied on the wards for the support of the night-watch average about 42,000*l.* per annum. In addition to the paid watchmen, about 400 ward constables are appointed.

The police of the metropolis and the district within fifteen miles of Charing Cross (exclusive of the city of London) is regulated by the Acts 10 Geo. IV., c. 44, and 2 and 3 Vict., c. 47, and together they form the police code for nearly a seventh part of the population of England and Wales.

The officers and men of the metropolitan police have been at various times engaged in 200 places to protect the peace when the local force has been found incompetent. In nearly all the boroughs constituted under the Municipal Reform Act (5 & 6 Will. IV., c. 76) a paid police force has been established as nearly as possible on the same footing as the metropolitan police. In the metropolis, 'when any burglary or serious offence is brought to the knowledge of the police, the superintendent or other officer of the division or subdivision where the offence has occurred immediately examines the circumstances, or makes a precognition and a report upon them and the measures taken in consequence. . . . . A daily report or presentment is made to the commissioners of all the chief occurrences which have taken place during the preceding twenty-four hours in every division of nearly two counties, upon which presentment such instructions are given as any special circumstances may seem to require. Upon other reports, made at such intervals as to comprehend general results, if it shall appear that in any district there has been an influx of depredators, additional strength is directed upon it, or explanations are required if any marked evil appear to continue without abatement.' The state of things under the former 'disjointed and conflicting system is thus described in the Report of a Select Committee of the House of Commons in 1834:—'The police was roused into earnest action only as some flagrant violation of the public peace or some deep injury to private individuals impelled it into exertion; and security to persons and property was sought to be obtained, not by the activity and wholesome vigour of a preventive police, which it is the paramount duty of a state to provide, but by resorting from time to time, as an occasional increase of the more violent breaches of the law demanded it, to the highest and ultimate penalties, in the hope of checking the more desperate offenders.' Not only is the metropolitan police active night and day in preventing depredations and suppressing mendicancy, but its attention is directed to giving assistance in case of accidents, reporting nuisances and obstructions, and in keeping a vigilant eye upon the recesses of profligacy and crime. The same services are performed with more or less efficiency in the large towns which have the services of a trained body of men.

The difficulty of re-organising the rural constabulary has hitherto retarded the general improvement of this force, while the increased vigilance of the towns has rendered such a measure more imperative. In October, 1837, a commission was appointed under the crown 'to inquire into the best means of establishing an efficient constabulary force in the counties of England and Wales;' and the commissioners having taken means to ascertain the opinions of the magistracy in each petty-sessional division in the country, it was found that, out of 435 divisions, the magistrates in 123 of them recommended the appointment of a paid rural police; in 13 divisions they recommended such a force, with a proviso that it be placed under their exclusive control; in 77 divisions the appointment of a patrol or of additional constables was recommended; in 16, the better remuneration of the present constables; in 37 divisions it was considered that further security was necessary; and in 122 divisions an opinion was given that no alteration was required. The local magistracy are in many instances jealous of the interference of the supreme executive; yet, notwithstanding, the balance of opinion is in favour of an alteration. The evils of the present inefficient system are fully described in the Report of the Constabulary Commissioners (No. 169, Session 1839). Some of their recommendations involve questions of provincial organization, which render it very difficult to bring a uniform system of police administration into general operation. In a bill introduced into the House of Commons in 1839, an attempt was made to remove some of these obstacles, and a very clear and detailed account of the plan was printed with the bill (No. 71, Session 1839); but the measure was regarded as too elaborate, and introduced so many innovations as to occasion its ultimate rejection.

The following is a brief summary of the principal reasons which induced the Constabulary Commissioners to recommend the appointment of a paid police force in lieu of the present parish constables:—The want of organization in any existing force has encouraged crime, and each person living by depredations costs much more to the community than a paid constable. Besides the expenses of judicial establishments, a sum exceeding 2,000,000*l.* is paid annually in England for the repression of crime, while the means for the attainment of this object are imperfect and inefficient. Even the money at present contributed by voluntary associations for self-protection would, it is thought, go far towards obtaining an effective combined force; and there would be also the saving of time to several thousand persons now annually forced into almost useless service as constables, or a saving of money which is paid for substitutes. The extent of the force required is estimated at rather more than 8000 men, and the annual cost at a sum below 450,000*l.*, including expenses of management and other charges, the whole not exceeding 1¼*d.* in the pound on the valuation of real property in England and Wales in 1815; and it is proposed that one-fourth of the annual cost be defrayed out of the consolidated fund, and the other three-fourths out of the county rate. The average number of commitments in England is upwards of 100,000 annually, which number, it is assumed, represents a total of 40,000 persons living wholly by depredation, to which must be added those who live partially by such means and escape detection, to meet which active body a trained force of 8000 men appears to be a moderate estimate. The commissioners recommended that a disposable force of 300 or 400 additional men be kept for extraordinary services. The patronage connected with a paid constabulary should be vested in those who are directly responsible for its efficiency; and local supervision and control might be made consistent with this arrangement. The success of such a force would of course depend to a great extent upon its being seconded by popular feeling, and, contrary to the opinion of many persons, it would be less likely to infringe upon personal liberty than a body of isolated individuals, as an acquaintance with legal duties forms part of the training of a combined force, which must in all cases have general rules for its conduct and government. Should a trained constabulary be established, the commissioners recommended that the men be changed from one district to another in the same manner as the officers of the Excise establishment.

The government has not thought proper to take any steps for the general establishment of a trained constabulary force in England and Wales; but in 1839 an act was passed (2 and 3 Victoria, c. 93) enabling the magistrates to appoint county and district constables, thus leaving the improvement of the police to their discretion. The act empowers the magistrates assembled in quarter-sessions to report to the secretary of state the necessity of appointing additional constables, but not in a greater proportion than one constable to each one thousand of the population; the expenses to be charged upon the county-rate in the several divisions in which the force has been appointed. To secure unity of action and general uniformity, the secretary of state is to frame rules for the regulation of the new force. The men employed in it are not to exercise any other employment, and are not allowed to vote at elections for a member of parliament. The provisions of this act have been adopted by the following counties or districts of counties:—Bedfordshire, Bucks, Cumberland, Durham, Essex, Gloucester, Hants, Lancashire, Leicestershire, Norfolk, Northamptonshire, Notts, Salop, Stafford, Suffolk, Warwick, Wilts, Worcester, and Glamorganshire. A Parliamentary Return (No. 363, Sess. 1840) shows the estimated expenses of the new constabulary force in each of the above counties, and the additional rate in the pound which it will be necessary to levy for its maintenance.

In August, 1840, an act received the royal assent (3 and 4 Victoria, c. 88) amending the act of the previous session for facilitating the establishment of a paid constabulary. It removed the restriction in the previous act which limited the appointment of constables to a proportion not exceeding one to each one thousand of the inhabitants; and made provisions for the consolidation of the borough and county police in cases where the respective authorities desire to enter into such an arrangement.

In addition to the two acts above mentioned, the following statutes enable magistrates to obtain any additional police force which may be requisite to ensure the conservation of the peace:—1, The 3 and 4 Wm. IV., c. 90, entitled 'An Act to repeal an Act of the 11th year of his late Majesty King George IV., for the lighting and watching of parishes in England and Wales, and to make other provisions in lieu thereof, by which the rate-payers can tax themselves for the purpose of watching.' This act is intended to supersede the necessity of each parish incurring the expense of obtaining a separate local act. 2, The Act 1 and 2 William IV., c. 41 (amended by the 5 and 6 Wm. IV., c. 43), relates to the appointment of special constables, and the title sufficiently explains its object:—'An Act for amending the laws relative to the appointment of special constables, and for the better preservation of the peace.' Under this statute special constables may be sworn in on apprehension of a breach of the peace, and they may be paid out of the county rate. The act also enables the magistrates to obtain the services of the metropolitan police, and provides in like manner for their payment.

POLICY and POLITY. Policy is generally used to signify the line of conduct which the rulers of a nation adopt on particular questions, especially with regard to foreign countries, and according to our opinion of that particular line of conduct we say that it is good or bad policy. Polity has a more extended sense, being synonymous with the principles of government, and this is the sense of the Greek 'politeia' (*πολιτεία*), from which it is derived. Police, in an extended sense, is that branch of polity which is concerned with the internal economy of the state. In a more restricted sense it is a branch of preventive administration, distinct from the administration of justice, the object of which, among other things, is the punishment of crimes committed.

POLICY. [Insurance.]

POLIDO'RO DA CARAVA'GGIO. [Caravaggio.]

POLIGNAC, MELCHIOR, CARDINAL DE, born at Puy in Languedoc, in 1661, of an illustrious family studied at Paris, and took holy orders. He accompanied Cardinal de Bouillon to Rome in 1689, and was employed as a negotiator to settle some differences between France and the court of Rome. In 1693, the Abbé de Polignac was sent by Louis XIV. as ambassador to Poland, where, after the death of John Sobieski, in 1696, he contrived to have François Louis de Bourbon, prince of Conti, proclaimed king of Poland by the majority of the electors. But another party proclaimed Frederic Augustus, elector of Saxony, who was at length acknowledged by the whole nation. [AUGUSTUS II.] Louis XIV., being displeased, recalled the Abbé de Polignac, and banished him to his abbacy at Bonport, where he employed himself in writing his poem in refutation of Lucretius. Being recalled to court after some years, he was appointed by Louis XIV., in 1706, auditor of the rota at Rome, a court which is concerned about questions of ecclesiastical benefices and other clerical temporalities throughout the Catholic world. In 1709 he returned to France, and in 1710 he was sent to Holland to negotiate the general peace. He was one of the French plenipotentiaries at the congress of Utrecht. In 1713 he was named cardinal. In 1724 he went to Rome as minister of France. In 1732 he returned, and he died in 1741, at a very advanced age. Cardinal Polignac was a member of the French Academy, of the Academy of Sciences, and of that of Inscriptions and Belles Lettres. (*Eloge du Cardinal de Polignac*, Paris, 1742.)

His Latin poem, 'Anti-Lucretius, sive de Deo et Natura libri novem,' Paris, 1754, is a refutation of the system of Lucretius, and intended as a demonstration, from evidence afforded by the works of the creation, of the existence of a Supreme Being, the maker and regulator of all things. Some of the descriptions are very fine; the style resembles that of Virgil. The ninth book was left unfinished by the author, and the whole poem was not published till after his death. The 'Anti-Lucretius' has been translated into French and Italian.

POLIGNY. [JURA, Department.]

POLINICES, De Montfort's genuine name for *Natica Mammilla* (*Nerita Mammilla*, Linn.), his *Polinices albus*, and other similar forms.

POLITICAL ECONOMY is the name given to a department of knowledge the limits of which are not yet accurately defined. The word economy, applied to domestic concerns, means the art of well administering the private affairs of a family, of regulating its expenditure according to its income, and providing for the wants of the members of the household. By analogy, political or 'public' economy has been considered by many as conversant about the principles of administering the wealth of a country with a view to its increase, regulating the expenditure, providing for the wants of the people, and endeavouring to maintain and increase their comforts. But by taking such an extensive view of the subject, most writers, and especially continental writers, have considered it necessary to investigate all the causes of the prosperity of nations, and have involved themselves in multifarious discussions on the various forms of government and of civil institutions which are supposed to affect the economical condition of a people. By so doing they have encroached upon the science of general politics and legislation, and have brought forward their own theories of laws, ethics, and administration, with the view of showing their influence on the social state. But it is evident that such a vast field of inquiry must exceed the powers of any single writer, and that the attempt to embrace so many difficult and varied subjects under one division of knowledge, tends to confuse rather than to elucidate. Modern writers, especially in England, have therefore limited their inquiries to the principles which govern the production and accumulation of wealth, and its distribution and consumption. 'The Wealth of Nations' was the title which Adam Smith gave to his work. In this consists the main difference between the modern English and the Italian and French economists. The latter maintain that the political economist is concerned not only with the aggregate production of wealth, but with its most beneficial distribution among individuals, not only with wealth in short, but with happiness also. The modern English writers, on the contrary, say that the appropriate subject of the political economist is not happiness, but wealth; that wealth is confined to material objects, the produce of land and of industry; that the political economist who assumes to explain the phenomena of the production of wealth ought to lay down the general principles on which wealth is produced, as they are deducible from actual facts; it is the business of the statesman, the philosopher, or the politician, to say what he thinks best for the general prosperity of society, after he has examined the evidence of the political economist, which is an essential part of the evidence, but not the sole evidence to be attended to in the conduct of a nation's affairs. But here the English economists also seem to be divided among themselves. Some appear to think that the principles of political economy, as the term is understood by them, may be deduced with the certainty of mathematical demonstration, whilst others assert that there are many important propositions in political economy which require limitations and exceptions. 'The desire to simplify and generalise has occasioned an unwillingness to acknowledge the operation of more causes than one in the production of particular effects; and if one cause would account for a considerable portion of a certain class of phenomena, the whole has been ascribed to it without sufficient attention to the facts which would not admit of being so solved.' (Malthus, *Principles of Political Economy*, 'Introduction.') Malthus quotes the controversy on the bullion question as an instance of this kind of error. He afterwards goes on to say, 'Adam Smith has stated that capitals are increased by parsimony, that every frugal man is a public benefactor (*Wealth of Nations*, b. ii., ch. 3), and that the increase of wealth depends upon the balance of produce above consumption (b. iv., ch. 3). That these propositions are true to a great extent is perfectly unquestionable. No considerable and continued increase of wealth could possibly take place without that degree of frugality which occasions annually the conversion of some revenue into capital, and creates a balance of produce above consumption; but it is quite obvious that they are not true to an indefinite extent, and that the principle of saving, pushed to excess, would destroy the motive to production. If every person was satisfied with the simplest food, the poorest clothing, and the meanest houses, it is certain that no other sort of food, clothing, and lodging would be in existence; and as there would be no adequate motive to the proprietors of land to cultivate well, not only the wealth derived from conveniences and luxuries would be quite at an end, but, if the same division of land continued, the production of food would be prematurely checked, and population would come to a stand long before the soil had been well cultivated. If consumption exceed production, the capital of the country must be diminished, and its wealth must be gradually destroyed, from its want of power to produce; if production be in a great excess above consumption, the motive to accumulate and produce must cease from a want of will to consume. The two extremes are obvious; and it follows that there must be some intermediate point, though the resources of political economy may not be able to ascertain it, whereby, taking into consideration both the power to produce and the will to consume, the encouragement to the increase of wealth is the greatest. The division of landed property presents another obvious instance of the same kind. No person has ever for a moment doubted that the division of such immense tracts of land as were formerly in possession of the great feudal proprietors must be favourable to industry and production. It is equally difficult to doubt that a division of landed property may be carried to such an extent as to destroy all the benefits to be derived from the accumulation of capital and the division of labour, and to occasion the most extended poverty. There is here then a point, as well as in the other instance, though we may not know how to place it, where the division of property is best suited to the actual circumstances of the society, and calculated to give the best stimulus to production and to the increase of wealth and population.' (Malthus, *Introduction.*)

We cannot enter into anything like an examination, however brief, of the principles of political economy; but we shall merely state a few general propositions which are universally acknowledged as true. 1. Every man desires to obtain additional wealth with as little trouble to himself as possible. 2. The increase of population is limited either by physical or moral evil, or by prudential motives. 3. The powers of labour, and of the other instruments which produce wealth, may be indefinitely increased, by using their products as the means of further production. 4. Agricultural produce is not susceptible of the same unlimited increase as manufactures. The principal topics discussed by political economists are: 1, the definition of wealth; 2, of productive and unproductive labour; 3, on the nature and measures of value; 4, on the rent of land; 5, the wages of labour; 6, the profits of capital; 7, the results of machinery; 8, the circulating medium, or currency; 9, the nature and conditions of commerce, or exchange of commodities. Most of these subjects are treated in this work under the heads ACCUMULATION, BALANCE OF TRADE, BULLION, CONSUMPTION, CURRENCY, EXCHANGE, PROFIT, RENT, WAGES, WEALTH.

History of the Science.—The great nations of antiquity, the Greeks and Romans, had no notion of what we understand by political economy. They sought to increase their wealth chiefly by war, by conquering and plundering weaker nations, and appropriating to their own use part of the produce of their industry. They considered handicraft and trade as degrading to a citizen, and left those pursuits to be exercised by slaves or freedmen. The Romans, in the earlier ages of the republic, held agriculture in more esteem; but after they had extended their conquests beyond the limits of Latium, the business of agriculture also was mainly conducted by slaves. The consequences of this system are well known; agriculture declined, and the people of Rome were obliged to be fed by corn from the provinces. It is evident that in such a state of society there will be no room for the consideration of some of the most important questions of political economy, which are based upon the principles of free labour and competition. It appears that the Romans considered gold not as the representative of wealth, but as wealth itself, for we find that the senate forbade its exportation. (Cicero, *Pro Flacco*, 28.)

After the fall of the Roman empire, the free towns that rose in the middle ages, Pisa, Venice, Florence, Genoa, and the Hanseatic towns, were essentially commercial, and with them the 'mercantile' system, as it is called, may be said to have originated, at least in practice; for it was not expounded and reduced to rules until centuries after. This system consisted in looking to foreign trade as the source of wealth, selling dear and buying cheap, and thereby realising, by the exchange, a surplus in bullion, which surplus was employed in increasing the quantity of produce to be sold. Shipping, foreign marts, colonies or factories abroad, were the means employed for these objects. But as each mercantile nation sought a monopoly of trade, restrictions were resorted to in order to favour its own commerce and impede or depress that of others. This led to jealousies and wars, which ended with the ruin of one or the other of the contending parties. This system was narrow and exclusive: it considered only one state, and built the prosperity of that state on the depression of others. It was affected by the same error as the military system of conquerors, who wish to exalt and enrich one country by subjugating and plundering another, overlooking the fact that the prosperity of other countries is part of the general prosperity of the world, in which our own country must share. The principle that 'the whole world as to trade is but as one nation or people, and therein nations are as persons' (Sir Dudley North's *Discourses on Trade*, 1661), was not known as yet, and indeed it may be said to be hardly known, or at least acknowledged, even now, except by very few, in any country.

Another mistake of the states of the middle ages was that of considering gold and silver as constituting the exclusive wealth of a country; their attention was fixed on money not as a means, but as the end of trade, and as the most beneficial surplus, which they endeavoured to retain in their coffers by enacting severe penalties against its exportation. Hence the earlier Italian writers on commerce treat exclusively of money, its standard, and the evils of tampering with it. Gasparo Scaruffi, of Reggio near Modena, wrote, in 1579, 'Discorso sopra le Monete, e della vera proporzione frà l'oro e l'argento.' In 1588 Bernardo Davanzati of Florence wrote a short treatise, 'Sulle Monete,' and another 'Sui Cambj,' or 'The Exchanges.' Antonio Serra, a native of Cosenza in Calabria, published, in 1613, 'Breve Trattato delle Cause che possono far abbondare i Regni d'Oro e d'Argento.' Looking upon gold and silver as constituting the wealth of a state, Serra investigates the means of making them flow abundantly into a country. Among these means he reckons manufactures, 'which afford a much greater return than agriculture;' and maritime commerce. But 'these means,' adds Serra, 'are of no avail without fixed laws, order, and security for persons and property, for there can be no prosperity where there are continual changes of dynasties and laws.' This shows that Serra, considering the age and country in which he lived, had formed some correct and extended notions of political economy. His book however remained unnoticed, and the author, being implicated, as it seems, in some conspiracy against the Spanish rulers of Naples, was imprisoned for ten years, and underwent the torture seven times. It is not known when and where he died. Turbolo of Naples wrote several treatises on the coinage and the state of money in the kingdom of Naples: 'Discorsi e Relazione sulle Monete del Regno di Napoli,' 1616, 1618, 1623, and 1629. Geminiano Montanari of Modena published, in 1680, 'Trattato Mercantile delle Monete,' and afterwards, 'Trattato del Valore delle Monete in tutti gli Stati,' in which he lays down sound principles for regulating the coinage.

The first writers on the subject of commerce at large appeared in England. Raleigh wrote, in 1595, his 'Essay on Trade;' Edward Misselden wrote his 'Circle of Trade,' in 1623, and Louis Roberts his 'Treasure of Traffic,' in 1641. Thomas Mun wrote, in 1621, his 'Defence of the East India Trade,' in which he exploded the notion that money exclusively constituted wealth. He compared the exportation of gold and silver wherewith to buy goods for importation, with the seed which the husbandman throws into the earth that he may reap a plentiful harvest; and in his 'Treasure of Foreign Trade,' published in 1664, Mun advocates the same principle. But Sir William Petty went further than any of his predecessors or contemporaries in asserting enlarged views of political economy. In his treatise 'On Taxes and Contributions,' published in 1667, he was the first to state, though in an incidental manner, that 'it was the labour required for the production of commodities which determined their value.' He also wrote his 'Quantulumcunque,' a treatise on money, in which he condemned the laws regulating the rate of interest, and combated the notion that a country may be drained of cash by an unfavourable balance of trade. [PETTY, SIR WILLIAM.]

In France, the minister Colbert, a contemporary of Sir William Petty, was a great promoter of the mercantile system in all its exclusiveness [COLBERT], and the principles of that system continued to prevail in France after his death till the time of Quesnay. Pierre le Pesant, Seigneur de Bois Guibert, published, in 1695, his 'Détail sur la France,' in which he treated both of commerce and money, but the author was banished because some of his propositions reflected upon feudal rights and ecclesiastical privileges. Twelve years later Vauban published his 'Dixme Royale,' in which he proposed a new plan of taxation.

In England, Locke, in his 'Essay on Civil Government' (b. xi., 40-43), argued at length to prove that 'labour is the constituent principle of value.' There is something to the same purpose in Hobbes's 'Leviathan' (ch. 24). But these were incidental remarks, and not professed investigations on the subject of political economy.

In a tract published in 1677, entitled 'England's Great Happiness,' the notion of the balance of trade is examined and its fallacy exposed. [BALANCE OF TRADE.] Sir Dudley North, already quoted, wrote 'Discourses on Trade,' 1691, which contain more clear and comprehensive notions on trade than had yet been published. Among other propositions, he lays it down as a maxim that 'there can be no trade unprofitable to the public; for if any prove so, men soon leave it off, and wherever the traders thrive, the public, of which they are a part, thrive also.' It is worthy of notice, by way of contrast, that Montesquieu in the following century wrote a chapter entitled 'To what Nations Commerce is prejudicial.' (*Esprit des Lois*, b. xx., ch. 21.) In 1696 Davenant wrote on 'the Commerce and Revenue of England.' In the next century Sir Matthew Decker wrote an 'Essay on the Causes of the Decline of Foreign Trade,' 1744.

A change of opinion was in the meantime taking place on the Continent with respect to the so-called 'mercantile system.' François Quesnay, born in 1694, a medical man by profession, and surgeon to Louis XV., being struck by the distressed condition of the French peasantry, endeavoured to draw the attention of the government towards relieving that numerous and ill-used class of people. He proposed the abolition of custom-houses between province and province, the free circulation of corn throughout the kingdom, the suppression of the corvées, and other similar reforms, which were effected after his death by Turgot. Quesnay went further: he assumed as a principle that the earth, or in other words, agriculture, was the only source of wealth, in opposition to Colbert's mercantile system, which fixed that source exclusively in trade. Quesnay allowed that manufactures and merchants were highly useful, but he contended that as they realised no net surplus in the shape of rent, they did not add any greater value to the raw material of the commodities which they manufactured or carried from place to place, than was just equivalent to the value of the capital or stock consumed by them during the time that they were engaged in those operations. He divided society into three classes: 1, a productive class, consisting of farmers and agricultural labourers, who subsist on a portion of the produce of the land, reserved to them as wages of labour and as a reasonable profit on their capital; 2, a proprietary class, namely, those who live on the rent of the land, or the net surplus produce raised by the cultivators, after the necessary expenses have been deducted; 3, an unproductive class, consisting of manufacturers, merchants, servants, and handicraftsmen, 'whose labour, though useful, adds nothing to the national wealth, and who subsist entirely on the wages paid to them by the other two classes.' (Quesnay, *Physiocratie, ou Constitution Naturelle des Gouvernemens*, 1768.) As a corollary to these positions, Quesnay and his disciples concluded that all taxes ought to fall upon the land.

Quesnay is considered as the head of the school called the school of the 'Economistes,' which reckoned amongst its members the Marquis de Mirabeau, father of the celebrated Mirabeau, Mercier de la Rivière, Dupont de Némours, Condorcet, Raynal, Turgot, Necker, and other distinguished men.

Quesnay's principal work on political economy is the 'Physiocratie' already mentioned; but he published other tracts, especially an article 'Sur les Grains,' which was inserted in the 'Encyclopédie,' and in which he advocates the same principles. Though Quesnay considered agriculture as the only source of wealth, he did not advocate any exclusive protection for it, but rather a principle of freedom in all branches of trade. The 'Economistes' originated the 'Cadastre,' which was a survey and valuation of all real property, made by order of the government, for the purpose of assessing the 'contribution foncière,' or property tax, which they considered as the only legitimate tax. And this principle has prevailed in France and other continental countries, where even now the tax on land and houses forms the main source of the public revenue, being from 20 to 30 per cent. on the rent.

In Italy, Antonio Bandini of Siena had asserted the fundamental principle of the 'Economistes,' long before Quesnay, in a work which however was not published till 1775. Bandini wrote his 'Discorso Economico' in 1737, with a view of drawing the attention of the Tuscan government to the desolate condition of that vast tract of country called the Maremma of Siena. Bandini advocated freedom of trade in agricultural produce, and recommended the removal of all restrictions upon importation and exportation; he urged the expediency of giving to the cultivators of the soil an interest in the land, by the grant of long leases; and lastly he recommended the removal of the numerous vexatious taxes, and the substitution of a single tax upon land, not excepting ecclesiastical and other privileged property. A MS. copy of Bandini's book was presented to the grand-duke Francis of Lorraine, who however, being soon after elected emperor of Germany, and having removed to Vienna, could not attend to the affairs of the Maremma. But his son Leopold, on coming to the government of Tuscany, consulted Bandini's work, and put into execution the plan therein proposed. The Maremma of Siena assumed a new life, and its population has nearly trebled in the course of half a century.

Antonio Broggia of Naples, a merchant by profession, wrote a treatise on taxation, 'Sul Tributi,' in which he admits that there are three sources of wealth, agriculture, handicraft or manufactures, and commerce. He does not consider the tax on land as the only legitimate tax, but proposes three sorts of taxation, land-tax, customs, and gabelle or excise. He says that in a great commercial country the customs and excise, or indirect tax, ought to be preferred, but in an agricultural country like Naples the tax on land must be the principal source of revenue. He condemns taxes on capital and persons, licences and patents, horses and agricultural implements, as detrimental to industry, as well as the government monopolies of salt, tobacco, &c. The author, who belonged to the mercantile school, falls into the error of that school, in wishing to sell as much as possible to foreigners, and buy as little as possible from them.

Ferdinando Galiani also, of Naples, ranks among the most distinguished writers on political economy in the last century. While at Paris, he wrote in French a book on the corn-trade, 'Dialogues sur le Commerce des Blés,' in which he took a middle course between those who advocated an unrestricted trade in corn, and those who wished it to be subject to permanent restrictions. Galiani contends that no universal system can be established on that important subject, and that the laws concerning the trade in corn must vary according to the situation of individual states, the nature and cultivation of their respective soils, and also their political institutions and relations to other countries. Galiani also wrote, in Italian, a work on money, 'Della Moneta,' published in 1750, which is reckoned one of the best on this subject. Taking an enlarged view, he investigated the nature of the value of things, which he said was the result of various circumstances, namely, their scarcity, utility, the quantity and quality of the labour required for their production, and also the time. He extends his investigations to the value of men's abilities, which are to be estimated not only according to their rarity, but also according to the time required for their coming to maturity, and the difficulties encountered before they can attain a station favourable to their development. This is a position analagous to that afterwards stated by Adam Smith (b. i., ch. 10), 'that the wages of labour vary with the easiness and cheapness or the difficulty and expense of learning a business.' It requires more time and expense to form a physician, or a statesman, or a divine, than a common labourer, and therefore the latter has less value than the former. Galiani combats the received opinion of his time, that high prices were a sign of distress. He also contended that the precious metals were to be considered as merchandise. Galiani may be considered as a reformer of the old mercantile system. [GALIANI.]

Gian Francesco Pagnini, born at Volterra in 1715, published in 1751 a dissertation 'Sopra il giusto Pregio delle Cose,' or the just value of things, and in 1764 a history of the Commerce of Florence, with a digression on the value of gold and silver, and its proportion to the prices of other things in the 14th and 15th centuries, compared with those in the 18th century. Both works contain sound opinions and interesting facts. Pompeo Neri of Florence wrote, in 1751, 'Osservazioni sopra il Prezzo legale delle Monete,' a work of considerable merit.

Gian Rinaldo Carli, born at Capo d'Istria in 1720, ranks with Galiani as one of the most distinguished Italian political economists. He wrote an elaborate work on coin and currency, and on the mints of Italy: 'Delle Monete e della Istituzione delli Zecche d'Italia,' 3 vols. 4to., 1754-60, in which he completely exhausted the subject. Carli also wrote 'Ragionamento sopra i Bilanci Economici delle Nazioni,' in which he combated the fallacy prevalent in his time about the balance of trade. He also discussed the subject of the corn-trade in a letter addressed to Pompeo Neri, in 1771, 'Sul Libero Commercio dei Grani,' in which he agreed with Galiani in denying the wisdom of a general principle of unrestricted freedom of trade in corn, which he thought ought to be modified according to local circumstances, because he considered the supply of corn as a subject deeply connected with administrative policy, and not a mere commercial question. Carli had a powerful mind, uninfluenced by popular opinions or prevalent systems. Other particulars concerning this distinguished writer are given under CARLI.

Antonio Genovesi, born in 1712, at Castiglione near Salerno, became professor of the new chair 'of commerce and mechanics,' founded at Naples in 1755, by Bartolommeo Intiesi, a wealthy Florentine merchant of that city. Genovesi published his lectures under the title of 'Lezioni di Economia Civile,' in 1768. Genovesi took a middle course between the mercantile system and that of the 'Economistes.' He reckoned three sources of wealth, agriculture, arts, and commerce. He extols agriculture as an ample and perennial spring of public wealth, but he also appreciates commerce and manufactures as the causes of an increase of production. With regard to commerce, he adopts the restrictive system of the mercantile school as to foreign goods, whilst he agrees with the 'Economistes' as to the freedom of trade in corn, and of internal trade in general, as well as with respect to the interest of money. He inculcates the principle that labour constitutes the capital of nations as well as of families. But he did not fall into the vulgar error of considering whole classes of society as unproductive because they are not employed in manual labour, such as men of science, scholars, lawyers, soldiers, magistrates, and others. Genovesi wrote also other treatises on political economy, which he succeeded in rendering popular in his own country.

The other Italian political economists of the eighteenth century are: 1, Francesco Algarotti of Venice, born in 1712, who wrote 'Saggio sul Commercio,' in which he extols commerce as the source of wealth and power, and he quotes the example of England. He also wrote a few short suggestions on the advantages which might be derived from Africa, in a commercial point of view, by the nations of Europe: 'Sulla Preferenza dell' Africa in confronto dell' Asia e dell' America, rapporto all' Industria e dal Commercio degli Europei.' 2, Antonio Zanon of Udine in the Venetian territory, born in 1696, a merchant by profession, wrote letters on agriculture, commerce, and manufactures, which he encouraged also by his exertions. He was a man of a liberal mind and a true philanthropist. 3, Cesare Beccaria of Milan wrote lectures on political economy, in which he expounded, among other things, the advantages of the division of labour, and he investigated the relations of wages and labour, and the nature of productive capitals. With regard to the corn-trade, he agreed with Carli and Galiani in not advising any general system. He considered large masses of property as more advantageous to a country than small subdivisions. In general, Beccaria may be considered as belonging to the school of the 'Economistes.' [BECCARIA, CESARE BONESANA.] 4, Pietro Verri, born at Milan in 1727, the intimate friend of Beccaria, although he differed from him on several points of political economy, wrote 'Memorie sull' Economia Pubblica dello Stato di Milano,' in which he shows the decline of that country during the two centuries of Spanish dominion, and ascribes it to the ignorance of its rulers and the absurdity of the laws. He wrote also 'Riflessioni sulle Leggi Vincolanti, principalmente sul Commercio dei Grani,' in which he advocated the principle of absolute liberty. Lastly, he wrote 'Meditazioni sull' Economia Politica,' which were published in 1771, and have been translated into several languages. It is an elementary but useful book. 5, Ferdinando Paoletti, born in 1717, near Florence, wrote, in 1769, 'Pensieri sopra l'Agricoltura, and, in 1772, 'Veri Mezzi di rendere felici le Societa,' in which he advocated freedom of trade. 6, Gian Battista Vasco, born at Mondovi in Piedmont, in 1733, wrote 'Saggio Politico sulla Moneta,' 1772, in which he treats of various questions of political economy. He afterwards wrote, in French, 'Mémoire sur les Causes de la Mendicité et sur les Moyens de la supprimer,' which he sent to the Academy of Valence in Dauphiné, in 1788. His other works were, 'Sulla Felicita Publica considerata nei Coltivatori di Terre proprie;' and 'L'Usura libera.' 7, Giammaria Ortes, born at Venice in 1713, wrote a work entitled 'Dell' Economia Nazionale' libri sei, 1774, which however remained unknown except to a few friends of the author, until Custodi inserted it in his great collection of the Italian economists. His views were original, and he belonged to none of the schools already established. He lays it down as a fundamental principle that the capital of a nation is always in proportion to the population, and that the only difference is in its distribution. If a portion of the population becomes richer, it can only be by impoverishing the rest. As a consequence of this principle, he asserts that all endeavours to increase industry with a view to increase the national wealth are futile. But he supports also the principle of freedom of trade between nations, because, he says, every nation has its own capital, which cannot be diminished nor increased by exchange. Ortes wrote also 'Riflessioni sulla Popolazione per rapporto all' Economia Nazionale,' 1790, in which he stated several positions which have been since developed by Malthus, such as that population increases in proportion to the increase of production; that population does not always increase with the increase of marriages, &c. 8, Filippo Briganti, a native of Naples, published, in 1780, 'Esame Economico del Sistema Civile,' in which he refutes the theories of Mably, Rousseau, and Linguet, who asserted that the state of society, and civilization, commerce, and wealth, were the origin of all the evils with which man is afflicted. 9, Gaetano Filangieri, born at Naples in 1752, is known by his work on legislation, the second volume of which treats of political economy. He belonged to the school of the French economists, but he was not a servile follower of that school. He was a supporter of the freedom of trade; he had no prejudices against luxury, but he advocated direct taxation, or the tax on land, and he maintained that large cities were injurious to the prosperity of a country. [FILANGIERI.] 10, The Marquis Caraccioli, while he was viceroy of Sicily, wrote 'Riflessioni sull' Economia e l'Estrazione dei Frumenti della Sicilia fatte ad occasione della Carestia del 1784 ed 1785.' The author, being struck with the fact that Sicily, once the granary of Rome, should be so frequently afflicted with scarcity and famine, sought to investigate the causes of this great change. He recommended freedom of internal trade, but with regard to the exportation of corn, he thought it might be suspended at times by an act of government from prudential motives. 12, Saverio Scrofani, on the contrary, in a 'Memoria sulla *Libertà* del Commercio dei Grani della Sicilia,' published in 1795, advocated an entire and permanent freedom in the corn-trade, quoting the example of Tuscany, where that system had been in practice since 1767, and had been attended with the best results. 13, Maurizio Solera, a native of Piedmont, wrote, in French, 'Essai sur les Valeurs,' which he presented in 1786 to King Victor. He proposed an agricultural bank in order to make up for the scarcity of bullion. But his project was not carried into effect. 14, Lodovico Ricci, a native of Modena, was named, by the Duke Ercole III., member of a commission appointed to inquire into the charitable institutions of the town of Modena. Ricci was the reporter of the commission, and his Report was published and dedicated to the duke: 'Riforma degl'Istituti Pii della Città di Modena,' 1787. He was one of the first in Italy (Ortes and Genovesi had already expressed opinions similar to his) who censured indiscriminate charity as encouraging idleness and improvidence, and thus creating pauperism. Italy abounded at that time, more perhaps than any country in Europe, with charitable institutions. In Modena, which had in the time of Ricci a population of 40,000 inhabitants, there were 7000 destitute persons. Ricci demonstrated from historical facts that pauperism increases in proportion to the facility of obtaining relief. He censured legacies for portioning poor girls, and other premiums on marriage, and said that the increase of population should only be the result of labour and frugality, by which the means of subsistence are increased. He proposed that charitable institutions should be supported by private charity, and not by the government, which should not do more than establish workhouses to give employment to paupers and vagrants, instruct the poor classes, and endeavour to raise their moral condition. The advice of Ricci was acted upon by the government of Modena. 15, Giuseppe Palmieri, born in 1721, in the province of Lecce, in the kingdom of Naples, filled several offices in the administration of his country, and wrote observations on the tarif and on national wealth: 'Osservazioni sulle Tariffe con applicazione al Regno di Napoli,' and 'Sulla *Ricchezza* Nazionale.' In speaking of commerce, he says that a full and universal liberty would be the best system, but as this liberty is not admitted by any nation, the nation that should alone put it in practice might find it turn to its disadvantage, and its condition would be that of a lamb among wolves. He therefore advises not the prohibitive but the restrictive system, or in other words, a system of custom-house duties on the principle of reciprocity. 16, Count Mengotti of Feltra, in the Venetian state, wrote, in 1791, a book against the exclusive mercantile system, which he styled 'Il Colbertismo,' from the name of Colbert, the great patroniser of that system. This work was written in reply to a query proposed by the Economical Society of Florence, which was put in the following words: 'Whether in a state which, by its locality and the nature of its soil, is susceptible of increase of produce and population, it be most adviseable to favour manufactures by certain restrictions on the exportation of the raw materials, or to leave it an entire freedom?' Mengotti recommended perfect freedom of trade, and his book obtained the prize. It is one of the best written works of the Italian political economists. Mengotti, Beccaria, and Galiani are three writers who, by their style, have succeeded in enlivening an abstruse subject and making their dissertations entertaining as well as instructive. Mengotti wrote also a memoir, 'Sul Commercio dei Romani,' which obtained, in 1787, the prize from the Academy of Inscriptions and Belles

Lettres of Paris. Mengotti maintained, that until the first Punic war the Romans had no commerce in an extended sense; that from the first Punic war to the battle of Actium their commerce consisted in carrying home the spoils of other nations; that from Augustus to Constantine their trade was mainly passive and ruinous; they produced nothing, and bought foreign luxuries and even the necessaries of life with the money they extorted from the subject provinces, and at last they fell gradually again into poverty and barbarism.

The above are the principal Italian political economists of the eighteenth century. The complete collection of all the Italian writers on political economy was edited by Custodi, in 50 volumes, 8vo. Melzi, the vice-president of the Italian republic, supplied the author with the necessary funds for the undertaking. Custodi was afterwards made by Napoleon counsellor of state of the kingdom of Italy, baron, knight of the iron crown, and secretary of finance.

In England the science of political economy made a marked progress in the latter part of the eighteenth century through the exertions of Adam Smith, who is considered as the founder of the modern school. In 1776 Smith published his great work, with the modest title of 'An Enquiry into the Nature and Causes of the Wealth of Nations.' In the first book he treats of the division of labour and its wonderful effects, of the real and nominal price of commodities, the wages of labour, the profits of stock, and the rent of land. Book ii. treats of the nature, accumulation, and employment of stock or capital. Book iii. is in a great measure historical, and treats of the different progress of opulence in different nations. Book iv. is employed in discussing the various systems of political economy. Smith did not follow implicitly either the mercantile system or that of the economists; he showed, in opposition to the latter, that the labour of manufacturers and merchants is productive and is a source of wealth, but he at the same time considered agriculture as the most productive kind of labour, and the home trade as more productive than foreign trade. These positions have been combated by writers who have adopted many of his general views. On the subject of foreign trade modern writers on political economy are divided, some maintaining that all foreign trade is advantageous to a country precisely in the degree in which it is profitable to those who are engaged in it, and independently of war and peace and other national vicissitudes; whilst others contend that the immediate interest of the trader is not in all cases a criterion of the permanent national interest.

Adam Smith's doctrine of universal free trade has found many opponents, and is in fact still a theory, for it is not in practice in any country. His definition of productive and unproductive labour has been contradicted by Malthus, in his 'Principles of Political Economy,' and in France by Say and others. Smith considered commerce as an exchange between producers of various commodities, but not as a cause of fresh production by stimulating new wants in the producers. His doctrine of the 'natural rate of wages' has also been controverted. (McCulloch's 'edition' of Smith's 'Wealth of Nations,' with a *Biography of the Author, and Notes and Supplementary Dissertations*, by the editor.)

In 1798 Malthus published his 'Essay on the Principle of Population,' in which he demonstrated that 'an increase in the means of subsistence is the only sure criterion of a real permanent and beneficial increase in the numbers of any people.' He stated that the population never falls below the level of subsistence, but that it tends, on the contrary, always to exceed it, and is only kept down by moral or physical checks. A consequence of these positions is, that any artificial stimulus to the increase of population by premiums on marriage, laws against celibacy, &c., is injudicious. These inferences had been anticipated by the Italian political economists Ortes and Ricci.

In France, J. B. Say published, in 1802, 'Traité d'Economie Politique,' in which he expounded the principles of Adam Smith, adding many original and important illustrations, especially on the nature and causes of gluts resulting from over-production, which, he maintained, can only be partial and temporary, and can never occur in every species of commodity at once. Say has written several other works on political economy. Garnier also translated the work of Smith into French.

In 1815 appeared an 'Essay on the Application of Capital to Land,' by Mr. West, Oxford, 1815, and about the same time Malthus published 'An Enquiry into the Nature and Progress of Rent,' a subject which was afterwards investigated and expounded by Mr. Ricardo, in his 'Principles of Political Economy and Taxation,' published in 1817, and which is generally considered as the most important work on political economy since the time of Adam Smith. [RICARDO.]

Among other contemporary writers on political economy may be mentioned, in England, Mill [MILL], McCulloch, Senior, Tooke, and Torrens. In France, Sismondi has written several works on political economy: 'De la Richesse des Nations, ou Nouveaux Principes d'Economie Politique;' and 'Etudes sur l'Economie Politique,' which latter work contains many interesting facts, exhibited and commented upon in the usual attractive if not always strictly logical manner of the author. Ganilh published a general review of the principal systems of political economy: 'Des Systêmes d'Economie Politique, et de la Valeur comparative de leurs Doctrines,' 2 vols. 8vo., 1821, a work well deserving a perusal, being written in a temperate spirit and unassuming tone.

In Germany, Storch published, in French, 'Cours d'Economie Politique,' 6 vols., Petersburg, 1815, and also 'Betrachtungen über die Natur des Nationaleinkommens,' Halle, 1825. Schmalze wrote 'Staatswirthschaftslehre,' 2 vols., Berlin, 1818; and Jakob, 'Grundsätze der Nationalökonomie,' Halle, 1825.

The Spaniards had two writers on political economy towards the end of the last century, Ulloa and Ustariz. The latter wrote 'Teorica y Practica de Comercio y de Marina,' fol., Madrid, 1791.

Political economy has not been neglected in the United States of North America, but few works, we believe, have yet been produced that have attracted much attention in Europe. Tucker's 'Laws of Wages, Profits, and Rent investigated,' and his 'Theory of Money and Banks investigated,' are valuable contributions to the science.

In Italy, the principal writer of the present century on political economy is Melchiorre Gioia of Piacenza, who died in 1824. Gioia was a jurist, a moralist, and a politician, as well as a political economist, and a notice of his works and a short account of his life are given under his name. Here however we shall dwell at more length upon his great work on political economy, 'Nuovo Prospetto delle Scienze Economische,' 6 vols. 4to., Milan, 1815-17. Gioia quotes most of the writers, Italian and foreign, who had preceded him, and endeavours to condense their various systems and opinions into a series of principles with their legitimate deductions. He lays down the following objects of the science:—1, To diminish the labour and the time employed in the production, as well as to diminish the quantity of the raw elements employed; in short, to produce with as little labour, time, and cost as possible. 2, To increase the quantity, perfection, and durability of the things produced. 3, The means of obtaining the above results consist in power, which is increased by capital, machinery, credit, association, distribution of labour, in knowledge of the means to improve, and will or activity, which is strengthened by liberty, security, and enlightened opinion of the people in general. A great part of the work is in a tabular form, with quotations and original remarks. Speaking of the influence of the government on the production, distribution, and consumption of wealth, Gioia notes a number of cases in which that influence may be useful, and a number of others in which it is injurious. Under the first head he reckons the construction of good roads, the distribution of courts of justice in each district, to save time and expense to suitors; the establishment of public libraries, consisting of useful books, of collections of natural history, and of philosophical instruments, botanical gardens, &c.; the foundation of gratuitous elementary schools in every commune, and of schools of arts and trades in every town; freedom of the press; the sending well-informed travellers into foreign countries to examine and report the discoveries and improvements made in each. Among the cases in which the influence of the government is injurious, Gioia reckons—1, Too heavy taxation, which, by gradually diminishing the disposable capital, prevents its being employed in making improvements. 2, The grant of public money to monastic establishments. 3, The unequal distribution of public burthens. 4, The payment of the judges by fees on the causes which they decide, which is still the case in several countries of the Continent, instead of a fixed salary sufficient to place them above temptation. 5, The inculcation or toleration of popular superstition, false miracles, and impostors. 6, The tribunal of the Inquisition and other inquisitorial censorships, index of forbidden books, &c. Gioia is an advocate for large masses of property, large manufactories, and great commercial cities. His exposition of the advantages of large farms over small ones induced the government of Piedmont to repeal the decree by which the rice-grounds belonging to the crown or the communes were to be parcelled out into small holdings. Gioia gives the preference to arts over agriculture, and he is the only one among the Italian political economists who has established the principle of the 'association of labour' (as in the case of joint-stock companies) as an important source of wealth, and has descanted upon its advantages. Gioia wrote also his 'Filosofia della Statistica,' which may be considered as an appendage to his work on political economy. [GIOIA.]

The other Italian writers on political economy in the present century are, 1, Ressi, who in 1808 published a work 'Dell' Economia della Specie Umana,' 4 vols. 8vo.; 2, Carlo Bosellini of Modena, who published, in 1817, 'Nuovo Esame delle Sorgenti della Privata e Pubblica Ricchezza;' 3, Giuseppe Pecchio, who wrote, 1, 'Saggio Storico sull' Amministrazione Finanziera dell' ex-Regno d' Italia, dal 1802 al 1814,' London, 1826, in which he treated of various subjects connected with political economy; 2, 'L'Anno Mille Ottocento Ventisei dell' Inghilterra,' Lugano, 1827, in which he treats of the commercial crisis which took place in England in 1826, and of its causes, effects, and remedies; 3, 'Storia dell' Economia Pubblica in Italia,' Lugano, 1829, a work to which the writer of this article is mainly indebted for his account of the Italian writers on political economy. At the end of the work Pecchio draws a parallel between the Italian and the English economists, from which we give the following extract, without any opinion on the correctness of all the author's views:—'The principal difference between the English and the Italian writers consists in the definition of the science and the manner in which they treat it. The English make political economy a science distinct from all others, the science of enriching nations; the Italians consider it as a complex science, and they treat it in connection with morality, civil administration, and general happiness. The English, being intent upon the object of wealth, approve of large divisions of property, and consequently of entails, because large properties afford a greater net profit in the shape of rent, without concerning themselves with the political and moral consequences of this mode of distribution. The English encourage a manufacturing population, because it increases the wealth of the country, without heeding the deterioration of the vigour and health of the people in crowded and heated work-rooms; they favour the use of machinery, because they produce at a much less cost than manual labour, without reflecting on the danger of over-production, and of the sudden stagnations of trade, by which thousands of workmen are thrown into distress. They look upon the workman himself as a productive machine, condemned to a labour, often excessive, imprisoned in sultry cotton-factories, or buried many fathoms deep in the bowels of the earth, to extract coal, tin, or iron. And if they recommend that the workman be well fed, this is in order that he may work harder and produce the more, a species of philanthropy similar to that of the post-master, who feeds his horses well in order that they may do most work. Some of the English seem to wish to transform the whole agricultural population into mechanics, and to work even the fields by means of machinery, without reflecting that by so doing they would substitute an emaciated, weak, and short-lived population for one vigorous and hale. Is wealth the only thing desirable? But supposing that it were so, let us reflect that the increase of wealth thus produced is not subdivided among those who labour; that they only get a bare subsistence, and all the rest of the profit is accumulated in a few hands. . . . . . The Italian writers, on the contrary, consider the science of political economy in all its relations to society; they do not seek wealth only, but the welfare of the greatest possible number of individuals. They consider every principle, every law, under several aspects, and with a view to its consequences. If they treat of the corn-trade, they go back to the origin of the right of property, and end with the consideration of the question whether it be good policy to let the subsistence of a whole country depend on foreign importation, which may be suddenly stopped by various accidents. If they treat of the division of property, they investigate the influence of the law of primogeniture on public morals and domestic harmony. In discussing the subject of the greatest produce of land, they give the preference to the subdivision of land among many proprietors, because it feeds a more numerous, healthy, and peaceful population. A fact or a measure appears very different when considered merely in an economical point of view, from what it shows itself when considered in both a political and economical aspect. For instance, during the discussion concerning the liberty of the press in France in 1827, an English economist would merely have observed that the suspension of that liberty would throw out of occupation about 100,000 individuals, and withdraw about two millions sterling a year from circulation. But was not the political evil resulting from that suspension incomparably greater?'

Perhaps few English writers on political economy will admit that this is an accurate statement of their opinions and of the objects of the science as they conceive them. They would also contend that the objects of the science as conceived by the Italian economists are too numerous and too vague to allow of any scientific treatment, and that subjects are blended together by the Italian writers which are capable of being separated and of being confined within distinct and definite limits. Such an objection to the system of the Italian economists is well founded; and the objects of the English economists may be completely defended if their views are simply limited to investigating the elements on which depend the actual production, distribution, and accumulation of wealth in any given community at any given time. This is a field of inquiry sufficiently extensive, and when it has been adequately examined, and not before, we can pass from the determination of what is to what ought to be any one of those elements on which national wealth depends. It would seem almost superfluous to observe that in determining what are the elements of the actual production of a nation, all the elements must be ascertained; the whole condition of the people must therefore be ascertained, that is, the whole political system must be examined, in order to ascertain what it is, and the state of all the several classes of the community must be ascertained; every law that interferes with a man's actions must be examined, and every restraint that is laid on the disposal of his property. But such an inquiry would be infinite, and yet such an inquiry is necessary in order to ascertain what *is*, and it is quite a distinct matter from determining what *should* be. It follows from these remarks that the English writers have conceived the science in a way much more limited but better defined than the Italian, and yet that even the English writers very inadequately investigate any one branch of political economy, even as they conceive it. Still their inquiries on any given branch of the subject may terminate in a result approaching to the truth, and such a result may be capable of a practical application.

A distinguished English economist has at the end of his work an observation which coincides with some of those of Pecchio. Speaking of those injudicious mercantile regulations which have been long established, and, although found to be pernicious, cannot be removed without producing a greater evil for an interval of considerable length, Malthus goes on to say, 'Theoretical writers are too apt in their calculations to overlook these intervals, but eight or ten years, recurring not unfrequently, are serious spaces in human life. They amount to a serious sum of happiness or misery, according as they are prosperous or adverse, and leave the country in a very different state at their termination. In prosperous times, the mercantile classes often realise fortunes, which go far towards securing them against the future; but unfortunately the working classes, though they share in the general prosperity, do not share so largely as in the general adversity. They may suffer the greatest distress in a period of low wages, but cannot be adequately compensated by a period of high wages. To them, fluctuations must always bring more evil than good; and with a view to the happiness of the great mass of society, it should be our object, as far as possible, to maintain peace and an equable expenditure.' (Malthus, *Principles of Political Economy*, the last paragraph.)

POLIZIA'NO, or POLITIA'NUS, ANGELO, born at Montepulciano in Tuscany, in 1454, was the son of Benedetto Ambrogini, a doctor of law. In after-life he dropped his paternal name, and assumed that of Poliziano, from his native town Mons Politianus. Lorenzo de Medici took care of his education, placed him under good preceptors, and provided for all his wants. He afterwards entered into clerical orders, took his degree of doctor of law, and was made a canon of the cathedral of Florence. He was entrusted by Lorenzo with the education of his children, as well as with the care of his library and collection of antiquities, and he was his guest and companion for the remainder of his life. Poliziano had studied Latin under Cristoforo Landino, Greek under Andronicus of Thessalonica, and philosophy under Ficino and Argyropulus of Constantinople. He was afterwards appointed professor of Latin and Greek at Florence, a chair which he filled with great reputation. He wrote scholia and notes to many antient authors, Ovid, Catullus, Statius, Suetonius, Pliny the Younger, and the 'Scriptores Historiæ Augustæ;' he translated into Latin the history of Herodian, the manual of Epictetus, the aphorisms of Hippocrates, some dialogues of Plato, and other works from the Greek. The 'Miscellanea' of Poliziano, published at Florence, in 1489, consist chiefly of observations he had made on the antient authors, which he arranged for the press at the request of Lorenzo. Merula made an attempt to depreciate this work, which led to an angry controversy between the two scholars, in the midst of which Merula died. Politianus had also a violent controversy with Bartolomeo Scala, in which the two disputants abused each other in Latin, according to the custom of scholars in those times.

Poliziano was conceited and vain, and very irritable, and his temper led him into an unbecoming altercation with Madonna Clarice, Lorenzo's wife, because she interfered in the education of her children, a thing which Poliziano seemed to think preposterous in a woman; and at last his behaviour to her was so impertinent that she turned him out of her house in the country, and she wrote to her husband at Florence to inform him of what she had done. Lorenzo, perceiving that a reconciliation between the offended woman and the irascible scholar was impracticable, gave Poliziano apartments in one of his houses at Fiesole, where he wrote his Latin poem 'Rusticus.' During Lorenzo's last illness, Poliziano attended the death-bed of his patron, who gave him tokens of his lasting affection. Poliziano wrote an affecting monody on Lorenzo's death, and not long after died himself, in September, 1494, at the age of forty, and was buried in the church of San Marco, agreeably to his request. Jovius and others have told several improbable stories as to the immediate cause of his death. (Corniani, *Secoli della Letteratura Italiana;* Roscoe's *Life of Lorenzo de' Medici.*)

The other works of Poliziano are—1, 'Panepistemon,' in which he describes a category of all the various branches of human knowledge; 2, 'Sylvæ,' odes, epigrams, and other short Latin poems; 3, his Italian poetry, especially his poem on the Giostra, or tournament of Giuliano de' Medici, which is much admired. He also wrote the 'Orfeo,' which is considered as the earliest specimen of the opera, or Italian musical drama. His Latin works, including 12 books of Letters, were published at Paris, fol., 1512.

POLLARDS are trees which have had their tops repeatedly cut off for the sake of the faggot-wood, which is used for burning and heating bakers' ovens. The appearance of an old pollard may, in particular situations, be thought picturesque, but nothing can be more unsightly in a landscape than rows of pollards bordering every inclosure, as is seen in some countries. It is only in the case of a few trees of quick growth, such as willows and poplars, that there is a profit in making pollards of them. To have oak, ash, and elm polled, which if left to grow would in time produce valuable timber, is a very great loss to the proprietor of the land, and but little profit to the tenant. Supposing an oak polled when twenty years old, and lopped every ten years after, there will be seven loppings only, worth a few shillings each, in the first century; whereas the oak, if left to acquire the age of one hundred years, would have afforded excellent timber for ship-building, and produced five times as much money as all the loppings put together. It is usual to allow tenants to lop such trees as have been lopped before, but it would be much more profitable to all parties if the pollards were all rooted up, and a few timber-trees planted at considerable distances from each other in the hedgerows. Where wood is required for fuel, it is better to plant a good coppice interspersed with timber-trees; and if this be done judiciously on good sound land, the quantity taken from the farm for this purpose will be as profitable as if it had been kept in cultivation. Trees are often planted in soils which are not worth cultivating; and hence the profit from a good coppice is usually underrated; but if the damage done to the land by the roots and shade of trees be taken into the account, it will be found that it is more profitable to have the wood growing by itself.

On the margin of low rivers running through marshy grounds, it may be profitable to plant willows, poplars, and other soft-wooded and rapidly-growing trees, in order to lop them at stated intervals. Their timber would be of little value if they were left in their natural state; but being lopped every seventh year, they produce rods and faggots, which are readily disposed of. Hence the common saying that 'a willow will buy a horse before an oak will buy the saddle.'

To manage pollards advantageously the head of the tree should be cut off at a moderate height while the tree is young, and the shoots which spring from the crown must be frequently cut off before they begin to branch out. Thus a good head is formed, throwing out many shoots, which may then be left to grow till they are of a useful size. The willow takes root so readily, that if a branch twelve or fourteen feet long is put two feet into the ground, it will grow, and form a tree at once, which after a few loppings will become a pollard.

If the appearance of rows of pollards is unsightly, the cutting the side branches of trees in hedgerows, leaving only a little tuft at the top, is much worse. No branch above ten feet from the ground should ever be permitted to be cut by a tenant, nor the top of any tree to be cut off in order to make a pollard of it, and a clause to that effect, with a severe penalty, should be inserted in every lease.

POLLEN is the organic matter by which impregnation is effected in the vegetable kingdom. It is to the naked eye a very fine powder, and is usually enclosed in the cells of the anther; but examined with the microscope, it is found to consist of hollow cases, usually spheroidal, filled with a fluid in which are suspended drops of oil from the 20,000th to the 30,000th of an inch in diameter, and grains of starch five or six times as large. The shell, or *extine*, of these cases is lined in most instances with a delicate membrane, or *intine*, which, when the pollen falls upon the stigma, protrudes beyond the extine at some point or points of the surface, and lengthens into a tube of extreme tenuity, which penetrates the stigmatic tissue, and is called the pollen-tube. This emission of a tube takes place in from six to twenty-four hours after contact between the pollen and the lubricated face of the stigma. The pollen-tubes continue to lengthen until they reach the foramen of the ovule, which they enter, placing themselves in communication with the apex of the nucleus of the ovule, where eventually the vegetable embryo makes its appearance. The contents of the original case of the pollen are emptied into the tube, where they disappear.

The pollen grains, although usually spheroidal, also assume other figures; in some plants they are depressed, in others cylindrical, in others triangular; in most instances they are simple; but in Inja, Acacia, and the allied genera, and in Orchidaceæ, there are several grains adhering in definite or indefinite numbers. We generally find pollen lying loosely in the cells of the anthers; but in the Asclepiadaceous order the grains are enclosed in a bag consisting of the lining of the anther-cell.

The minute oily and amylaceous molecular matter that is suspended in the fluid with which it has been stated that the pollen grains are filled, moves actively, each particle upon its own axis, and this has given rise to the idea that these molecules were of an animalcular nature. They appear however to be in no respect different from similar matter in other parts of the vegetable fabric, except in the minuteness of their division.

(Lindley's *Introduction to Botany*, ed. 3, book i., cap. 2; Fritzsche, *Ueber den Pollen*, 4to., 1837, St. Petersburg.)

POLLENZA. [MALLORCA.]

PO'LLIA, a genus established by Mr. J. E. Gray for certain species of Lamarck's *Canalifera*. The shells which Mr. Gray proposes to comprehend under this generic appellation differ from *Triton* in the absence of external varices, and from *Purpura* in the presence of crenulations on the columella. There are also crenulations on the outer lip.

Example, *Pollia articulata* (*Fusus articulatus*, Lam.).

POLLI'CIPES. [Cirripeda, vol. vii., p. 208.]

PO'LLIO, CAIUS ASI'NIUS, was born B.C. 76, and appears to have been descended from a family of no great consequence. (Vell. Pater., ii. 128.) He is called by Catullus a Marrucinian, and was probably a descendant of Herius Asinius, who commanded the Marrucini in the Marsic war, and was killed in battle. (Livy, *Epit.* 73.)

We first read of Pollio as the public accuser of C. Cato (B.C. 54), who was acquitted through the influence of Pompey. (Tac., *Dial. de Orat.*, 34; Cic. *ad Att.*, iv. 15, 16, 17.) On the breaking out of the civil war between Cæsar and Pompey, Pollio took the side of the former, and accompanied him in the passage of the Rubicon. (Plut., *Cæs.*, 32.) He was afterwards sent by Cæsar, under the command of Curio, to Sicily and Africa, and after the defeat of the latter by Juba, he escaped with a few of the forces to the neighbourhood of Utica, and thence passed over to Italy to join Cæsar. (Appian, *De Bell. Civ.*, i. 45, 46.) He was present at the battle of Pharsalia (Plut., *Pomp.*, 72), and two years afterwards (B.C. 46) he accompanied Cæsar into Africa and Spain, and on the return of Cæsar to Italy appears to have been made one of the fourteen prætors who were appointed by Cæsar at that time. (Drumann, *Geschichte Roms.*, vol. ii., p. 6.) Pollio probably did not return to Italy with Cæsar, since we find him in the following year (B.C. 45) acting as Cæsar's legatus in Spain, where he carried on the war against Sextus Pompeius. (Dio., xlv. 10; Vell. Pater., ii. 73.) On the death of Cæsar (B.C. 44), he appears, if his letters to Cicero contain his real sentiments (*Ad Fam.*, x. 31, 32, 33), to have been inclined to support the senatorial party; but after Octavianus united himself to Antony, Pollio no longer hesitated to support the latter. He soon afterwards received from Antony the government of the province of Gallia Transpadana, and was nominated by the triumvirs as one of the consuls for B.C. 40. During his consulship, Virgil addressed to him the fourth Eclogue. In the following year Pollio was sent by Antony against the Dalmatians, whom he conquered, and obtained the honour of a triumph. (Dio., xlviii. 41; Appian, *De Bell. Civ.*, v. 75; *Fast. Capitol.*; Hor., *Carm.* ii. 1, 15, 16.) He appears to have retired about this time from public affairs. He took no part in the war between Augustus and Antony, and when asked by the former to accompany him to the Actian war, he declined doing so on account of his early friendship with Antony. He died A.D. 4, at his Tusculan villa. (Clinton's *Fast. Hell.*)

Pollio was a great patron of learning and the fine arts, and was also the author of several works which were greatly praised by his contemporaries. He appears to have possessed a fine collection of antient statues. (Pliny, *Hist. Nat.*, xxxvi. 4, §6.) He founded the first public library at Rome, in the Atrium Libertatis on Mount Aventine. (Isid., *Orig.*, vi. 5; Ovid, *Trist.*, iii. 1, 71; Mart., *Epig.* xii. 3, 5.) He lived on intimate terms with Virgil and Horace, the latter of whom has dedicated to him the first ode of his second book. He was a poet, an orator, and an historian, and his poetry, and more especially his tragedies, if we can trust the suspicious testimony of Virgil (*Ecl.* iii. 86; viii. 10) and Horace (*Carm.* ii. 1, 9-12; *Sat.* i. 10, 42), were far above the common standard. His history of the civil wars, which was comprised in seventeen books, is quoted or referred to by several of the antient writers. (Plut., *Cæs.*, 46; Suet., *Cæs.*, 30; Appian, ii. 82; Tac., *Ann.*, iv. 34.) His orations are frequently spoken of by Quintilian, but his style is condemned as deficient in clearness and ease. (Quint., *Inst. Orat.*, x. 1; compare Tac., *Dial. de Orat.*, 21; Senec., *Ep.* 16.) Pollio also appears to have written criticisms on the works of most of his contemporaries, and to have attacked them in a very severe manner. He found great fault with the orations of Cicero (Quint., *Inst. Orat.*, xii. 1), and said that the 'Commentaries' of Cæsar were deficient in historical accuracy. (Suet., *Cæs.*, 56.) He remarked a kind of Patavinity in the style of Livy (Quint., *Inst. Orat.*, viii. 1; i. 5), and appears to have censured Sallust for the use of antient words and modes of expression. (Suet., *De Clar. Gram.*, c. 10.) All his writings are lost, with the exception of a few letters to Cicero.

(Thorbecke, *Commentatio de C. Asinii Pollionis Vita et Scriptis*, Leyden, 1820, 8vo.; Eckhard, *Commentatio de C. Asinio iniquo opt. Latin. auct. censore*, Jen., 1743; Meyer, *Oratorum Romanorum Fragmenta*, p. 211, Zürich, 1832; Orelli, *Onomasticon Tullianum*, vol. ii., p. 76; Drumann, *Geschichte Roms.*, vol. ii., pp. 1-12.)

PO'LLIO, TREBE'LLIUS. [Augusta Historia.]

POLLONTES, De Montfort's name for a genus of microscopic *Foraminifera*. [Foraminifera, vol. x., p. 348.]

POLLUX, JU'LIUS, whose real name is Polydeuces (Πολυδεύκης), a celebrated grammarian and teacher of rhetoric, was born at Naucratis in Egypt, about the middle of the second century of the Christian æra. He was well educated by his father, and afterwards received instruction from Adrian the sophist. He was a favourite with M. Aurelius and his son Commodus, by the latter of whom he was appointed teacher of rhetoric at Athens. He died at the age of fifty-eight.

Pollux wrote several works, all of which have been lost except his 'Onomasticon' (Ὀνομαστικὸν). The 'Onomasticon,' or Dictionary of Greek words, is not arranged in alphabetical order, but is divided according to subjects, and gives the different Greek words which belong to each subject. Thus all the words relating to agriculture are classed by themselves, and in the same way all words belonging to ships, carriages, houses, &c. are treated of separately. The work is not merely a dry list of words, but contains numerous quotations from the different Greek writers, and supplies us with much information relating to antiquity, of which we must otherwise have been ignorant. It is divided into ten books, and was dedicated to Commodus during the life-time of Aurelius. The first edition was published at Venice, in 1502. The best editions are by Hemsterhusius, who has annexed a valuable Commentary, Amst., 1706, 2 vols. folio, and Dindorf, Leipzig, 1824, 5 vols. 8vo.

There was also another writer of the name of Julius Pollux, who lived in the 10th or 11th century of the Christian æra, and wrote a 'Chronicle,' or 'Universal History' from the foundation of the world to the time of Valens. This work, which has come down to us, has been edited by Bianconi, Bonn, 1779, folio; and Hardt, Munich and Leipzig, 1792, 8vo.

POLLUX. [Gemini.]

POLO, MARCO, the son of a Venetian merchant named Niccolo, who set off from Venice with his brother, in the year 1250, for Constantinople, whence, having purchased valuable jewels and precious stones, he sailed up the Euxine to La Tana at the mouth of the Tanais. From La Tana he proceeded inland to Bulgar on the Volga, the residence of Barga, the Khan of the Western Tartars, or of Kaptchak, who purchased his wares at a very liberal price. From the residence of the Khan the two Venetian travellers proceeded round the north side of the Caspian Sea to Bokhara, where they arrived in the year 1261. They remained three years at Bokhara, during which time they applied themselves to the study of the Mongol language, and in 1264 they met an ambassador sent by Hulaku, grandson of Gengis, the ruler of Persia, to Kublai, the great khan of the Mongols, or Khalkhas, who ruled over Tartary and China, and who resided at Kemenfu in Chinese Tartary. The two Venetians agreed to accompany the ambassador, and arrived at Kemenfu in the following year, 1265. Kublai received them well, and wishing to establish a connection with the Western world, of which he had only a confused knowledge, he commissioned the two brothers Polo to proceed as his envoys to the pontiff of the Christians, requesting him, in a letter, to send him a hundred men, learned in the various sciences and arts, to instruct his people. The Polo, furnished with Kublai's credentials, returned towards the west, and arrived at the coast of Syria, from whence they sailed for Venice, which they reached in 1269, after an absence of nineteen years. Niccolo found his wife dead, but she had left him a son, Marco, who was born soon after his departure.

Owing to the death of Pope Clement IV. and the long interregnum which followed, the two Polo could not execute Kublai Khan's commission, and they determined on returning to Tartary, and taking young Marco with them. But after they had landed on the coast of Syria they heard of the election of Gregory X., who was then at Ptolemais, whither they repaired, and conferred with the new pope on the subject of their mission. Gregory appointed two Dominican friars to accompany them. They set out for the interior in 1272, but the two friars, being frightened at the war which was then raging in Asia between Sultan Bibars the Mameluke, and the king of Armenia, declined prosecuting their journey, and the three Venetians proceeded alone through the regions of Central Asia. They reached the court and camp of Kublai Khan in 1275, where they met with the most favourable reception. Kublai was especially pleased with Marco, and he entrusted him with missions to various parts of China and India. Marco Polo was the first European who visited China Proper: he made memoranda of what he saw himself, and eagerly collected all the information that he could obtain about those parts which he did not visit. In reading his narrative therefore a distinction ought to be made between his own observations and those which he derived from the report of others. After a lapse of several years, an ambassador arrived at the court of Kublai Khan from Argon, the ruler of Persia, who asked in marriage a princess of Kublai's family. Kublai chose a princess named Cagatin, and prepared to send her to Persia by sea, with several ambassadors and a large retinue. The three Polo obtained, though not without difficulty, permission to form part of the escort. They set out in 1291, traversed China, embarked on the coast of Fo-kien, which lies opposite to the island of Formosa, and thence they proceeded through the straits of Malacca to the island of Ceylon, and from thence to Ormuz in the Persian Gulf. On landing they proceeded to Teheran, where they found that Argon was dead, and some time after, hearing also the news of the death of Kublai, the three Venetians thought of returning home, and at last arrived at Venice in the year 1295. War was then raging between Venice and Genoa. Marco Polo obtained the command of a galley forming part of the squadron commanded by Andrea Dandolo, which was defeated by the Genoese under Lamba Doria, off the island of Curzola in the Adriatic. Marco Polo was carried prisoner to Genoa. In his captivity he used to relate his adventures, and was eagerly listened to. He sent to Venice for his memoranda, which he had taken down in his travels, and having made acquaintance with a fellow-prisoner of the name of Rustichello, a native of Pisa, who had been taken, with thousands of his countrymen, in the battle of Meloria, he dictated to him the narrative of his travels, and lent the MS. to read to the curious.

After peace was made between Genoa and Venice, Marco Polo returned home. His father, Niccolo, was still living, but he died in 1316. Of the latter period of his son Marco's life nothing more is known, except that after his return to Venice he applied himself to correct and improve the text of his narrative, of which it appears that a French translation was made under his direction, and given by him to Thibault, lord of Cepoy, who was appointed by Catherine Courtenay her vicar-general in the possessions which still remained to the Latins in the East. The work is entitled, 'Marco Polo, delle Meraviglie del Mondo da lui descritte;' and in other copies, 'Delle Cose dei Tartari e dell' Indie Orientali;' and in others, 'Il Milione di Marco Polo.' It was inserted by Ramusio, in his 'Raccolta di Navigazioni e Viaggi,' 3 vols. fol., Venice, 1550-59. But the best edition of Marco Polo is that by Count Baldelli, 4 vols. 4to., Florence, 1827, entitled 'Il Milione di Messer Marco Polo Veneziano,' with notes and illustrations, and a biography of Polo: it is also accompanied by a history of the intercourse between Europe and Asia in the middle ages, with the following title:—'Storia delle Relazioni Vicendevoli dell' Europa e dell' Asia dalla Decadenza di Roma fino alla Distruzione del Califfato.' Count Baldelli has adopted as his text a MS. written by Michele Ormanni, at the beginning of the fourteenth century, in Marco Polo's lifetime. Baldelli's work is illustrated by a map of Africa, drawn in 1351, and by another map with all the itineraries of the three Polo traced upon it. It is altogether a work of great research and very interesting. For a long time Polo was considered a liar and not worthy of confidence. But more accurate investigations have demonstrated his veracity in relating what he saw himself. Klaproth, in several articles in the French 'Asiatic Journal,' has proved Polo's accuracy with regard to China. Polo's narrative was of great use to the pope's missionaries and the Venetian travellers who followed his track in the eastern parts of Asia, and the Chinese and Arabian maps which he brought home encouraged and assisted the Portuguese navigators in finding a passage to India round the Cape of Good Hope. Marsden has published a translation of Marco Polo's narrative, accompanied by a commentary.

Polo's account of the court of Kublai Khan gives us a much higher opinion of the social state of the Eastern Tartars in his time than is generally entertained. It appears that the Mongols had shared largely in the civilization of China, and had made considerable progress in the arts and sciences.

POLTA'VA, or PULTAVA, is a government in European Russia, lying between 48° 48′ and 51° 4′ N. lat., and between 30° 25′ and 36° E. long. It is bounded on the north-west by Tschernigow, at the most northerly point by Kursk, on the north-east by the Slobode of the Ukraine, on the south-east by Ekaterinoslaw, on the south-west by Kherson, and on the west by Kiew. It is impossible to state the area in a satisfactory manner: according to the estimates made in 1804, from the great map of Russia, it was stated at 21,315 square miles; according to Reymann's map and to Schubert, in 1835, it is 17,850 square miles; Wichmann makes it only 15,500 square miles: Schmidtlin (1835) asserts that the first estimate is certainly too large, and seems to prefer that of 17,850 square miles; yet Hörschelmann (1833) and the 'Weimar Almanac for 1840' give the largest estimate. The statements of the population are equally discordant. It appears to have been ascertained, in 1796, to amount to 1,350,726. Hassel, adding the probable annual increase during twenty-four years, gives 1,933,000 as the amount in 1820. Subsequent writers, at much later dates, make the amount less: thus Köppen, in 1838, makes it only 1,621,000; but Schmidtlin, in 1835, insists that it cannot be less than 1,900,000; Hörschelmann (1833) has 1,955,000; and the 'Weimar Almanac for 1840,' quoting Bulgarin, has 1,967,000.

Face of the Country; Soil; and Climate.—This government is one continuous plain, with scarcely any irregularities of surface, except the elevated banks of the Dnieper and some other rivers. The soil consists of a thick layer of black mould on a basis of clay and sand; it is either arable land or rich meadows; the forests are few and inconsiderable. The heaths are covered with nutritious grass; those where furze and broom predominate are common only in the south-east part of the government. The principal river, towards which the whole country slopes, is the Dnieper, which however only flows along the western frontier, towards Kiew, Kherson, and Ekaterinoslaw, and is everywhere navigable. Its chief tributaries are the Trubesch and the Sula, with the Udai coming from Tschernigow, the Psiol and the Worsikla from the Ukraine, and the Orel, which forms for some distance the frontier towards Ekaterinoslaw. The Sula and Psiol are navigable in the spring, are free from rocks, and flow through a rich country. There is no considerable lake in this government. The climate is mild; in winter however, when the cold north winds sweep over the open plains, the cold is severe. The summer is very hot. Little rain falls in the summer.

Of all the provinces of Little Russia, Poltava is the most fertile and the best cultivated. The soil is so rich that it yields ample crops without manure, and it would produce much more if a better system of cultivation and a proper rotation of crops were adopted. The grains chiefly cultivated are rye, barley, and oats, then wheat, buckwheat, Egyptian barley, and millet. The inhabitants cultivate also peas, lentils, rapeseed, linseed, and tobacco. All kinds of vegetables known in Russia thrive, even the more delicate kinds, such as asparagus, artichokes, and cauliflowers; fruits of all kinds abound, but not of the best quality; from cherries, plums, melons, and berries of various kinds, liqueurs are manufactured, and excellent preserves made. The vine might thrive, if there were any mountains to afford protection against the cold north wind. The government is not wholly without forests, but the farther we go to the south-east the more bare is the country, and the eastern circles have hardly any wood but that of their fruit-trees. On the Dnieper the inhabitants use the reeds growing on its banks for thatch and for fuel; in the interior they burn cow-dung and straw.

The steppes are covered with rich pastures, and the climate, says Hassel, is so favourable that the cattle remain in the open air all the year round. In these steppes the magnificent ox of the Ukraine attains its extraordinary size; horses are bred in great numbers; and the Russian sheep appear in large flocks. Within the last twenty-five or thirty years the breed of sheep has been greatly improved by the importation of Merinos; even previous to this, most of the manufacturers at Moscow were supplied with wool from the Ukraine. The breeding of swine is not much attended to; bees are common, and many farmers have above 100 hives. Common poultry is abundant; there are likewise blue Caspian or Chinese geese and Persian ducks. Hares and partridges are abundant, and, on the banks of the Dnieper, Numidian cranes (*Ardea virgo*), swans, pelicans, red ducks, water-hens, and snipes of all kinds. Though the Dnieper and other rivers abound in fish, the Russians consume so much in their numerous fasts, that it is necessary to import large quantities. The Dnieper furnishes the *Silurus Glanis*, Linn., of the bladders of which glue is made, and the dried skin is used as a substitute for window-glass. The country is periodically infested by immense swarms of locusts; gad-flies and a kind of musquito are very troublesome. There is potters' clay, brick clay, lime, chalk, and saltpetre.

Though this fruitful province is so well peopled, very few hands are employed in manufactures. The inhabitants indeed manufacture articles of various kinds for domestic use, and it is only of their fine liqueurs and preserved fruits that there is a surplus for exportation. The distilleries of brandy are considerable. The Sula and Psiol are navigable only in the spring; the Dnieper only touches the frontier, and is scarcely navigable beyond the limits of the government on account of its cataracts. This want of inland communication lessens the value of the produce, and in former times the farmers frequently suffered their crops to rot on the ground.* A great change has however taken place within the last twenty years, because Odessa draws a great part of its supplies from this government, the prosperity of which is progressively and rapidly increasing. The chief articles of export are corn, flour, groats, brandy, linseed oil, hemp, flax, tobacco, honey, wax, wool, tallow, butter, horses, oxen, preserved fruit, and liqueurs.

The most important trading towns are Poltava, Krementschuk, and Romny. There are in all only twenty-two towns in this government, of which fifteen are the capitals of the fifteen circles: but the number of villages is not known; they are however very numerous, and though, for want of timber, the buildings are mostly of clay, they are kept very clean, both within and without; and the villages, being surrounded with orchards and gardens, have a very cheerful appearance.

The majority of the inhabitants are Little Russians, mixed however with a considerable number of Great Russians and some German colonists. At Krementschuk there are some Greeks and Armenians, and a few Jews. The Greek clergy are under the bishop of Poltava and Pereaslawl, who has 983 parishes in his diocese. Education is at a very low ebb; according to Schmidtlin, 'there were, in 1832, only twenty schools (including one gymnasium), with 110 masters and 1823 pupils, of whom only thirty-nine were girls. To these must be added five schools, under the clergy, with eighteen masters and 1044 pupils: in all 2867; that is, one pupil out of 662 inhabitants. There is but one printing-office in the whole government.'

The southern frontier was formerly defended by a chain of twenty small fortresses, garrisoned by twenty regiments, called the Line of the Ukraine, which extended from the Dnieper to the Donetz; but this defence being long since useless, the garrisons have been withdrawn, and the fortresses suffered to fall to ruins; of many of them not a trace remains.

Poltava, the capital of the government, is situated in 49° 30′ N. lat. and 34° 15′ E. long., near the confluence of the rivers Poltawka and Worskla. It is built of wood, but the streets are wide and straight, and in the centre there is a good square surrounded with stone houses, and in the middle of it a handsome monument, of granite, in honour of Peter the Great. It is surrounded by a rampart, and there was formerly, says Schmidtlin, a citadel in the centre, built on a small eminence. Hörschelmann however says 'there is, in the middle of the town, an earthen fort, with batteries.' This town made a vigorous resistance to Charles XII., which led to the battle of Poltava, in which the Swedes were totally defeated, and Charles obliged to seek refuge in Turkey. A fine obelisk is erected on the field of battle, near which divine service is performed annually in commemoration of this victory. Poltava has ten churches (including the cathedral), a convent, a gymnasium, and a school. The inhabitants, 10,000 in number, have considerable distilleries and tanneries, and carry on an extensive trade in the produce of the country. The town is surrounded with vast cherry-orchards, from the fruit of which a very strong ardent spirit is distilled. There are four annual fairs. In the vicinity there are extensive saltpetre works, and the village of Reschetilowka, celebrated for its fine breed of sheep.

The following are the other chief towns: Mirgorod, on the Khorol, has 7400 inhabitants, and holds great horse-fairs. Lubuyg, on the Sula, has 6000 inhabitants. Pereaslawl, at the confluence of the Alta and the Trubesch, has a great trade in cattle and corn, and 8000 inhabitants. Krementschuk, a well-built town, at the confluence of the Kaganlik and the Dnieper, has a considerable trade and a wool-fair, and 8000 inhabitants. Its liqueurs and preserved fruits are very excellent. Romny, or Romen, on the Sula, a small town, with not above 2000 inhabitants, is celebrated for its fairs, especially that held at the Ascension, where goods to the amount of more than fifteen millions of rubles are offered for sale.

(Hassel; Cannabich; Stein; Schmidtlin.)

POLYADE'LPHIA, the name given by Linnæus to the eighteenth class of his sexual system. It was so named from *πολύς*, 'many,' and *ἀδελφός*, a 'brother,' in allusion to the stamens being collected into several parcels. In consequence however of the difficulty of ascertaining this point of structure in many cases, the class has been suppressed by some Linnean botanists.

POLYÆNUS was the author of a work called *Στρατηγηματικά*, or *Στρατηγήματα* (Stratagems of War), in eight books. He lived about the middle of the second century A.D. Respecting the circumstances of his life we know nothing except what he himself tells us in the introduction to his work, which he dedicated to the emperors M. Aurelius Antoninus and L. Verus. He there says that he was a native of Macedonia, and at an advanced age when he wrote his book. It contains an account of the various stratagems of war from the remotest times down to his own, and is a compilation made without any taste or judgment: it is however not confined to real stratagems; it contains sayings, apophthegms, and many other things which are anything but what the title-page promises. But as the author collected his materials from sources which are now lost, we have reason to be grateful for the preservation of many facts which would otherwise be unknown to us, though it is evident in many passages that Polyænus must have misunderstood or misrepresented his authorities. His style is rhetorical, but notwithstanding its numerous solecisms and errors, it is better than that of many other writers of the same age. The first edition of Polyænus was published by Casaubonus at Lyons, in 1589; another by Maasvicius, with a Latin translation, appeared at Leyden, in 1690. A reprint of the latter, with an improved Latin translation, was published by Mursinna, at Berlin, in 1756. The best edition however is that by Coraes, Paris, 1809. Polyænus has been translated into English by R. Shepherd, London, 1793, 4to., and into German by Seybold, in 2 vols., Frankfort, 1793 and 1794.

POLYA'NDRIA, the name given by Linnæus to the fourteenth class of his sexual system. Although the name means literally many stamens or males, yet it is applied, in a restricted sense, to those plants only which have many stamens arising immediately from below the ovary.

POLYA'NTHES TUBERO'SA, or the Tuberose (a corruption of *Plante Tubéreuse*), is a tuberous-rooted plant highly prized for the delicious fragrance of its flowers, on which account it is cultivated in the warmer parts of both the old and new world. Doubts are entertained regarding its native country. It appears to have been first seen in Europe by Clusius, who received it from Simon de Tovar as an Indian plant, but whether from the East or the West is unknown. It is extensively cultivated in the East Indies, whence it has been supposed to be an Asiatic plant; but no traveller has found it wild there, and it has no Sanscrit name. It is therefore more probable that it is of South American origin, for it is equally common there in cultivation; and, as Sir James Smith has rightly observed, its constitution is more like a Peruvian plant than one of Ceylon or Java. Of late years a wild tuberose, Polyanthes gracilis, has been found in South Brazil, which is probably the origin of the garden plant.

The tuberose is too tender a plant to be cultivated in England in the open air; but in the south of Europe it finds a climate suitable to it; and the Genoese supply the principal part of the European market with tubers for forcing. The latter are imported into this country by the Italian oilmen, who sell them, with orange-trees, Narcissus roots, and similar products of the south.

---

* Only two years ago a friend of ours saw large quantities of corn abandoned, because the prices in the ports of the Baltic would not repay the expense of conveyance.

In selecting tuberoses for planting, the largest tubers should be preferred, as the smaller ones will often not flower. All offsets should be carefully picked off, so as to concentrate the vegetation in a single eye. They should be planted in March, in pots, in rich light soil, and forced in a hotbed, with as much bottom heat as is given to a melon. The eye should be about an inch below the surface of the soil. Very little water should be given till the plants are growing; but when once in a state of vigour, they may be supplied copiously. An abundance of light and air should be given the plants as soon as they begin to grow, and this should be sedulously attended to as long as they remain in the hotbed; it will however soon be necessary, on account of their height, to remove them to the greenhouse, where they must be placed near the glass, and their roots still exposed to a temperature similar to that from which they were taken. As soon as they show their flowers, but not sooner, they may be removed to the sitting-room, when their flowering will be completed.

POLYANTHUS, a garden variety of the oxlip primrose, with brown flowers, is one of those plants which have from time immemorial been favourites in gardens. It was probably obtained by accident, and is now propagated either by seeds or division of its root. Florists require that a good variety of this flower should possess a strong scape, a well-filled truss, a corolla with a short tube, a bright yellow eye, and a deep rich brown crimson limb, bordered with a well-defined yellow edging. They require less careful cultivation than the auricula [AURICULA], and principally need shade and rich soil. Their beauty however diminishes with their age, so that a renewal of the variety from seed is requisite every few years.

POLYANTHUS NARCISSUS is the same as Narcissus Tazzetta. [NARCISSUS.]

POLY'BIUS, the son of Lycortas, was born at Megalopolis in Arcadia. The exact year of his birth is not stated by any good authority, and the account of Suidas, who places it in the reign of Ptolemæus Euergetes (who died about 222 B.C.), is irreconcilable with what Polybius himself (xxv. 7) relates, that in the reign of Ptolemæus Epiphanes, when he was to have accompanied his father on an embassy to that king, he had not attained the legal age, which, according to Polybius himself, was thirty, previous to which the law did not allow any one to take part in public affairs. • According to the statement of Suidas however, Polybius at this time would have been about 40 years old. Now the year in which the Achæans intended to send him with his father to Egypt was 180 B.C.; and as at that time he had not attained his thirtieth year, we shall not be much mistaken in supposing, with Casaubon, that he was born about 204 B.C., so that at the time of the intended embassy he must have been about 25 years of age. He seems to have acquired the principles of political and military science at an early age; for his father was a distinguished general, and one of the heads of the Achæans, and it is expressly mentioned that he enjoyed the practical training of Philopœmen, the greatest general of the Achæans. When Philopœmen died, Polybius is said to have been one of those who carried the urn containing the ashes of the deceased to the grave. (Plut., *Philop.*, c. 21.) During the war of the Romans against Perseus, king of Macedonia, he advised his countrymen to observe a strict neutrality; but when they determined to lend their assistance to the Romans, he was entrusted with the command of the cavalry (169 B.C.), and was sent as ambassador to the consul Q. Marcius, to declare that the Achæans were ready to give their assistance as soon as might be required. (Polyb., xxviii. 3, 6.) The year following, when the two Ptolemæi, kings of Egypt, asked the Achæans for support against Antiochus, it was particularly stipulated that Polybius should be appointed commander of the horse, which shows that he had already distinguished himself in a military capacity. After the destruction of the kingdom of Macedonia, the Romans, not satisfied with having taken cruel vengeance on those Achæan states, which they suspected of having secretly supported the cause of Perseus, made out a list of 1000 distinguished Achæans, and sent them to Italy to be tried. But instead of being brought to trial, they were distributed among the towns of Italy. Polybius, who was one of the number, was more fortunate than his fellow-prisoners, for his genius and talents attracted the attention of Æmilius Paulus, who made him the instructor of his two sons Fabius and Scipio. Those young men, who became greatly attached to him, requested and obtained permission for Polybius to remain at Rome. Polybius himself (xxxii. 9, 10) relates a charming anecdote of the tenderness which Scipio, the younger of the two brothers, showed to him; and he adds that Scipio never left him afterwards, but preferred his company and conversation to everything else. During his long stay at Rome, Polybius on several occasions exerted his influence in favour of his countrymen, and at length, in 150 B.C., he succeeded, with the co-operation of Scipio, in obtaining for the Greek prisoners permission to return home; but during the period of 17 years which had elapsed since their arrival in Italy, their number had been reduced to 300. Polybius seems to have accompanied them on their return, in order to admonish his countrymen not to divide their strength, and to recognise the superiority of the Romans, whose power it would be hopeless to resist; for an inscription mentioned by Pausanias (viii. 37) recorded the regret of the Achæans at not having followed his wise advice, by which they would have escaped the catastrophe of their final political annihilation. Polybius soon returned to Rome, to accompany his friend Scipio on his military expeditions. It must have been before this time that he had conceived the idea of writing his great historical work; and for this purpose he made more profound and extensive studies than any other antient historian. He not only studied the Roman constitution, and searched the archives which were thrown open to him through his connection with the most distinguished Romans, but he undertook long journeys across the Alps into Gaul, Spain, and to the coasts of the Atlantic. It is not certain whether he made these journeys previous to the year 150 B.C., or after his return from Greece, though it seems probable that he may have availed himself of the opportunity of visiting Spain when Scipio went to that country as military tribune in 151 B.C. Five years later, when Scipio besieged and destroyed Carthage, he was again accompanied by Polybius, who seems to have taken an active part in the Roman army, for in an inscription quoted by Pausanias (viii. 30), he is called the ally of the Romans. Pliny says that during the siege of Carthage, Polybius explored the north coast of Africa, in which undertaking, as on his former journeys, he was provided with everything that could facilitate the accomplishment of his objects. Immediately after the destruction of Carthage (146 B.C.) he hastened to the Peloponnesus, where, in the mean time, a war with the Romans had broken out. But he arrived too late: Corinth had already fallen, and all he could do for his unhappy country was to endeavour to obtain from the conquerors the mildest possible conditions, and to rescue from their hands the statues of Philopœmen and Aratus, with whose memory the happiest associations of his countrymen were connected. After the Roman commissioners had left Greece, in 145 B.C., he was appointed by them to regulate the affairs of the different states. With the most indefatigable zeal he traversed the country, everywhere endeavouring to restore peace and unity, and to introduce salutary regulations. His merit on this, as well as former occasions, was duly acknowledged and rewarded throughout Peloponnesus, and statues, with inscriptions recording his exertions on behalf of his country, were erected at Megalopolis, Acacesium, Mantinea, Pallantium, Tegea, and other places. Soon after he had settled the affairs of his country, he made a voyage to Egypt, which, according to Strabo, he visited in the reign of Ptolemæus Physcon, who ascended the throne in the same year that Corinth was destroyed. The remaining years of his life he seems to have applied to the revision and completion of his historical works, unless we suppose, with Schweighaeuser and others, that in the year 134 B.C. he again accompanied Scipio on his expedition against Numantia, for which however we have no direct authority. Cicero (*Ad. Famil.*, v. 12) merely mentions a work of Polybius on the war against Numantia. The time of his death is uncertain, for the only information that has come down to us is the statement of Lucian (Macrob., c. 23), who says that Polybius, on returning from the country, fell from his horse, and shortly after died from the fall, at the age of 82. Supposing this statement to be correct, he must have died about the year 122 B.C.

The great historical work of Polybius (ἡ τῶν καϑόλου πραγμάτων σύνταξις), in 40 books, consisted of two distinct parts, the first of which comprised a period of 53 years from the beginning of the second Punic war to the overthrow of the kingdom of Macedonia, including the immediate consequences of this event, that is, the pacification of Rhodes, and the sending of the 1000 Achæan prisoners to Italy. The second part began with the war in Spain against the Celtiberians and Vaccæans, and ended with the destruction of Corinth. It is evident, from various circumstances (Niebuhr, *Hist. of Rome*, vol. iii., p. 49), and especially from the manner in which Polybius (iii. 1-5) speaks of these two divisions of his work, that they were written and published at different times, and afterwards put together to form one whole. The latter part was written after the fall of Corinth, and the former some years before that event. The first two books are an introduction to the first division of the work, and contain a sketch of the History of Rome, from the taking of the city by the Gauls to the beginning of the second Punic war. The second division of the work, the principal object of which was to describe the fate of Carthage and Greece, and the causes which led to it, was likewise preceded by a kind of introduction, consisting of a brief history of the interval between the overthrow of the Macedonian kingdom and the events which led to the fall of Carthage and Corinth. The great object of the history of Polybius was to show how the Romans, with their admirable constitution and their unity of purpose, within a short period gained the dominion over the greater part of the known world. Thus, although the history of Rome formed, as it were, the nucleus of his work, it was still essentially a universal history; and every nation, with its history and institutions, as it came in contact with the Romans, was treated with equal attention. To enable the reader to form a clear estimate of the contents of the whole work, we shall give an extract from the plan which Polybius himself laid down for it. After giving an explanation of the causes of the second Punic war, Polybius describes the invasion of Italy by the Carthaginians, and how they brought the Roman republic to the brink of destruction. The accuracy of his description of the passage of Hannibal over the Alps has been demonstrated, step by step, by General Melville. He then proceeds to show how Philip, king of Macedonia, after the end of his war against the Ætolians, entered into an alliance with the Carthaginians. 'I shall next,' says he, 'give an account of the disputes between Antiochus and Ptolemæus Philopator, about Cœle-Syria, and the war which arose out of them; of the manner in which the Rhodians, and Prusias, king of Bithynia, compelled the Byzantines to cease levying the passage-money which they had been accustomed to demand of those who sailed into the Euxine. Here we shall break off our narrative, and turn our attention to the Roman republic, and show that it was to its constitution that it owed its greatness and its dominion over the world. At the same time, we shall make some digression to show how Hiero of Syracuse lost his independence; next to which I shall describe the disturbances of Egypt, and how, after the death of Ptolemæus, Antiochus and Philip formed an alliance, with a view of dividing the kingdom of Egypt between them; how at first they acted insidiously, until at length Philip made open war on Egypt and Samos, while Antiochus invaded Cœle-Syria and Phœnicia. After this, I propose to give a brief account of what took place between the Romans and Carthaginians, in Spain, Africa, and Sicily. This will lead me to Greece, and after having related the maritime war of Attalus and the Rhodians, as well as that of the Romans against Philip, I shall describe the immediate consequences of these events; the exasperation of the Ætolians, by which they were induced to call Antiochus to their assistance, which occasioned the war between the Asiatics and the Achæans and Romans. After having explained the causes of this war, and the passage of Antiochus into Europe, I shall describe, first, his flight from Europe; secondly, how he was conquered by the Romans, and compelled to give up all Asia west of Mount Taurus; and thirdly, in what manner the Romans, after the chastisement of the Galatians, gained the undisputed sovereignty of Asia. After this shall follow an account of the calamities of the Ætolians and Cephallenians; of the wars of Eumenes against Prusias and the Gallogræcians, and of that which they carried on with Ariarathes against Pharnaces. Then, after having described the union and the arrangements of the Peloponnesians, and the prosperity of the republic of the Rhodians, I shall subjoin a short recapitulation of my whole narrative. Finally, I shall add an account of the expedition of Antiochus Epiphanes into Egypt, of the war against Perseus, and the overthrow of the kingdom of Macedonia. From the history of these events,' says the historian, 'it will be manifest how the Romans made themselves masters of the whole world.' The second division of the history of Polybius began with the war of the Romans against the Celtiberians and Vaccæans in Spain, and proceeded to describe those of the Carthaginians against Massinissa; of Attalus against Prusias; and how Ariarathes, king of Cappadocia, after being driven out of his kingdom by Orophernes, again gained possession of it; and how Seleucus, king of Syria, lost his life and his kingdom. Then followed the history of the affairs between Carthage and Rome, which ended in the destruction of the former. The whole work concluded with the history of the rebellion of the Macedonians against the Romans, and the separation of the Lacedæmonians from the Achæan league, which led to the great catastrophe by which Greece was made a Roman province. These were the chief heads; but the work was interspersed with episodes or dissertations on various subjects, such as tactics (vi. 17-40), geography (xxxiv.), political institutions, &c., which the author thought necessary to insert, partly to render his narrative more intelligible, partly to refute false opinions current among his countrymen. Whatever we may think of these episodes, looking at the whole work in an artistical point of view, we are indebted to them for the soundest information on many subjects connected with the history of antiquity, especially that of Rome; and it is only to be regretted that many points in his dissertation on Roman tactics are not quite so clear to us as we could wish.

The study and research of Polybius before he began to write his work, together with his almost unparalleled impartiality and love of truth, have given it a character of authenticity such as very few historical works, either of antient or modern times, can claim. He is a severe critic of his predecessors, with whose writings he was thoroughly acquainted; and although he himself was under the greatest obligations to the Romans for their behaviour to him, still he did not spare them wherever they deserved censure (see especially ix. 10, and xviii. 18). The love of his country moreover did not make him blind to the folly of its leaders, who endeavoured to draw it into the fatal conflict with Rome. But the distinguishing character of his work is its didactic and practical tendency (*ἱστορία πραγματική*). He did not write for the sake of amusement, or of filling the memory of his reader with a number of unconnected facts, but he traces events back to their causes, and deduces from them the most useful precepts, much in the same way as the so-called 'histoires raisonnées' of modern times, but with infinitely more wisdom and discretion. It is true that he thus wishes to guide his reader, and not to allow him to form his own opinions; but setting aside the consideration that an intelligent reader may and will always judge for himself, who would not willingly listen to the arguments and reasonings of a statesman and a general like Polybius? His work is full of the most profound political and military wisdom; or, as a modern historian expresses it, 'a code of the wisest political and military maxims;' and enables the reader not only to understand the past, but to look upon the future with the foreseeing eye of a prophet. As the object of Polybius was not to make his work popular with the multitude, but to instruct and guide men who are entrusted with the care of their country, he abstained from all rhetorical embellishments of style. He looked with contempt upon the refined affectation and hollowness of the rhetoricians of his time, for true public oratory had long ceased among the Greeks. Hence he very seldom introduced his heroes making speeches, though it still was and remained a favourite custom with his countrymen down to the latest period of their literature; but where he thinks it necessary, he gives the substance of their speeches in his own words. It is natural that under these circumstances the rhetoricians of his own as well as of a later age should have been unable to appreciate Polybius. (Niebuhr, *Hist. of Rome*, vol. i., p. 533.) Dionysius, though in many respects a judicious critic (*De Comp. Verb.*, c. 4), says that the history of Polybius is written in such a style that no one can endure to read it through from beginning to end. Polybius has also been censured for having introduced into his work a number of foreign words and expressions; but the specimens that have hitherto been collected are few, and some of them are doubtful. We may however admit that there were more of such expressions in those parts of his work which are no longer extant; but his long absence from his country, and an intense study of the institutions and literature of another nation, sufficiently account for this. Another charge which has been brought against Polybius in modern times is that of a want of sympathy with the sufferings of his own country. That this want is merely apparent, and perhaps owing to his philosophical mode of viewing things, is sufficiently evident from his whole conduct towards his country; and the fragments of his work lately discovered by A. Mai, in which he describes the sufferings of his countrymen, are full of expressions of the deepest sorrow for their calamities.

It may be chiefly owing to his style that the works of Polybius in subsequent ages were less read and copied than others of a greatly inferior character, and that to this cause we have to ascribe the loss of the greater part of them; for of the forty books, only the first five are preserved entire; and of the rest, we possess only fragments and extracts. At the time of the revival of letters, about the middle of the fifteenth century, and long before any part of the Greek text was printed, an elegant but incorrect Latin translation of the first five books was published by Nicolaus Perotti at Rome. In 1529 the Greek text, with a Latin translation of the dissertation 'De Militia Romana,' by Lascaris, appeared at Venice; and it was a year later that the Greek text and the Latin translation of the first five books by Perotti were edited by Orsopoeus. As soon as the merits of Polybius began to be acknowledged, and a desire was awakened to possess more of his work, the number of new fragments continued to increase. In 1536 eight chapters of the sixteenth book were discovered and published; and in 1549, extracts from books vii.-xvii., together with a fragment of the 19th chapter of book i., which had hitherto been wanting, were added from a MS. which had been brought over from the island of Corfu. A very important addition to the fragments of Polybius was made in 1582 by Fulvius Ursinus, who, for the first time, published the first section of the 'Excerpta,' from various antient historians, which, in the tenth century, the emperor Constantinus Porphyrogennetus had ordered to be made, and which contained a great many extracts from the history of Polybius. This section contained the 'Excerpta de Legationibus' ('Εκλογαὶ περὶ πρεσβειῶν). Casaubon, in 1609, published a complete edition of all that had till then been discovered of the works of Polybius, and made a new Latin translation of the whole. The second section of the Excerpta of Constantinus, called 'Excerpta de Virtutibus et Vitiis' (περὶ ἀρετῆς καὶ κακίας), which likewise contained a considerable number of extracts from Polybius, together with some other new fragments, were edited and translated into Latin by Henry Valesius (Valois), at Paris, in 1634. Nothing new was added but a fragment containing an account of the siege of Ambracia, by J. Gronovius, until, about fifteen years ago, when A. Mai discovered, in the Vatican library, a palimpsest of the third section of the Excerpta of Constantinus, called 'Excerpta de Sententiis' (περὶ γνωμῶν, which, among other extracts, contained a considerable number belonging to Polybius. The MS. however was in such a mutilated state, that a great part of the extracts as published by Mai are scarcely intelligible. A somewhat better edition of these Excerpta, with a Latin translation and commentary, was published at Leyden, in 1829, by J. Geel. The best edition of Polybius, containing all that was known at the time, is that of Schweighaeuser, in 8 vols., Leipzig, 1789-95: a reprint of it appeared at Oxford in 1823, in 5 vols. Among the translations of Polybius we may mention the German, by Seybold, in 4 vols., Lemgo, 1779-83; and the English, by Hampton, in 2 vols. 4to., 1772. There are also the following English translations:—'The Hystories of the most famous and worthy chronographer Polybius: Englished by Charles Watson,' 1568; 'Polybius,' translated into English by Edward Grimestone, 1634; 'Polybius,' translated by Sir Henry Sheares, with a character of Polybius and his writings by Dryden, 3 vols., London, 1698.

The greater part of the history of Polybius is thus lost. After Livy had almost reached the end of the second Punic war, he began to make use of Polybius; and he very often gave a literal translation of the Greek original: thus he has perhaps preserved more than we are aware of, as he seldom mentions his authorities. Much may also be preserved in Cicero's work 'De Republica,' as Cicero, in his historical statements, chiefly followed the authority of Polybius.

Polybius, as mentioned above, is said by Cicero to have written a separate work on the war against Numantia, but nothing is known of it. His memoirs of the life of Philopœmen (x. 24) are also lost. It is however not improbable that in the accounts which Plutarch and Pausanias give of Philopœmen, we may still possess the substance of those memoirs. Other works of Polybius mentioned by some of the antients, on tactics and subjects of geography, were probably not separate works, but dissertations which formed parts of his History.

POLY'BIUS. (Zoology.) [PORTUNIDÆ.]

POLY'BORUS. [FALCONIDÆ, vol. x., p. 168.]

POLYBRANCHIATA, M. de Blainville's name for his second order of *Paracephalophora Monoica*, consisting of the families *Tetracerata* and *Dicerata*. The first of these families consists of the genera *Glaucus*, *Laniogerus*, *Tergipes*, *Cavolina*, and *Eolidia*; the second, of the genera *Scyllæa*, *Tritonia*, and *Tethys*. [EOLIDIA; GLAUCUS; NUDIBRANCHIATA.] N.B. *Cavolina* is erroneously referred to *Psilosomata*, instead of the title which heads this article.

PO'LYBUS, or POLY'BIUS (Πόλυβος, or Πολύβιος), a pupil and son-in-law of Hippocrates, who lived about the middle of the fifth century B.C., in the island of Cos. He assisted Thessalus and Draco, the sons of Hippocrates, in establishing the antient school of the Dogmatici, which was also sometimes called the Hippocratic sect, from its professing to follow the principles that he laid down. Galen praises him, and says that he never abandoned the opinions and mode of practice of his father-in-law (*Comment. in Hippocr.*, lib. i.; *De Nat. Hom.*, p. 11, 12, ed. Kühn); but, as Eloy remarks (*Dict. Hist. de la Méd.*), if the works attributed to him are really his, it must be confessed that he does in some instances differ from Hippocrates, particularly respecting the passage of liquids into the trachea and the lungs. The following treatises, which are generally printed among the works of Hippocrates, are supposed to have been written by Polybus:—1, περὶ γονῆς, 'De Semine;' 2, περὶ φύσιος παιδιόν, 'De Naturâ Pueri;' 3, περὶ διαίτης ὑγιεινῆς, 'De Salubri Victûs Ratione;' 4, περὶ παθῶν, 'De Affectionibus;' and 5, περὶ τῶν ἐντὸς παθῶν, 'De Internis Affectionibus.' (Choulant, *Handbuch der Bücherkunde für die Aeltere Medicin, &c.*, Leipzig, 1828, 8vo.) Many persons also attribute to him the treatise περὶ φύσιος ἀνθρώπου, 'De Naturâ Hominis,' which is found among the works of Hippocrates; but, according to Galen (*loco cit.*), incorrectly. He is several times mentioned by Galen (*Opera*, ed. Kühn, tom. vii., p. 960; tom. xv., p. 11, 175; tom. xvi., p. 3): his name occurs also in Celsus (*De Med.*, p. 243, 265, 338, ed. Argent.); Cælius Aurelianus (*De Morb. Acut.*, lib. iii., cap. 9); Pliny (*Hist. Nat.*, lib. xxxi., cap. ult. in fine); and Thessalus (in *Orat. ad Athen. inter Opera Hippocr.*, tom. iii., p. 843, ed. Kühn). A Latin translation of the work 'De Salubri Victûs Ratione' was published by J. Placotomus (*Bretschneider*), Antwerp, 1561, 12mo., and it is inserted in several editions of the 'Regimen Sanitatis Salernitanum.' The whole of his 'Opuscula' were published in a Latin translation, Basil., 1544, 4to., per J. Oporinum; and there is an Italian translation by Pietro Lauro, Venez., 1545, 4to.

POLYCARPUS, one of the fathers of the Christian church, and one of a small number who were distinguished from the rest by the term Apostolic Fathers, as having been contemporaries of some of the Apostles. The period of his death is well ascertained to have been in A.D. 167, in the reign of Marcus Aurelius; the period of his birth is placed perhaps somewhat too early when it is referred to the reign of Nero. However there seems no reason to doubt that he was contemporary with Saint John, and known to him, the lengthened period of whose life connects so fortunately the men of the second century with those who had been in personal attendance on our Saviour.

It is this circumstance which gives its chief importance to the lives of these persons, and thence arises the main value of the few and in other respects unimportant writings which remain of the Apostolic Fathers. The lives form links in the chain of Christian tradition; and the writings recognise by frequent quotations the writings which remain of the evangelists and apostles.

Of the writings of Polycarp only one small epistle remains. It is addressed to the Philippian church, exhorting them to the practice of their Christian duties and the maintenance of the purity of the faith. But there is another writing of that age of which he is the subject. It a relation of the manner of his death, written by the church at Smyrna, of which he was the bishop, addressed to the church of

Philadelphia. It is a valuable and interesting memorial. There seems to have been a mad and wicked attempt to extirpate Christianity in Asia Minor. The persecution raged with peculiar violence at Smyrna. Many Christians were delivered to the lions. Polycarp, the bishop, was reserved for a more cruel death, being burned at the stake. Both these epistles may be read in an English translation in a volume published by archbishop Wake containing all the genuine remains of the Apostolic Fathers.

What further is known of him is, that when the controversy began between the Eastern and Western churches respecting the proper time for the observance of Easter—a childish matter of disputation, which however produced much ill feeling for many centuries in the Christian church—Polycarp was sent to Rome to discuss the question with Anicetus, the bishop, and other Christians there; and that while at Rome he strenuously opposed the heresies of Marcion and Valentinus. This fact is stated by Irenæus, bishop of Lyon, who was a pupil of Polycarp.

POLY'CERA. [CYCLOBRANCHIATA, vol. viii., p. 249.]

POLYCHROITE, the colouring matter of saffron [SAFFRON], which consists of the dried stigmas of the flower of the *Crocus sativus*. This substance was first examined in 1811, by Bouillon Lagrange and Vogel, who gave it the name which it bears, on account of the variety of colours which it is susceptible of exhibiting. It is procured by infusing saffron in water, evaporating the solution to the consistence of honey, digesting the residue in alcohol, and evaporating the solution to dryness.

The properties of polychroite are, that it has a very deep yellow colour; by exposure to the air it absorbs moisture, and becomes viscid. Water and alcohol dissolve it readily, but æther and oils do not; the sun's rays destroy the colour of the aqueous solution of polychroite, and it cannot be restored. Sulphuric acid renders both the aqueous and alcoholic solution of polychroite of a deep indigo-blue colour, which gradually changes to lilac; nitric acid gives them a green colour, which disappears on the addition of water; chlorine destroys the colour entirely. Lime-water precipitates a solution of polychroite, yellow; barytes-water, red; sulphate of iron, dark-brown; diacetate of lead, saffron-coloured; nitrate of mercury, red: acetate of lead produces no change in it.

When strongly heated, polychroite is decomposed, and there are produced water containing an acid, a yellow-coloured oil and a darker one, carbonic acid, and carburetted hydrogen; the charcoal remaining yields cyanogen when calcined with potash. Polychroite does not appear to have been analyzed.

POLYCHRO'MY, a modern term (from the Greek πολὺς and χρῶμα) used to express the antient practice of colouring statues and the exteriors of buildings. It is difficult to define exactly what the system of colouring was, but it appears from the remains of colour found upon antient monuments, that at the zenith of Grecian refinement, both in the polychrome sculpture and architecture, the colouring was strictly confined to the ornamental parts; since no traces of colour have ever been found upon the naked in sculpture, or upon the walls of temples when of marble.

There is scarcely any notice of the system or practice of colouring architecture in any of the antient writers. A few remarks occur in Vitruvius and Pausanias, which may be construed into an allusion to it, but they are vague, and the systems which have been laid down by several modern writers rest chiefly upon conjecture. It is more than probable, where the architectural members were subject to so great a variety of forms and proportions, that the decorations in colour, which admit of endless variety, were quite arbitrary, and the limits of the system consisted only in the architectural members to which their application was restricted. Remains of colour have been found by travellers upon ornamental work in most of the architectural ruins of Greece. Many traces were discovered by Dodwell, Stuart, Chandler, Bröndsted, Semper, and others, upon the principal Athenian monuments: upon the temple of Theseus, the Parthenon, the Propylæa, the Erechtheium, the temple on the Ilissus, the monument of Lysicrates, the outer propylæa of the temple of Ceres at Eleusis, and the greater temple at Rhamnus; also upon the temple of Apollo at Bassæ in Arcadia, the Doric ruins at Corinth, and the temple of Minerva in Ægina; upon the temples of Selinus in Sicily, and upon the basilica at Pæstum.

Upon all these temples, except the Doric ruins at Corinth, and the temple of Minerva in Ægina (commonly called the temple of Zeus Panhellenius), which were not of marble, the colouring was confined to the mouldings and other ornaments, the friezes, the metopes, and the tympana of the pediments. The exterior of the wall of the cella of the temple of Ægina and the columns of the Corinthian temple were covered with a stucco and coloured red. In a ruder age, when most temples were constructed of wood, before the use of marble or other stone, the application of colours was undoubtedly more general and much less systematic, not only among the Greeks, but with most of the nations of antiquity. In Egypt it was at all times a universal custom to have recourse to colours in the decoration of architecture. In later times amongst the Romans, in the times of Vitruvius and Pliny, the practice seems to have degenerated into a mere taste for gaudy colours, and to have been very general, as we see in the ruins of Pompeii, where however occasionally the Arabesque decorations upon the walls of the courts in the larger houses are very elegant.

With regard to the system of decorating the mouldings, it appears, from the traces found upon antient monuments, that they were painted in various ways and in a great variety of colours, whether carved or plain; and a tasteful combination of colours must have greatly heightened the effect of even the richest mouldings. These decorations were not confined to the mouldings of the entablature; the ovolo, echinus, and abacus of the capital, and the toruses of the base, were also sometimes coloured. Foliage, ova, and beads were the ordinary decorations, but on the Doric tænia a fret was generally painted; and the cymatia of the pediment-cornices were frequently ornamented with gilded metal-work; the acroteria were also surmounted with gilded figures. Upon the larger mouldings, on which foliage was painted, the outlines of the leaves were engraved in the stone. The mutules, dentils, modillions, and the soffits were also variously coloured, but the Doric guttæ were apparently generally gilded. The faciæ of the architraves and the coronæ of the cornices were left plain, but the Doric architrave was sometimes ornamented with gilded shields, as in the Parthenon at Athens, which were placed immediately beneath the metopes. It appears that all friezes which were decorated with sculpture were coloured, which was absolutely necessary to give the sculpture a proper relief; for the same reason the tympana of the pediments would also require colour. In the Doric order the tympanum would necessarily be of the same colour as the metopes: in the Parthenon they were of a pale blue; and in some of the Sicilian monuments red has been found. The metopes require colour, with or without sculpture, to throw the weight of the pediment upon the triglyphs, its natural supporters, which being left plain, united the cornice with the architrave, and gave the whole building an elegant lightness of effect which it otherwise could not have.

Polychrome sculpture was quite as general amongst the Greeks as polychrome architecture; it is frequently alluded to by almost all the antient writers, and many statues of this kind are minutely described by Pausanias. The acrolithic and the chryselephantine statues both come under this head. In the latter style were many of the most remarkable productions of antient art—the Jupiter at Olympia, and the Minerva at Athens, by Phidias; the Juno at Argos, by Polycletus, and the Æsculapius at Epidaurus, by Thrasymedes; and others described by Pausanias. In the flourishing period of Grecian art, custom seems also to have defined limits to this practice, for except in the rudest ages, the naked itself was never painted, although it appears to have been sometimes covered with an encaustic varnish. That the naked marble of the works of the greatest sculptors was not coloured, we have most conclusive proofs from Lucian, in the dialogue between Lycinus and Polystratus. (*De Imag.*, 5-10.) The colouring was confined to the lips, the eyes, the hair, the drapery, and the ornaments of the dress; the hair was often gilded, as in the case of the Venus de' Medici, and in many statues glass eyes were inserted with eyelashes of copper, examples of which are still extant.

Alluding to this practice, Flaxman remarks, 'It seems to have been common to most countries, particularly in the early and barbarous states of society. But whether we look on the idols of the South Seas, the Etruscan painted sculpture and terra-cotta monuments, or the recumbent coloured statues on tombs of the middle ages, we shall generally find the practice has been employed to enforce superstition, or preserve an exact similitude of the deceased. These however are in themselves perverted purposes; the real ends of painting, sculpture, and all the other arts, are to elevate the mind to the contemplation of truth, to give the judgment a rational determination, and to represent such of our fellowmen as have been benefactors to society, not in the deplorable and fallen state of a lifeless and mouldering corpse, but in the full vigour of their faculties when living.'

For further information on this subject the following works may be consulted:—Kugler, *Ueber die Polychromie der griechischen Architectur und Sculptur und ihre Grenzen;* Semper, *Vorläufige Bemerkungen über bemalte Architectur und Plastik bei den Alten;* Quatremère de Quincy, *Le Jupiter Olympien;* and Stuart's *Antiquities of Athens.*)

PO'LYCHRUS, Cuvier's name for a genus of Saurians. [PLEURODONTS.]

PO'LYCLES. There were two sculptors or statuaries of Greece so called. They are noticed by Pliny and Pausanias, but in so undefined a manner that it is not always easy to distinguish which of the two artists is referred to. The first Polycles lived in the hundred and second Olympiad, or about 370 B.C., and was therefore contemporary with some of the greatest sculptors of antiquity, as Cephissodotus, Praxiteles, Leochares, and Lysippus. The second was flourishing in the hundred and fifty-fifth Olympiad, or about 170 years before our æra. He was the son of Timarchides, a statuary of Athens; but his master's name was Stadieus. (Paus., lib. vi., c. 4.)

The works of this Polycles and of his brother Dionysius were carried to Rome with other fine monuments of Greek art. Pliny (*Hist. Nat.*, xxxvi. 5) mentions that a statue of Juno, the joint production of these two sculptors, was placed in the temple of that goddess within the portico of Octavia; and near it was a statue of Jupiter, also the work of the two sons of Timarchides. Polycles has been supposed, from a passage in Pliny, to be the author of the original statue of the Hermaphrodite from which the well known existing representations—especially that usually called the Borghese Hermaphrodite, from its having belonged to that collection, though it is now in the Louvre—are copies. Pliny (xxxiv. 8) says, *Polycles hermaphroditem nobilem fecit.* This Polycles, the pupil or scholar of Stadieus, according to Pausanias (lib. vi., 4), made a statue of Amyntas, a pancratiast, or conqueror in the games, which was preserved at Olympia. Some statues of the Muses were also executed by Polycles. Polycles left sons who followed their father's profession.

POLYCLE'TUS, one of the most celebrated statuaries of antient Greece.

This name has given rise to much discussion from the difficulty that exists in determining how many artists were so called, and what works each produced. Pausanias (lib. vi., 6), speaking of a statue of a youth, says it was the work of Polycletus the Argive; but, he adds, 'not he who made the statue of Juno.' From this it seems clear that there were at least two Polycleti, and that both were natives of or connected with Argos; it may also be assumed that they were living nearly at the same time. Pliny (*Hist. Nat.*, xxxiv. 8) alludes to a Polycletus Sicyonius, attributing to *him* the works which gained for their author the reputation of one of the greatest artists of antiquity. The above, added to the statement of Pausanias, leads to the conclusion either that there were three sculptors of the name, two Argives and one a Sicyonian, or, as is most probably the case, that there were but two, and that the Sicyonian, the more celebrated, was also called *Argivus*. The most important of his works, and more especially his 'Juno,' were at Argos, and it has been reasonably surmised that he may have been so far honoured by that people as to have the citizenship of Argos conferred upon him.

Polycletus the Sicyonian was the scholar of Ageladas of Argos; and lived about the eighty-fourth Olympiad—an epoch illustrated by the talents of Ageladas, Myron, Phidias, Alcamenes, and the brightest names in the annals of art. There is an extensive list of the various admirable productions of Polycletus. Some of these are unquestionably to be attributed to the so-called Sicyonian; some may be of the second Polycletus, but, for the reasons before stated, it is not easy to appropriate them with any certainty. Among the chief works of Polycletus may be mentioned the colossal statue of Juno which decorated the temple of that goddess at Argos, and which was considered in many respects to equal the finest productions of his contemporary and rival Phidias. It was chryselephantine, or composed of gold and ivory: all the naked parts being of ivory, while the precious metal was employed for the drapery and accessories. The dimensions of this statue were less than those of the Olympian Jupiter which Phidias executed for the people of Elis, and of the Minerva of the Parthenon. The goddess was represented seated on her throne. In one hand she held a sceptre; in the other a pomegranate. The accompaniments and ornaments, having reference to mythological subjects, were of the richest description and most elaborate workmanship. This, taking it altogether, was considered the greatest work of Polycletus, but he was hardly less celebrated for others of a less ambitious character. Amongst these were two statues of young men, one, called 'Diadumenos,' fastening a band round his head, which was treated in a soft or delicate manner, 'molliter;' the other, 'Doryphorus,' of a more manly character, 'viriliter,' carrying a lance. A group of two naked boys called 'Astragalizontes,' playing at a game called Tali (with bones), is also celebrated; also some statues of Canephoræ (female figures carrying baskets on their heads), an Amazon, as well as several statues of Athletes (conquerors in the public games), and others. The Canephoræ were so much admired, that Cicero declares (*in Verr.*, iv.) that strangers at Messene crowded to see them, 'and the house in which they were preserved was less its master's than the ornament or attraction of the whole city.' The estimation in which another of his works, the *Diadumenos*, was held, may be conceived from the statement of Pliny, that it was 'centum talentis nobilitatum,' valued at one hundred talents. But of all the productions of this great master none has a greater claim to notice than that which, for its excellence, was called the *Canon*, or rule of art. This was a statue so perfect in its proportions that artists referred to it, and were bound by it as by a kind of law. 'Lineamenta artis,' says Pliny (xxxiv. 8), 'ex eo petentes, velut à lege quâdam.' Some have supposed that this figure was the Doryphorus; and the reason for this belief—and it is not without its force—is derived from a story recorded of the celebrated Lysippus, who, being asked from what master he had learned his art, replied, 'the Doryphorus of Polycletus.' On the other hand, the manner in which Pliny expresses himself respecting the 'Canon,' would warrant the assumption that it may have been some work distinct from the Doryphorus: In some copies we read 'idem et Doryphorum viriliter puerum fecit, et quem Canona artifices vocant;' another edition gives the passage thus: 'Diadumenum fecit molliter juvenem . . . . ; idem et Doryphorum viriliter puerum. Fecit et quem Canona,' &c.; showing at least that a difference of opinion has existed on the subject. It may fairly be questioned how far any single or particular work can properly be a *canon of art*—a rule by which works of different qualities and characters can be successfully executed; and it seems much more probable that the canon of Polycletus, whether or not it was the Doryphorus, was only a standard of excellence for works of its own particular character. We think this is the interpretation that must be given to it by all practical artists.

It is the highest praise to Polycletus to say he was a worthy competitor and rival of Phidias. On one occasion, when five of the most eminent artists of the day, Phidias being of the number, executed five statues in competition, that of Polycletus was preferred. It is also said that he carried to perfection the *Toreutic art* which Phidias had, as it were, commenced. Polycletus is declared by Pliny to have succeeded *only* (or perhaps it should be read *best*) in statues of a soft or gentle character. He also says that he first made figures resting on one leg. On the authority of Varro he also acquaints us that he preserved a certain squareness in some of his works, and that they were all made according to one model or *exemplar*. With respect to the former part of this charge, that of squareness (*quadrata*), it is likely that the style which characterised art immediately before what has been termed the Phidian period, may still have been partially continued, and, as Polycletus was one of the scholars of the hard and dry school, it is natural that some of his works may have shown evidence of the age of Ageladas; but that he had much improved upon the character of the earlier art, is proved by the opinion which Cicero has recorded of the state of style about the æra of Polycletus: 'Quis non intelligit Canachi signa rigidiora esse quam ut imitentur veritatem? Calamidis dura illa quidem, sed tamen molliora quam Canachi;

nondum Myronis satis ad veritatem adducta . . . . . . Pulchriora tamen Polycleti et jam planè perfecta,' &c. (Cic., *De Clar. Orat*, c. 18.) It may be observed here that Myron and Polycletus were always considered rivals. Pliny says, 'æmulatio etiam in materiâ fuit;' for one used the bronze of Ægina and the other always employed that of Delos for their works. The judgment of antiquity has given to Polycletus the reputation of one of the most remarkable artists of his extraordinary age. Our notice of him has necessarily been much compressed, but a fair estimate of the honour in which he was held as a great master of his art may be made not only from the recorded opinions of writers, but from the statement that among his scholars were Pericletus, Canachus (the second), Asopodorus, Alexis, Aristides, Phryno, Dino, Athenodorus, and Demeas. (Plin., *Hist. Nat.*, xxxiv. 8.) Unfortunately no work known to be the production of Polycletus exists by which the moderns can judge of the merit of this artist.

In addition to his fame as a statuary, Polycletus has that of an able architect. One of the monuments of his skill in this art was a marble building erected at Epidaurus, called the Tholus. Another was a theatre, erected within the precincts of the temple of Æsculapius, also at Epidaurus. It was considered, according to Pausanias, superior, for its symmetry and beauty, to any theatre extant.

The second Polycletus (Argivus) was the brother and scholar of Naucydes. It is thought likely that this artist was the author of two celebrated statues described by Pausanias; namely, the Jupiter Philius, erected at Megalopolis, and the Jupiter Milichius, a marble statue at Argos (Paus., lib. viii., 31, and ii., 20); as well as of some bronze tripods dedicated at Amyclæ. For further particulars respecting Polycletus, and works produced by artists so called, the reader is referred to Pliny (*Hist. Nat.*), Pausanias, Junius, and Sillig (*Catal. Artificum*), Em. David, and other writers on antient art.

An antient Greek epigram alludes to Polycletus, a Thasian; but there is no account of him among the artists of antiquity.

POLYCOTYLEDONOUS plants are those which have more than two cotyledons. Instances of this occur in the Brassicaceous order, in Lepidium and Schizopetalum; in the Boraginaceous order, in the genus Amsinkia, and especially in Coniferous plants. They are however regarded as analogous, in the latter case, to verticillate leaves, as compared with those which are opposite; and in the other instances they may be produced, by the division of the ordinary cotyledons into two or more lobes each. All such plants are referred to the Dicotyledonous type.

POLY'CRATES. [Samos]

POLYDECTUS, the name given by M. Milne Edwards to a genus of small *Brachyurous Crustaceans*, placed by him in his tribe *Corystians*, which tribe, in his opinion, forms the passage between the *Cancerians* and *Calappians* on one side and the *Anurous Decapods* on the other. He places *Polydectus* between *Thia* and *Corystes*. [Corystes, vol. viii.] Example, *Polydectus cupuliferus* (*Pilumnus cupuliferus*, Latr.).

POLYDONTES, De Montfort's name for a genus of *Helicidæ*. The shape of the shell resembles Carocolla, and the nearly circular aperture is surrounded with obtuse tubercular teeth. Mr. Swainson makes it a subgenus of *Lucernella*, Sw., and places it in his second subfamily *Lucerninæ*. (*Treatise on Malacology*.) Example, *Polydontes Imperator*.

POLYDORE VIRGIL. [Virgil.]

POLY'GALA SE'NEGA (*Virginian Snake-Root*), a perennial plant, native of several parts of North America, but the best is found in Virginia, having a rootstock, about the thickness of a quill, twisted, and generally branched, the rootlets being esteemed the most powerful part. The bark is of a dirty yellow colour; the odour disagreeable; the taste, at first, mucilaginous, then sweet, then acid, but at last acrid, causing an unpleasant feeling of permanent irritation in the throat. The powder of the root causes sneezing: it contains two sorts of resin, a very bitter principle (polygalin), and the acrid principle (senegin, which, when isolated, is insoluble in water, but perfectly so when in its natural state of combination with the extractive matter of the root), isolusin, and polygalate of iron and potassa, &c. It possesses very manifest stimulating and tonic powers, especially over all secreting organs, whether the skin, mucous membranes, or glands. By its irritating qualities it can act as an emetic, but it is rarely used except in croup. In some forms of indigestion, attended with inadequate secretion of saliva, it is extremely useful, but it is permanently serviceable in the chronic ophthalmia of strumous children, as it promotes increased action of the glands. As a gargle, it is an efficacious remedy against the hoarseness occasioned by common colds.

POLYGALA'CEÆ are polypetalous plants, with irregular flowers, a definite number of hypogynous stamens, arranged in two parcels; anthers opening by pores, and a simple superior ovary, becoming, when ripe, a drupe or capsule. In all Polygalaceæ proper the corolla is irregular, and composed of petals irregularly consolidated into the form of a keel, while the calyx has two of its lobes much larger than the others, and coloured like petals. The order consists of herbaceous plants or shrubs, in which bitter qualities are predominant; many of the species are sufficiently beautiful to be cultivated as objects of ornament.

POLYGAMOUS plants are those which have male and hermaphrodite, or female and hermaphrodite, or both female, male, and hermaphrodite flowers on the same or different individuals.

POLY'GAMY is the name of the custom according to which a man may have more than one lawful wife at a time, which custom prevails in several countries. Polygamy has existed in Asia from time immemorial, under the old religions, and Mohammedanism adopted and confirmed the custom. Montesquieu pretends that polygamy in the East is the consequence of the greater number of female births in that country; but this surmise is by no means proved. Another and a more plausible reason may be found in the premature old age of the female sex in some countries. Niebuhr, in his 'Travels in Arabia,' gives a curious conversation which he had with an Arab on the subject.

The Romans did not practise polygamy, nor did the Greeks. The barbarous nations, on the contrary, that is to say, those who were not Greeks or Romans, practised polygamy, with the exception of the Germans, 'who alone,' says Tacitus, 'among all the barbarians, are content with a single wife.' (*German.*, 17.)

In the scriptures we find instances of polygamy recorded before the flood. (*Genesis*, iv. 19.) It was common in the patriarchal times, and we have the instance of Jacob marrying two sisters. By the law of Moses it appears to have been tolerated. (*Exodus*, xxi. 9, 10, and *Deuteronomy*, xxi. 15.) But in the time of our Saviour, no indication appears of its being common among the Jews. Repudiation, or divorce, however, was frequent, and our Saviour (*Matthew*, xix. 9) reprobates the custom. St. Paul speaks always of marriage in terms implying the union of one man with one woman. In Christian countries, Polygamy has been long since universally forbidden, both by the church and by the civil law, under severe penalties, which in some countries amounted to death. In England, it is an offence punishable with transportation, or imprisonment for two years, for a married man or married woman to marry another person during the lifetime of the first wife or husband.

The Koran allows a man to have four legitimate wives; but it is only the rich who avail themselves of this permission. The Arabs are generally content with one wife.

Polygamy is different from modern concubinage, which is the cohabitation of man and woman unsanctioned by any legal ceremony or legal form.

POLYGA'STRICA, one of the two great divisions of Infusorial animalculæ proposed by Ehrenberg and adopted by many subsequent writers as a distinct class of the zoophytic division of the animal kingdom. In the 'Cyclopædia of Comparative Anatomy' (article 'Animal Kingdom'), the Polygastrica form the first and lowest of five groups of Cycloneurose animals. This appears to us the best view yet made public.

Enough has been said in the article Infusoria of the general results of M. Ehrenberg's long-continued and successful scrutiny of the minute organization of these animated atoms, we shall therefore here append an abstract of the classification which he has proposed, and which has been generally followed, except with regard to the substitution which he makes of Phytozoaria for Infusoria.

Class *Phytozoaria polygastrica*.

Swimming animals, without vertebræ, apodal, having sometimes a tail, and very often scattered vibratory or rotatory ciliæ; having no heart, but vessels extremely delicate (ténus), reticulated, transparent, and deprived of proper movement; often rudimentary eyes, with red pigmentum, indicating a nervous system, which however is not apparent; mouth nude or surrounded by vibratory ciliæ, and communicating with several ventricules; the phalanx apparent, and generally unarmed; no branchiæ; organs of generation filiform, reticulated, and granular; no distinct male organ; gifted with power of reproduction by spontaneous division.

Legion 1. Anentera.
Mouth communicating with several stomachal vesicules; no anus, no intestinal tube.

Order 1. Nuda.
Body without envelope.

Order 2. Loricata.
Body enveloped.

Section 1. Gymnica.
Body not ciliated; mouth with or without ciliæ; no pseudo-pediform prolongations.

§ 1. Gymnica nuda.
Fam. 1. Monadina.
Form of the body constant, reproduction by simple transverse division.
A. Without tail.
a. No eyes.
* Mouth truncate, terminal and turned forwards in swimming.
† Individuals solitary.
Genus *Monas*.
†† Individuals solitary when young, afterwards aggregated and again liberated.
Genus *Uvella*.
††† Individuals solitary when young, dividing crucially.
Genus *Polytoma*.
** Mouth direct, truncate, and turned different ways in the animal's movements.
Genus *Doxococcus*.
*** Mouth oblique, without edges, and bilobate.
Genus *Chilomonas*.
aa. One red eye.
Genus *Microglena*.
B. With a tail.
b. Body cylindrical.
Genus *Bodo*.
bb. Body angular.
Genus *Urocentrum*.
Fam. 2. Vibrionina.
Body elongate, constant in shape, dividing into many parts, mouth terminal?
A. Body filiform, cylindrical, bending itself in undulations.
Genus *Vibrio*.
B. Body filiform, rigid, and rolling itself in spiral.
b. The spiral plane.
Genus *Spirodiscus*.
bb. The spiral helical.
Genus *Spirillum*.
C. Body oblong, fusiform, or filiform, neither undulated nor turned spirally.
Genus *Bacterium*.
Fam. 3. Astasiæa.
Body elongated, becoming polymorphic by contraction, often cylindrical or fusiform, and spontaneously dividing itself in longitudinal or oblique direction.
A. No vestiges of eyes.
Genus *Astasia*.
B. Distinct rudimentary eyes.
b. One eye.
* A tail.
Genus *Euglena*.
** No tail.
Genus *Amblyophis*
bb. Two eyes.
Genus *Distigma*.

§ 1. Gymnica loricata.
Fam. 1. Cryptomonadina.
Envelope membranous, subglobular, and oval.
A. Simple.
a. No eyes.
* Mouth ciliated.
Genus *Cryptomonas*.
** Mouth nude.
Genus *Gyges*.
aa. With a red eye.
Genus *Lagenula*.
B. Compound, or reproducing by internal division.
Genus *Pandorina*.
Fam. 2. Closterina.
Envelope round, when rigid, separating spontaneously into two or four parts by transverse divisions, and open at each end.
Genus *Closterium*.

Section 2. Epitricha.
Body ciliated; mouth ciliated or nude; no pseudo-pediform prolongations.

Epitricha nuda.
Fam. 4. Cycladina.
A. Body with vibratory ciliæ.
a. Ciliæ in simple rows, longitudinal or circular.
Genus *Cyclidium*.
aa. Ciliæ scattered.
Genus *Pantotrichum*.
B. Body deprived of ciliæ, but furnished with hairs not vibratile.
Genus *Chætomonas*.

Epitricha loricata.
Fam. 3. Peridina.
A. Simple.
Genus *Peridinium*.
B. Compound, reproduced by interior division and rupture of the envelope.
b. No eyes.
* Envelope compressed.
Genus *Gonium*.
** Envelope globular.
† Ciliated.
Genus *Volvox*.
†† Tentaculated.
Genus *Sphærosira*.
bb. With eyes.
Genus *Eudorina*.

Section 3. Pseudopodia.
Body furnished with variable pseudo-pediform prolongations.

Pseudopodia nuda.
Fam. 5. Amæbæ.
Genus *Amæba*.

Pseudopodia loricata.
Fam. 4. Bacillaria.
The envelope dividing with the animal.
A. Free, never fixed.
a. Solitary or agglomerated.
* Envelope oblong.
Genus *Navicula*.
* Envelope wider than long
Gen. *Euastrum*.
aa. United in form of ribands, polymorphous: the individuals of the group have some freedom of movement without becoming detached; cuirass equally thick throughout, and prismatic.
Gen. *Bacillaria*.
aaa. United in bundles and not polymorphous, afterwards disunited.
Gen. *Fragillaria*.
aaaa. United in a fan shape, without foot: cuirass thicker in front.
Gen. *Exilaria*.
B. Fixed when young, afterwards free.
b. Sessile.
Gen. *Synedra*.
bb. Pedicellated, often dichotomous by ramification; body reduced below, cuneiform.
Gen. *Gomfonema*.
bbb. Pedicellated, often dichotomous; body contracted towards each extremity, subfusiform.
Gen. *Cocconema*.
bbbb. Pedicellated, united in a fan shape, and often dichotomous.
Gen. *Echinella*.
Fam. 5. Arcellina.
Envelope undivided.
A. Envelope urceolate.
Gen. *Difflugia*.
B. Envelope scutelliform.
Gen. *Arcella*.

Legion 2. Enterodela.

Mouth and anus distinct, opening into an intestine, round which are grouped the stomachal vesiculi.

Section 4. Anopisthia.

Mouth and anus contiguous.

Anopisthia nuda.

Fam. 6. *Vorticellina.*

A. Body pedicellated, fixed, afterwards detached, becoming often dichotomous.

a. Pedicle simple or branched, contracting into a spiral.

* Pedicle solid, the interior muscle indistinct.
Gen. *Vorticella.*

** Pedicle tubular, the interior muscle often distinct, becoming arborescent by the spontaneous divisions of the animal.

† Animalcula of the same group similar.
Gen. *Carchesium.*

†† Animalcula dissimilar in the same group.
Gen. *Zoocladium.*

aa. Pedicle not contracting in spiral, rigid, with no interior tube.
Gen. *Epistylis.*

B. Body not pedicellated and free.

b. Ciliæ in a single crown.
Gen. *Trichodina.*

bb. Ciliæ in a spiral row conducting to the mouth.
Gen. *Stentor.*

Anopisthia loricata.

Fam. 6. Ophridina.

A. Body surrounded by gelatine and not pedicellated.
Gen. *Ophrydium.*

B. Body enclosed in a membranous sheath.

b. Pedicellated.

* Sheath sessile.
Gen. *Tintinnus.*

** Sheath pedicellated.
Gen. *Cothurnia.*

bb. Not pedicellated.
Gen. *Vaginicola.*

Section 5. Enantiotreta.

Mouth and anus terminal and opposite, reproduction effected by transverse division.

Enantiotreta nuda.

Fam. 7. Enchelia.

A. Mouth, terminal, direct, obtuse, generally ciliated; division of the body transverse.

a. Body not ciliated, nor with hairs.

* Simple.
Gen. *Enchelys.*

** Double.
Gen. *Disoma.*

aa. Body with vibratory ciliæ.
Gen. *Holophrya.*

aaa. Body with ciliæ not vibratory.

* Subglobular.
Gen. *Actinophrys.*

** Disciform.
Gen. *Trichodiscus.*

B Mouth terminal, oblique, often ciliated.

b. Body without cilia.

* No prolongation of the anterior part.
Gen. *Trichoda.*

** Anterior part prolonged into the form of head and neck.
Gen. *Lachrymaria.*

bb Body ciliated.
Gen. *Leucophrys.*

Enantiotreta loricata.

Fam. 7. Colepina.

Envelope oval or cylindrical.
Gen. *Coleps.*

Section 6. Allotreta.

Mouth and anus terminal and opposite, reproduction effected by longitudinal and transverse divisions.

Allotreta nuda.

Fam. 8. Trachelina.

Mouth inferior, anus terminal.

A. Mouth unarmed.

a. No circle of ciliæ in front.

* Upper lip or front elongate, cylindrical or depressed, prolonged into a narrow trumpet form
Gen. *Trachelius.*

** Upper lip short, depressed, and dilated obliquely.
Gen. *Loxodes.*

*** Upper lip compressed, subcarinate, or tumid.
Gen. *Bursaria.*

aa. Front with a ring of ciliæ.
Gen. *Phialina.*

B. Mouth armed with hooks.
Gen. *Glaucoma.*

Fam. 9. Ophryocercina.

Anus inferior, mouth terminal.
Gen. *Ophryocercus.*

Allotreta loricata.

Fam. 8. Aspidiscina.

Gen. Aspidiscia.

Section 7. Katotreta.

Mouth and anus not terminal, reproduction as in the preceding section.

Katotreta nuda.

Fam. 10. Kolpoda.

Body smooth or ciliated, unarmed.

A. No eyes.

a. A short retractile proboscis.

* Body partially ciliated.
Gen. *Kolpoda.*

** Body ciliated obliquely all over.
Gen. *Paramæcium.*

aa. No proboscis.

* Front and tail contracted.
Gen. *Amphileptus.*

** Front oblong, tail contracted.
Gen. *Uroleptus.*

B. With eyes.
Gen. *Ophryoglena.*

Fam. 11. Oxytrichina.

Body ciliated and hairy, or armed with styles or straight spiaclæ and hooks.

A. Body hairy, no styles or hooks.
Gen. *Oxytricha.*

B. Body with hooks and no styles.
Gen. *Kerona.*

C. Body with styles and no hooks.
Gen. *Urostyla.*

B. Body with styles and hooks.
Gen. *Stylonichia.*

Katotreta loricata.

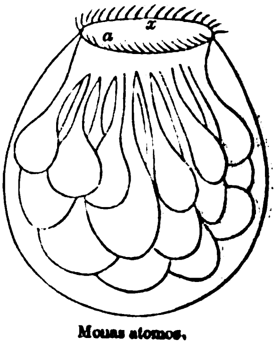
Fam. 9. Euplota.

Body armed with hooks.

A. Head indistinct.
Gen. *Euplotes.*

B. Head separated from the body by a contraction.
Gen. *Discocephalus.*

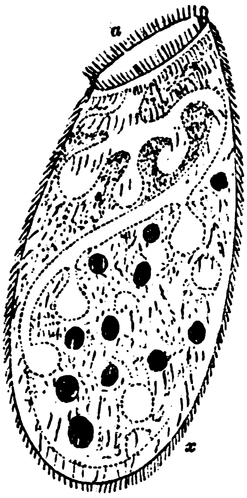
Fig. 1.



Monas atomos.

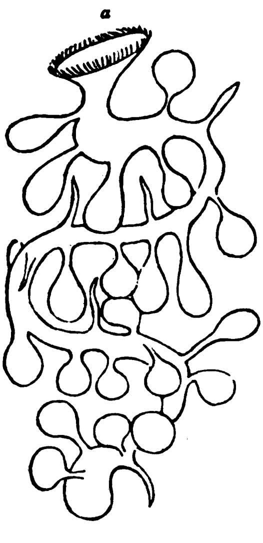
In illustration of these minute animals, we subjoin figures of Monas atomos as an example of the gastric structure of the Anentera, and of Leucophrys patula as an example of the Enterodela. The intestinal system of Leucophrys is also given separately. *a* in each case marks the situation of the mouth, and *x* that of the anus.

Fig. 2.



Leucophrys patula, with some of the gastric cavities full of food.

Fig. 3.



Intestinal system of Leucophrys patula.

PO'LYGLOTTS (πολύγλωττα, from πολὺς, much, many, and γλῶττα, a tongue), books in several languages. The application of the word is restricted to the Bible, which being a collection of books written by various persons, at various times, and on various subjects, is called Biblia (books), and a Polyglott Bible is therefore called Biblia Polyglotta.

The idea of a Polyglott Bible seems to have been first conceived in the third century, by Origen, who spent many years of immense labour in forming the Old Testament into such a work. This is commonly called Biblia Hexapla, the Bible in six columns. The six columns consisted of 1, the Hebrew text; 2, the Hebrew in Greek characters; 3, the Greek version of Aquila; 4, the Greek version of Symmachus; 5, the Septuagint; 6, the Greek version of Theodotion. These six columns went through the work; but some portions were in eight columns and others in nine, and with reference to these portions it is called Octapla and Enneapla. Considered apart from the Hebrew, and the Hebrew in Greek characters, it is called Tetrapla, the Bible in four columns. Though two languages only were used in the formation of this work, it might not improperly be called a Polyglott. It is to be lamented that, except in the Septuagint, only a few fragments of Origen's performance have come down to us. These were published by Montfaucon, in 2 vols. folio, Paris, 1714, under the title 'Hexaplorum Originis quae supersunt.'

Among the moderns, Aldus Manutius first planned a Polyglott in Hebrew, Greek, and Latin; but he never printed more than one sheet, a copy of which, supposed to be the only one in existence, is in the royal library at Paris. Its date is 1501. Since that time various Polyglotts have been published, of which the principal are the following:

I. The Complutensian Polyglott. This was printed at Complutum, the Latin name of Alcala de Henares in Spain. It was begun in 1502, and finished in 1517, but it was not published before 1522. It was patronised by Cardinal Francis Ximenes [CISNEROS], who employed seven learned men competent for the undertaking, and who munificently defrayed the entire expenses of its publication. This noble work was dedicated by its patron to Pope Leo X. It is in six volumes, folio. In the Old Testament each page consists of three columns, the left-hand page presenting the Hebrew, the Vulgate, and the Septuagint, and the right-hand the Septuagint, the Vulgate, and the Hebrew, with Hebrew primitives in the outer margin, and a supralineary Latin interpretation of the Septuagint. At the lower part of the page is a Chaldee paraphrase with a Latin interpretation, in two columns. In the New Testament each page has two columns, consisting of the Greek text and the Latin Vulgate with marginal references. The Greek Testament of this Polyglott is remarkable as being the first complete edition ever printed. Besides a variety of prefatory matter in the first volume, the whole of the sixth volume, with the concluding part of the fifth, consists of several distinct performances, making a large apparatus of elementary biblical literature. Of the Complutensian Polyglott 600 copies only were printed, and one is seldom met with except occasionally in public libraries.

II. The Antwerp Polyglott. This was printed by Christopher Plantin, at Antwerp, 1569-1572, in eight vols. folio. The editor was Arias Montanus, who had about sixty assistants. The work was published under the sanction of Philip II., king of Spain, who is reported to have defrayed its expenses, though some are of opinion that he merely lent the money to Plantin, and demanded its repayment in such a manner as to involve him in very great distress. The whole of the Complutensian Polyglott is comprised in this of Antwerp, besides another Chaldee paraphrase of a part of the Old Testament, a Syriac version of the New Testament, and the Latin translation of Santes Pagninus, altered by the editor, Arias Montanus. The Old Testament is in four columns, two in each page, a Latin interpretation of the Septuagint forming one of the columns, with a Chaldee paraphrase on the lower part of the left-hand page, and a Latin interpretation on that of the right. In the New Testament the versions are similarly arranged, Syriac being in place of the Hebrew, and the Latin of Pagninus answering to the Latin interpretation of the Septuagint. The types are bold and finely formed, and the paper is of a yellowish cast and of excellent quality. The sixth, seventh, and eighth volumes consist of lexicons, grammars, and other aids for understanding the contents of the preceding volumes. Of this Polyglott 500 copies only were printed, and the greater number of these were lost in being conveyed by sea to Spain, so that it is more rare than even its predecessor of Complutum.

III. The Parisian Polyglott. This was printed at Paris, by Antony Vitré, 1628-1645, in 10 vols. large folio. The editor was Guido Michael le Jay, who at this time was a layman, but afterwards became an ecclesiastic. He had several learned associates, and he might have had the patronage of Cardinal Richelieu, but, refusing this favour and venturing to publish the work at his own expense, he brought ruin upon himself. This splendid performance contains all that is in the two preceding Polyglotts, with the addition of an Arabic version of the Old and New Testament, a Syriac version of the former, and the Samaritan Pentateuch. These additions however are made separately, so that, though the Parisian Polyglott contains portions of the Bible in seven languages, its pages do not exhibit at one view more than the Antwerp Polyglott. These ten volumes, in imperial folio, present attractions of no ordinary kind. The paper, though perhaps not so fine as that of the Antwerp Polyglott, is beautiful; the types are large, clear, and elegantly formed; the engraver's art moreover is appropriately displayed in furnishing occasional embellishments; in a word, the Parisian Polyglott is altogether as magnificent a work as can well be conceived.

IV. The London Polyglott. This was edited by the learned Brian Walton, who became afterwards bishop of Chester. It is in 6 vols., large folio. It was published by subscription, and the volumes came out in the following order:—the first volume in September, 1654; the second in July, 1655; the third in July, 1656; and the last three in 1657. 'And thus,' says Dr. Twells (*Life of Pocock*), 'in about four years was finished the English Polyglott Bible, the glory of that age, and of the English church and nation, a work vastly exceeding all former attempts of that kind, and that came so near perfection as to discourage all future ones.' Some portions of this Polyglott are printed in seven languages, all open at one view. No one book is given in nine languages; but nine languages are used in the course of the work, namely, Hebrew, Chaldee, Samaritan, Syriac, Arabic, Persian, Ethiopic, Greek, and Latin. A vast body of introductory matter is in the first volume, and the sixth is made up of various readings, critical remarks, &c. Brian Walton was assisted by a number of men who formed a constellation of oriental and general scholars, such as perhaps have appeared together at no other period during the whole history of our country. One of these men was Dr. Edmund Castell, who published his 'Lexicon Heptaglotton' in 1669, 2 vols. folio. This is a lexicon of the seven oriental languages occurring in Walton's Polyglott, and it has grammars of all these languages prefixed. It generally accompanies the Polyglott, which can hardly be pronounced complete without it. Walton's work is by no means equal in appearance to the three preceding Polyglotts, but in point of solid usefulness to the biblical scholar it is far beyond any one of them. The eight volumes form an extraordinary collection of aids for studying the original scriptures. As the London Polyglott is frequently found in private libraries, a more minute description of its contents appears to be unnecessary. Its history is recorded at length in Archdeacon Todd's 'Memoirs of the Life and Writings of the Right Rev. Brian Walton, D.D., lord bishop of Chester,' 2 vols. 8vo., London, 1821, a work which comprises also notices of all Walton's coadjutors.

V. Bagster's Polyglott. This work was published by the enterprising bookseller by whose name it is known, in 1 vol. folio, London, 1831. The Old Testament is in eight languages, and the New Testament in nine. Eight languages are exhibited at once upon opening the book. The languages are Hebrew, Greek, English, Latin, German, Italian, French, Spanish, and Syriac, the New Testament being given in the last language as an appendix. To these are added the Samaritan Pentateuch in Hebrew characters; the notes and readings of the Masorites; the chief variations of the Vatican text of the Septuagint (which is followed in this Polyglott), and of the Alexandrian as given by Grabe, Oxford; and of the Greek Testament the whole of the selected various readings given by Griesbach in his own edition of 1805. Prefixed to the work are fifty pages of prolegomena in Latin, by Professor Lee of Cambridge. The types are small, but clear and elegant, and the paper is of excellent quality. The whole volume presents a very handsome appearance.

On the subject of Polyglott Bibles in general, the reader will be gratified by consulting Horne's *Introduction*; Butler's *Horæ Biblicæ*; Clarke's *Bibliographical Dictionary*; Le Long's *Bibliotheca Sacra*, improved by Masch.

POLYGNO'TUS, one of the most celebrated of the antient painters. He was a native of Thasos: son and pupil of Aglaophon, a painter of that island. Pliny merely says that Polygnotus lived before the 90th Olympiad (xxxv. 9); but from Plutarch's account of his friendship for Cimon and love for Cimon's sister Elpinice (Plut., *Cim.*, c. iv.), it would seem probable that he flourished at Athens at least as early as the 80th Olympiad (B.C. 460). Thasos was reduced by the Athenians, after a war of three years, in 463 B.C., and it is likely enough that Polygnotus then left his native country, and accompanied its conqueror Cimon on his return to Athens. A story told by Plutarch (*Cim.*, c. xiv.) would represent Elpinice as no longer young in the year 463: if so, it is not probable that she would have retained sufficient beauty, at a later period, to be introduced by the artist into his painting in the Pœcile. Polygnotus obtained the rights of citizenship at Athens: how long he continued to paint we have no means of knowing. Pliny describes him as 'the first who painted women with transparent drapery, and covered their heads with variegated caps. He first began to open the mouth, and show the teeth of his figures, and to give them an expression of countenance different from the antient stiffness.' (Plin., xxxv. 9.) Polygnotus and Micon were the first artists who employed the 'sil,' or yellow colour found in the Attic silver mines. (Plin., xxxiii. 13.) The same painters used a black or blue colour prepared from grape husks ('tryginon'). (Plin. xxxv. 6.) Some of the works of Polygnotus were executed in the encaustic method. (Plin., xxxv. 11.) Cicero (*Brutus*, xviii.) mentions him as one of the masters who used the four old colours. [PAINTING.] Aristotle (*Polit.*, viii. 5) calls him ἠθικός, one who conveyed a notion of moral qualities and of character by his works, and in the 'Poetics' (15) he contrasts this ethic character of Polygnotus with the absence of such a quality in Zeuxis; in cap. 4 he says that Polygnotus made his figures superior, Pauson inferior, and Dionysius similar, to nature. It would follow from all this that Polygnotus held an analogous place in the history of antient art to that occupied by some of the early Florentine masters in modern painting. Perhaps Fra Angelico or Masaccio would be a fair parallel; always bearing in mind that painting among the antients was essentially statuesque in its character, and therefore, at an equivalent stage of development, the drawing of the figure would be much further advanced than in Italian art.

The principal works of Polygnotus enumerated by the antients are—

1. The pictures in the Lesche at Delphi, of which Pausanias (x. 25) has left an elaborate description. The subjects were—the Capture of Troy, the Return of the Greeks, and the νεκυία, or Visit of Ulysses to the Shades. It would seem, from the account of Pausanias, that names were attached to most of the figures, as we see them often inscribed on the vases. The variety of age and sex portrayed, and the feelings of some of the personages, imply a discrimination of character and a power of expression, such as we should expect from the reputation of the artist. Thus Hector was represented seated, clasping with his hands his left knee, and with an expression of deep melancholy. Penthesilea appeared to contemplate Paris with contempt and scorn (x. 31). Lucian (*Imag.*, 7) mentions the figure of Cassandra, as showing delicacy and beauty of the brow, and the blush of the cheek (ὀφρύων τὸ ἐπιπρεπὲς καὶ παρειῶν τὸ ὑπερευθές). A German artist, Riepenhausen, published some designs formed on the description by Pausanias of these works of Polygnotus, and Göthe (vol. xliv., 97) has written an essay on the subject.

2. The Pœcile at Athens. The subject probably was the Destruction of Troy. (Plut., *Cim.*, iv.)

3. A painting in a building near the Propylæa at Athens. (Paus., i. 22, 6.)

4. The Marriage of the Daughter of Leucippus in the temple of the Dioscuri at Athens. (Paus., i. 18, 1.) If this work were extant, a comparison of it with the noble picture of nearly the same subject by Rubens in the Munich gallery would probably afford as striking a contrast between antient and modern art as can be imagined.

5. It seems likely that Polygnotus painted the temple of Theseus, at least if we adopt the emendation ἐν τῷ Θησέως ἱερῷ, for ἐν τῷ Θησαυρῷ, in Harpocration.

6. A picture representing Ulysses after the Slaughter of the Suitors, in the temple of Minerva Area at Platæa. (Paus., ix. 4, 1.)

7. The Walls at Thespiæ, painted by Polygnotus and restored by Pausias. (Plin. xxxv. 11.)

It is very difficult for us to form any distinct idea of what the effect of the works of Polygnotus must have been. From the expressions used by Aristotle, they probably possessed much calm dignity and an absence of all exaggeration. We must not imagine that they showed the complicated composition, the masses of light and shade, the variety of colour, or the accurate perspective of the best modern masters. An attentive observation of the finest of these vases, which still retain traces of the severer style of the art united with good execution, will convey the best general notion of the works of such an artist. As in sculpture, no accessories probably appeared, except such as were absolutely necessary for understanding the story, and essential to the attitudes of the figures. (Sillig, *Catalogus Artificum*; Müller, *Handbuch der Archæologie und Kunst*; Müller, *De Vitæ et Operibus Phidiæ*; Goethe, vol. xliv., p. 97.)

POLYGON, REGULAR. [REGULAR FIGURES; REGULAR SOLIDS.]

PO'LYGON and **POLYHEDRON.** The word polygon means figure of several angles, and polyhedron means solid of several faces: the first is used for a plane bounded by straight lines, the second for a solid bounded by planes. We shall in this article state the general properties of both kinds of figures, reserving the particular consideration of those which have equal sides or equal faces for the articles REGULAR FIGURES and REGULAR SOLIDS.

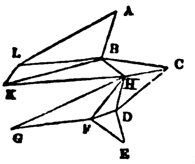
The elements of Euclid confine themselves to convex polygons, and to a limited number of polyhedrons. The most general propositions with respect to polygons as polygons, that is, which are true whatever the number of sides may be, are as follows: they are either in the 'Elements', or immediately deducible from them.

1. The internal angles of a polygon of n sides are together always equal to $n-2$ pairs of right angles. See REVOLUTION OR ROTATION for the full meaning of this proposition.

2. When a figure of an even number of sides is inscribed in a circle, the sum of the first, third, fifth, &c. angles is equal to the sum of the second, fourth, sixth, &c. angles. But when a figure of an even number of sides is *described* about a circle, for angles read sides in the preceding property.

3. Any one side of a polygon is less than the sum of all the others.

The first-mentioned theorem remains true beyond the limits of Euclid's meaning, namely, as long as the figure of n sides can in any way be divided into $n-2$ triangles: that is, in fact, as long as no side of the figure crosses any other side. Thus the adjoining polygon of 10 sides, being divisible into 8 triangles, has the sum of all its angles equal to 16 right angles, four of these angles being each greater than two right angles.



To make a rule however which shall connect the angles of any polygon whatsoever, that is, of any figure, however irregular, in which a point returns by a succession of straight lines to the point from whence it set out, would be difficult in the ordinary way of measuring angles. On this subject see SIGN.

A polygon of n sides or edges has one face, and n angular points or corners: that is, the number of faces and corners together exceed the number of edges by 1. On one side of the polygon let another polygon be described: it is then obvious that the two polygons have two corners in common, but only one edge, or else three corners and two edges, &c.; that is, whatever *new* corners are added, one more new edge is added: or, since one face is added, the total number of faces and corners is increased by the same as the number of edges. The same may be proved of every new polygon which has one or more sides in common with any of the old ones: and since at the outset the number of corners and faces exceeds the number of edges by 1, and since every alteration adds the same to both sides of this equation, it remains true throughout. Whence the following theorem: let any number of polygons, in the same plane or not, be so connected that each has one side or more in common with one or more of the others: call each polygon one face; each side, to how many polygons soever it may belong, one edge; and such angular point, no matter how many angles may be collected there, one corner: the number of faces and corners will always exceed the number of edges by one.

Let there be a solid polyhedron, and beginning from one given face, annex the others successively: the preceding theorem will remain true, as long as each face which is added adds one or more new edges. But it is obvious that when the polyhedron is completely finished, with the exception of the last face, the completion of the solid, by counting the last face, adds no new edge or edges, these having been completely laid down in former faces. Hence,[*] in every solid polyhedron, the number of faces and corners exceeds the number of edges by *two*.

Again, on a given face of a polyhedron as a base, let a second polyhedron be constructed, and on a given face of that a third, and so on, it being permitted to include several faces from different polyhedrons among the faces of the new one. In the part of each new polyhedron which belongs to the preceding ones, as already shown, the corners and faces exceed the number of edges by one; and the same also in the new portion. But since one new polyhedron is added at every step, it follows that the new faces and corners are the same in number as the new edges and polyhedron. But at the beginning, counting one polyhedron, the faces and corners outnumber the edges and polyhedron by one (since they outnumber the edges by 2): and since both sides of this equation receive the same accession for every new polyhedron, it remains always true: that is, the total number of corners and faces in any system of polyhedrons, each of which has one or more faces in common with others, exceeds the total number of edges and polyhedrons by 1.

In every face of a polyhedron take any point, which for abbreviation we may call the centre of that face. Join the centre of each face with the centres of the adjoining faces; we have thus a new polyhedron, and the points may be so taken, that those lying in the faces which meet at any corner, shall all be in the same plane. The new polyhedron has obviously as many corners as the old one had faces; and as many faces as the old one has corners: the number of edges being the same in both: and if we call a corner triangular, quadrangular, &c., according as three, four, &c. angles meet there, the new solid has as many triangular, &c. faces, as the old solid has triangular &c. corners; and vice versâ. These polyhedrons may be called conjugate to one another.

Thus there is a triangular tetrahedron (four-faced solid) with four triangular corners: consequently the conjugate solid is another tetrahedron of the same kind. The quadrangular hexahedron (of six four-sided faces) has 8 triangular corners: the conjugate solid has therefore 8 triangular faces, and six quadrangular corners (the triangular octahedron). The pentagonal dodecahedron (having 12 five-sided faces) has 20 triangular corners: the conjugate solid has therefore 20 triangular faces and 12 pentagonal corners (the triangular icosahedron). The solids mentioned in this paragraph are those which may be made of equilateral and equiangular faces. [REGULAR SOLIDS.]

Again, a solid can be formed with 14 quadrangular faces, having 8 triangular corners and 8 quadrangular ones: its conjugate solid has therefore 8 triangular and 8 quadrangular faces, with 14 quadrangular corners; the number of edges in both being $8+8+14-2$, or 28.

Let F_3, F_4, F_5, &c. be the number of triangular, quadrangular, pentagonal, &c. faces in a solid, and C_3, C_4, C_5, &c., the number of triangular, quadrangular, pentagonal, &c. corners. Let F, C, E be the total number of faces, corners, and edges; then we have

$$F = F_3 + F_4 + F_5 + \ldots\ldots \quad (1)$$
$$C = C_3 + C + C_5 + \ldots\ldots \quad (2)$$

Again, since $3F_3 + 4F_4 + \ldots\ldots$ is the total number of sides of all the faces, before they are joined, and since the junction joins each with another, we have half the preceding for the number of edges, or

$$2E = 3F_3 + 4F_4 + 5F_5 + \ldots \quad (3)$$
$$2E = 3C_3 + 4C_4 + 5C_5 + \ldots \quad (4)$$

But $F + C = E + 2$, whence we deduce

$$2C = 4 + F_3 + 2F_4 + 3F_5 + \ldots \quad (5)$$
$$2F = 4 + C_3 + 2C_4 + 3C_5 + \ldots \quad (6)$$

Hence $F_3 + F_5 + \ldots\ldots$ and $C_3 + C_5 + \ldots\ldots$ must be even numbers; for if these be subtracted from the even numbers 2 C and 2 F, it will be seen that even numbers are left: or the number of odd-sided figures must be even, and also the number of odd-angled corners. Moreover the number of corners must be made up of (1) a couple; (2) half as many as there are odd-sided faces; (3) 1 for every quadrangle, 2 for every hexagon, 3 for every octagon, &c.; and the same will be true if we write faces for corners, and corners for faces.

Since every face has at least three sides, and every corner at least three angles, 2 E cannot fall short of 3 F, nor of 3 C. Hence, neither $4E - 6F$, nor $4E - 6C$ can be negative, that is, neither of the following can be negative:

$$3C_3 + 2C_4 + C_5 - 12 - C_7 - 2C_8 - 3C_9 - \ldots\ldots \quad (7)$$
$$3F_3 + 2F_4 + F_5 - 12 - F_7 - 2F_8 - 2F_9 - \ldots\ldots \quad (8)$$

Hence it appears that there must be either triangular, quadrangular, or pentagonal faces, and either three-angled, four-angled, or five-angled corners. Call these the *essential* faces and corners. Hence the following readily follows:

---

[*] The present mode of demonstrating this well known theorem was given, for the first time to his knowledge, by the author of this article, in the *Phil. Mag.*; but he has since found that it is substantially contained (under mathematical symbols which rather conceal its simplicity) in a memoir by M. Cauchy, in the 'Journal de l'Ecole Polytecnique.'

If the essential faces be all triangles, there must be 4 at least; if all quadrangles, 6 at least; if all pentagons, 12 at least: and the same of the corners. If the non-essential faces be all hexagons, or the non-essential corners six-angled, it would appear* that the minimum number of essential faces and corners need not be increased, how many hexagons soever, or six-angled corners, there may be.

If all the corners be three-angled, we have $2E = 3C$, or (8) vanishes. If then all the faces be of sides not exceeding six, we have

$$3F_3 + 2F_4 + F_5 = 12.$$

Similarly, if all the faces be triangular, and the corners nowhere more than six-angled, we must have

$$3C_3 + 2C_4 + C_5 = 12.$$

Hence it follows that when all the corners are three-angled, and all the faces either pentagons or hexagons, the number of pentagons can be neither more nor less than 12: also that when all the faces are triangles, and all the corners five angled or six-angled, the number of five-angled corners can be neither more nor less than 12.

If all the corners be four-angled, we have $2E = 4C$, or

$$F_3 = 8 + F_5 + 2F_6 + \ldots..$$

whence there must be at least 8 triangles. And similarly, if all the sides be quadrangular, there must be at least 8 three-angled corners.

If all the corners be five-angled, we have $2E = 5C$, or

$$F_3 = 20 + 2F_4 + 5F_5 + 8F_6 + \ldots.$$

so that there must be at least 20 triangular faces. Similarly if all the faces be pentagonal, there must be at least 20 three-angled corners.

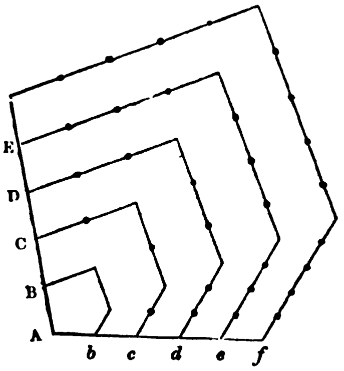
Some of the most obvious ways in which figures may be put together so as to enclose space are as follows:—

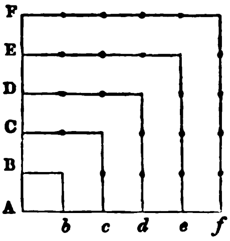
1. Two n-sided faces, joined by n quadrangles. This includes the prism and truncated pyramid, and also every quadrangular hexahedron.
2. The pyramid, with one n-sided face and n triangles.
3. The solid with n quadrangles, and $2n$ triangles, the symmetrical case of which is a prism surmounted at each end by a pyramid.
4. Two faces of n sides, and mn quadrangles, m being any whole number.
5. Twelve quadrangles so arranged that four of them are placed corner to corner, the figure being finished by four others on each side. When the quadrangles are all equilateral, this is the rhombic dodecahedron.
6. The pentagonal dodecahedron, in which there are two pentagons, each of which has another pentagon on every side, the two figures being placed together so that the projecting angles of the one fill up the re-entering angles of the other.
7. The triangular icosahedron, the conjugate solid of the last, which may be thus imagined. Let a pentagonal prism be surmounted at each extremity by a pyramid, and let the sides of the prism which join the angles of the opposite pentagons, and also a diagonal in each quadrangle, be supposed to be formed of extensible and contractible threads. Turn one of the surmounting pyramids partly round: then the sides and diagonals of the five quadrangles will no longer continue in the same plane, but will form ten triangles, which, with the ten belonging to the pyramids, complete the number required.

When the sides of a polygon are given, the polygon itself is not given, unless it be a triangle: thus there is an infinite number of quadrangles which have the same four sides. But it is very remarkable that when a solid is formed of given faces, in a given order of juxtaposition, those faces, if they form a solid at all, can only form one. This is the reason of the stability of solid figures; were it not for this, a box, for example, would require internal cross-pieces to support the sides. This remarkable property is assumed by Euclid as a part of a definition, and that improperly; since it is a new axiom.

A proof of the axiom implied in the above was given by M. Cauchy in the article already cited, and will be found in the notes to Legendre's Geometry. It is sufficient, but depends on considerations foreign to the subject as usually considered.

For the remarkable division of equal solids into symmetrically and unsymmetrically equal see **Symmetrical**: for the more general view of the nature of polygons, suggested by modern geometry, see **Transversal**: see also **Triangle**, **Regular Figures** and **Regular Solids**, **Trigonometry**, &c.





To explain the meaning of the term polygonal number [**Numbers, Appellations of**], let us take as an instance the pentagonal number. Take any pentagon BA*b*, and construct a set of pentagons, AC*c*, AD*d*, &c., double, treble, &c. of AB*b* in linear dimension. Divide the sides of each pentagon into parts, each equal to the corresponding side of AB*b*. Then if we begin with A, which is one point, and afterwards take in all the points of the first pentagon, we have 1+4, or 5 points. If we now add all the additional points of the second pentagon (including subdivision-points), we have 1+4+7 or 12 points. Take in the next pentagon, and we have 1+4+7+10, or 22 points. Hence the series 1, 5, 12, 22, &c. is called the series of pentagonal numbers; and a set of numbers is thus pointed out which may be as justly called pentagonal as the set 1, 4, 9, &c. may be called square. It must be supposed that the various sets of polygonal numbers were suggested by the square numbers.

POLYGONAL NUMBERS. [**Numbers, Appellations of.**]

POLYGONA'CEÆ are apetalous plants with triangular fruit and usually with stipules united into a tube or ocrea, through which the stem passes. Their fruit is evidently composed of three aspermous carpellary leaves joined by their edges, and surrounding a single erect ovule deriving its origin from a central placenta; and it proves in a striking manner the truth of the modern theory, that in many cases the ovules derive their origin immediately from the centre of vegetation, or the growing point, and not from the margin of carpellary leaves. The order consists of herbaceous plants more frequently than of shrubs, and a large part of them are mere weeds; as for example our docks, and wild polygonums; some however are handsome flowers, as the *Polygonum Orientale*, or Garden Persicaria, and *P. amplexicaule*; others are valuable for cooking, as the rhubarb, whose roots also furnish the important tonic and purgative drug of that name, and in some a great quantity of astringent matter is found, as in the *Coccoloba uvifera*, or seaside grape of Jamaica, from which a kind of Kino has been prepared. A species of Indian polygonum, called *tinctorium*, has recently been introduced into cultivation in Belgium as a substitute for indigo. The flour of the seeds of *Polygonum tataricum*, *fagopyrum*, and others, is made into a bad kind of bread in Lombardy and other countries.

POLY'GONUM (Zoology), Schumacher's name for a genus composed of those species of *Turbinellus* of authors with large continuous ribs, so that they look like shells with many angles or sides. Type, *Turbinellus polygonus*.

---

* Remember however that this subject is very incompletely known; and though some necessary conditions can be laid down, it has never been found out what conditions are both necessary and sufficient in order that a given number of faces may enclose space.

POLY'GONUM BISTORTA (*Great Bistort*, or *Snakeweed*). Bistort is an indigenous perennial plant, growing in woods and meadows. The root, which is the officinal part, is about the thickness of a finger, round or flattish, and much twisted, like the coils of a snake, externally dark brown, within red and fleshy. When dried, it has no smell, but a very astringent taste. Roots of plants a few years old should be taken up in spring or autumn. It consists chiefly of tannin, gallic acid, starch, and oxalate of lime. It was formerly given in diseases of debility accompanied with sanguineous or mucous discharges, and likewise fevers, especially intermittents, for the cure of which it may be combined with gentian, or sweet flag-root. It is to be regretted that an indigenous remedy of such power has fallen into neglect.

POLYGY'RA, a genus of *Helicidæ* with the shell completely discoid; no pillar; the aperture angulated and margined, and a small tooth on the inner lip.

Mr. Swainson, whose description this is, makes *Polygyra* a subgenus of *Lucernella*. (*Treatise on Malacology*.)

Example, *Polygyra septemvolva* (Sow., 'Conch. Man.,' fig. 383).

POLYHALLITE, a mineral which occurs crystallized and massive. Primary form of the crystal a right rhombic prism. Fracture uneven. Hardness sufficient to scratch carbonate of lime. Colour brick-red, pale flesh-red, and yellowish. Lustre resinous. Opaque. Specific gravity 2·769.

In the flame of a candle it melts into an opaque globule; it is soluble in water, and the solution has a saline and bitter taste.

It is found at Salzburg and also at Ischel in Upper Austria.

Analysis by Stromeyer:—

Sulphate of lime	44·74
Sulphate of potash	27·70
Sulphate of magnesia	20·04
Chloride of sodium	0·19
Peroxide of iron	0·34
Water	5·95
	98·96

POLYHEDRON. [POLYGON AND POLYHEDRON.]

POLYHISTOR, ALEXANDER, a native of Cotyæum in Phrygia, according to some, and of Miletus according to others, was a geographer and historian, who lived in the seventh century of Rome, and was taken prisoner by the Romans in the war of Sulla against Mithridates. Being purchased by Cornelius Lentulus, he was entrusted by him with the education of his children, and at last received his freedom. He then assumed the name of Cornelius, after that of his patron. He resided chiefly at Rome, and had a country-house at Laurentum, which having taken fire while he was there, he perished in the flames. He is often mentioned and quoted by Pliny the Elder, Diogenes Laertius, Clemens Alexandrinus, and Eusebius, as a man of very extensive learning, in consequence of which he was styled Polyhistor. He wrote a work in forty books, each book being the description of a distinct country. Stephanus Byzantinus mentions his account of Bithynia, Caria, Paphlagonia, Syria, Libya, Creta, and other countries. Clemens Alexandrinus quotes his treatise on the Jews, of which Eusebius has inserted fragments in his 'Chronography.' Clemens Alexandrinus mentions another work of Polyhistor, on the 'Symbol of Pythagoras;' and Cyril of Alexandria, in his work against Julian, quotes his authority on the early history of the world. Unfortunately none of Polyhistor's works have come down to us.

Polyhistor is also the title of a work on geography by Solinus. [SOLINUS.]

POLY'LEPAS, M. de Blainville's name for the genus *Scalpellum* of authors. [CIRRIPEDA, vol. vii., p. 208.]

POLYMIGNITE, *Titaniate of Iron, Zircon*, &c. Occurs crystallized. Primary form a right rhombic prism. Fracture conchoidal. Hardness, scratches phosphate of lime, and is scratched by felspar. Colour black. Lustre nearly metallic. Opaque. Specific gravity 4·806.

Before the blow-pipe, infusible; acted upon by sulphuric acid, when reduced to fine powder.

It is found in imbedded crystals at Frederiksvärn in Norway.

Analysis by Berzelius:—

Titanic acid	49·3
Oxide of iron	12·2
Oxide of cerium	5·0
Oxide of manganese	2·7
Zirconia	14·4
Yttria	11·5
Lime	4·2
Magnesia, potash, silica, and oxide of tin	traces
	99·3

POLYMORPHI'NA. [FORAMINIFERA, vol. x., p. 348.]

POLYNE'MUS, a genus of fishes, placed by Cuvier in his third division of the Percidæ, the species of which are distinguished by the ventral fins being inserted farther back than the pectorals. These fishes are further distinguished by having several long filaments beneath the pectoral fin; these are, in fact, free rays of that fin: their teeth are minute and dense as the pile on velvet, or recurved like the teeth in a carding-machine; they are found on both jaws, as well as on the vomer and palate. The general form of the body of the *Polynemi* somewhat resembles that of the perch; the muzzle projects over the mouth; the eyes are rather large and placed very forward; the dorsal fins are short and widely separated, and the caudal fin is large, and more or less forked. The scales extend on the fins, as in many of the *Sciænidæ*, which these fishes appear to approach in some other characters.

Considerable interest is attached to the *Polynemi* on account of some recent discoveries, which tend to show that they produce isinglass in considerable abundance.

The attention of the members of the Zoological Society was first directed to this subject by Dr. Cantor.[*] 'In the December number (1838) of Parbury's "Oriental Herald,"' says this naturalist, 'appears a letter "on the Suleah fish of Bengal, and the isinglass it affords:"' this fish, says the anonymous writer, when at its full size, attains about four feet in length, and is squaliform, resembling the shark species in appearance, but exhibiting a more delicate structure. The meat of this fish is exceedingly coarse, and is converted by the natives, when salted and spiced, into 'burtah,' a piquant relish, well known at the breakfast-tables of Bengal. The bladder of the *Suleah* may be considered the most valuable part of it; this, when exposed to the sun and suffered to dry, becomes purely pellucid, and so hard, that it will repel the edge of a sharp knife when applied to it. These bladders vary from half a pound to three-quarters of a pound avoirdupois in weight when perfectly dry. This fish abounds in Channel Creek, off Saugor, and in the ostia, or mouths, of all the rivers which intersect the Sunderbuns, and are exceedingly plentiful in certain seasons.

The discovery of isinglass as a product of India was so important, that Dr. Cantor determined to investigate the subject, and to ascertain, if possible, what the Suleah might be; when, quite unexpectedly, he received a letter from Mr. McClelland, in which that naturalist stated that he had examined this fish, and found it to be the *Polynemus Sele* of Hamilton's 'Fishes of the Ganges:' he moreover discovered that an individual of that species weighing two pounds would yield sixty-five grains of pure isinglass, an article which in India sells at sixteen rupees (1*l.* 12*s.*) per pound.

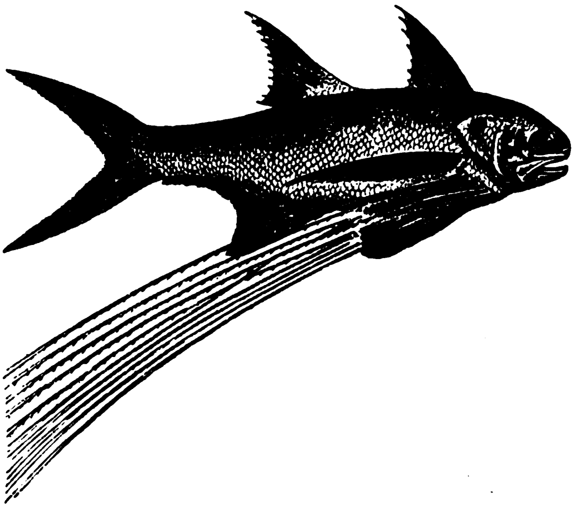
Thinking it highly probable that other species of *Polynemus* besides the *P. Sele* will yield isinglass, Dr. Cantor proceeds to give a short account of those species which came under his observation while attached as surgeon to the Honourable Company's Survey of the sea-face of the Gangetic delta.

'The species best known,' says the author, 'is the *Polynemus Risua* of Hamilton (*Pol. longifilis*, Cuvier; the Tupsee, or Mango Fish, of the Anglo-Indians): this inhabits the Bay of Bengal and the æstuaries of the Ganges, but enters the mouths of the rivers even higher up than Calcutta during the breeding season (April and May), when the fish is considered in its highest perfection, and is generally sought as a great delicacy. This species is the smallest, for its length seldom exceeds eight or nine inches, and one and a half or two inches in depth.' It is remarkable for the great length of filaments, or free rays, of the pectoral fins, these being about twice the length of the body, and seven in number on each side. *Polynemus aureus* and *P. Topsui* of Hamilton, Dr. Cantor states, are closely allied to this species. '*Polynemus Sele*, Hamilton (*P. plebeius*, Broussonnais; *P. lineatus*, Lacépède), is the Suleah fish mentioned in Parbury's "Oriental Herald," the same which Mr. McClelland submitted to examination. This species, as well as another closely allied to *P. quadrifilis*,[*] Cuvier, which I have dissected, figured, and described, under the name of *P. Salliah* (Saccolih), appears to be equally plentiful, in shoals, all the year round, in the æstuaries of the Ganges, and is appreciated by Europeans for its excellent flavour: both species attain a size from three to four feet in length, and eight to ten inches in depth.'

---

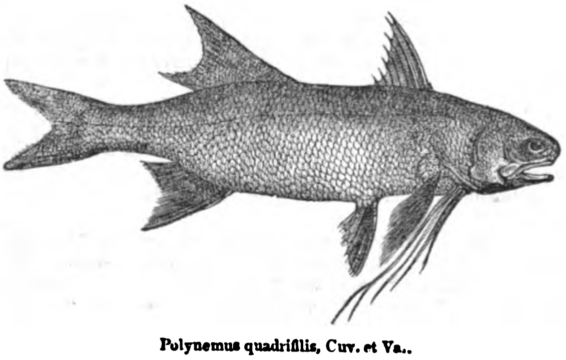
[*] See the 'Proceedings of the Zoological Society' for July, 1839.

Besides these species found on the coast of the mainland, two other species of Polynemus, *P. hexanemus* and *P. heptadactylus*, have been discovered off the coast of Java. On the coast of Africa and in the West Indies, certain species of the present genus are found. One of the African species is confounded by Cuvier with the Indian *P. longifilis*, and the mistake has been rectified by Mr. Bennett.[†] It appears that this species (which is in all probability the *Pentamenus* of Artedi, on which Linnæus established his *Pol. quinquarius*) differs from the Mango-fish of India in the number of free rays to the pectoral fins, the latter having seven rays, and the African species only five. MM. Cuvier and Valenciennes, not having found any species of *Polynemus* with so few as five free rays, and those longer than the body, imagined that the *Pol. quinquarius* was founded on a mutilated specimen. Several individuals[‡] however having this character being discovered by Captain Belcher, R.N., during his survey of a part of the Atlantic coast of North Africa, Mr. Bennett proposed to name the species after Artedi



Polynemus Artedii.

The second African species belongs to that section in which the free rays of the pectoral fins are short, and has received the name of *Polynemus quadrifilis*.



Polynemus quadrifilis, Cuv. et Va..

In the American Polynemus (*P. Americanus*) there are seven free rays to the pectoral fin, and these scarcely reach the tip of the ventral fins: it is about one foot in length, of a silvery colour; the pectoral fins are almost black, and the other fins are spotted with black.

POLYNE'SIA, a word formed from the Greek, and signifying 'many islands,' is a term which has not long been used in geography. When the numerous groups of islands dispersed over the Pacific, and the whole extent of what now is called Australia, became known, geographers felt the necessity of separating both from Asia, and of giving them a distinct description, and accordingly they sought for an appropriate name. The English geographers adopted that of Australasia, the German Australia, and the French Polynesia. Under this name the French geographers comprehended not only the several groups of islands which occur in the Pacific and the continent of Australia, but added to them all the islands east of the Bay of Bengal, or those which are commonly called the Indian Archipelago. But as those islands had always been considered an appurtenance of Asia, the name of Polynesia, in this extent of its signification, was not approved of, and it fell into disuse; and as it was not thought convenient to unite the great island of Australia with the other groups of the Pacific, the name of Polynesia has in modern times been restricted to those islands of the great ocean which are to the east of the Philippines, Moluccas, and Australia, and extend to the western coast of America. A few groups however, which are situated not far from the American continent, and therefore are considered as belonging to that continent, as Juan Fernandez, the Galapagos, and the Revillagigedo Islands, as well as the islands constituting the empire of Japan, the island of Formosa, and the Kurules, are excluded from this term. We shall merely enumerate the large islands and the groups of smaller islands comprehended under the name of Polynesia, as a more particular notice of them is given under their separate heads. South of the equator are Papua, the Admiralty Islands, New Ireland, with New Hanover, New Britain, Louisiade, New Georgia Archipelago, Queen Charlotte Islands, New Hebrides, New Caledonia, Vitis Islands, Friendly Islands, Navigator's Islands, Society Islands, Marquesas Islands, Pamuto Islands, and the isolated Easter Island; to which are to be added, south of the southern tropic, Pitcairn's Island, Norfolk Island, and the islands of New Zealand. North of the equator are the Pelew Islands, the New Philippines, the Ladrones, the Ralick, the Radack, and the Sandwich Islands.

POLYNOMIAL, an algebraical word meaning an expression which has several terms, being the general term under which are included, binomials, trinomials, quadrinomials, &c., or expressions of two, three, four, &c. terms. The *polynomial theorem* means the theorem by which a polynomial expression is raised to its several powers. For an easy way of doing this, see *Library of Useful Knowledge*, 'Diff. Calc.,' pp. 328-337.

POLYODONTA ('many-toothed tribe'), a name applied by Lamarck and M. de Blainville to the *Arcacea* of the former, the *Ark-shells*, &c. of collectors, comprehending the forms collected by Linnæus, in his 'Systema Naturæ,' under the genus *Arca*, and those designated by more modern zoologists as the genera *Arca*, *Cucullæa*, *Pectunculus*, and *Nucula*.

Lamarck's *Arcacea* constitute a part of his *Conchifères Ténuipèdes*, and are arranged by him between the *Cardiacées* and the *Trigonées*.

De Blainville places his family *Polyodonta* or *Arcacés* between the *Mytilacea* and *Submytilacea*.

Lamarck thus defines the family:—

'Cardinal teeth small, numerous, entering, and disposed in each valve in either a straight, a curved, or a broken line.'

M. Deshayes remarks, in the last edition of Lamarck, that the greater number of conchologists consider the family to be very natural, and not requiring any alteration, the relationship between the genera being apparent, and especially between *Cucullæa*, *Arca*, and *Pectunculus*; whilst the differences existing between them are of so little importance that their union under one natural genus may be well adopted. *Nucula* indeed does not appear to M. Deshayes to be so well connected with the preceding genera; for the *Nuculæ* are nacreous, a condition not observed in the others. The hinge teeth too of the *Nuculæ* have a different form, and they are in general more projecting than those of the *Arcæ* and *Pectunculi*; the position of their ligament distinguishes them still further. In the three preceding genera the ligament is external, and rolled up, as it were, behind the hinge; in the *Nuculæ* it is internal, and received into a small spoon-shaped cavity placed in the angle formed by the cardinal hinge. It is true, says M. Deshayes, in continuation, that among the *Nuculæ* are comprehended many species in which the ligament is external as in the *Pectunculi;* and these species are not nacreous. M. Deshayes suggests that it may be convenient to withdraw these species from the genus *Nucula*, to place them among the *Arcæ* and the *Pectunculi*, and thus separate them from the family of the *Arcadæ*, which family would be then well characterised by the position of the ligament and the nature of the hinge. He further, with reference to the figure published by M. Quoy, in the 'Voyage of the Astrolabe,' of the animal of a *Nucula* placed beneath that of a *Trigonia*, acknowledges that there is no denying that more analogy exists between them than had been at first supposed; but he also says that it is necessary to remark that the animal of the *Nucula* represented belongs to a species which has an external ligament, and which by that very organization approaches the *Trigoniæ* more than the others.

---

[*] The author most probably means the *P. tetradactylus*, which is an Indian species; the P. quadrifilis being an African species.

[†] See 'Proceedings of the Zoological Society' for 1830-31, p. 146.

[‡] The specimens referred to are in the museum of the Zoological Society.

M. Rang makes the *Arcadæ* consist of the genera *Cucullæa*, *Arca*, *Pectunculus*, *Nucula*, and *Trigonia*, and gives the following as the character of the family:—

Animal having the mantle entirely open throughout its circumference, excepting towards the back, without tubes or any particular apertures, and partially adherent; sometimes prolonged backwards; the foot always very considerable.

Shell generally thick, regular, equivalve, inequilateral, with a similar hinge in each valve always formed of serial teeth, which are often lamellar, fitting into each other, straight or oblique; muscular impressions nearly always united by a pallial impression, which is very narrow, and parallel to the border of the shell.

In this article we shall confine ourselves to the genera *Cucullæa*, *Arca*, *Pectunculus*, and *Nucula*. *Trigonia* will be treated of under TRIGONIA.

Cucullæa. (Lam.)

Generic Character.—*Animal* very thick, having the mantle a little prolonged backwards, and bordered by an irregular row of tentacular filaments; labial appendages small and triangular; foot large, pedunculated, compressed, and slit longitudinally.

Shell thick, navicular, equivalve, inequilateral, ventricose, with distant umbones; hinge linear, straight, formed of small transverse teeth for the greatest part of its length, and of many other teeth or longitudinal ribs; ligament entirely external; anterior muscular impression forming a projection with an angular or auriculate border. (Rang.)

M. Deshayes remarks that the *Cucullææ* differ but little from the *Arcæ*, and although they have a particular form, there are some species of the latter genus which establish the passage between the two genera. He observes that what most essentially distinguishes the *Cucullææ* from the *Arcæ*, are the transverse ribs placed at the extremities of the hinge, which ribs articulate together like the teeth of the *Arcæ*. All the *Arcæ*, he adds, have not the cardinal teeth upon a straight line; for this line in some species is curved at the extremities, and then the teeth become oblique, and in some species transverse: such species are closely approximated to *Cucullæa* in the hinge. Upon these grounds M. Deshayes is of opinion that the *Cucullææ* should be reunited to the *Arcæ* as a subdivision of the latter.

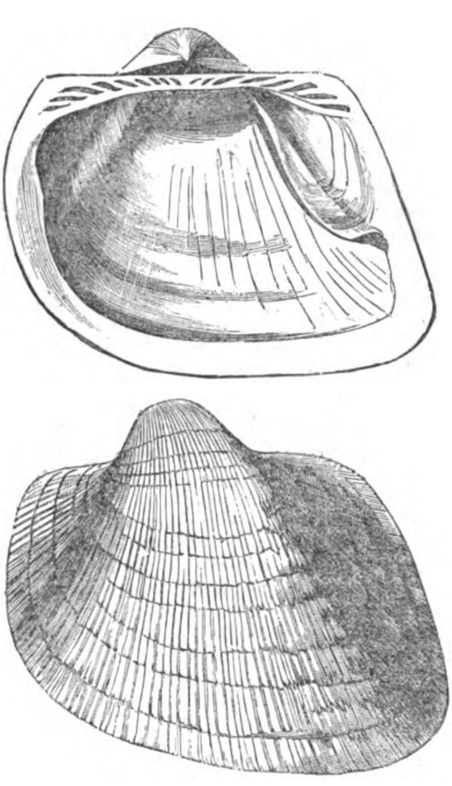
M. de Blainville had previously come to the same conclusion, for, in his 'Manuel de Malacologie,' he had, as will be seen more in detail when we come to treat of *Arca* properly so-called, made *Cucullæa* one of the subdivisions of that genus.

The number of recent species of *Cucullæa* recorded by M. Deshayes in his tables is one only; nor are any more noticed in the last edition of Lamarck.

This species is the *Arca concamerata* of Martini, *Arca Cucullus* of Gmelin, *Arca cucullata* of Chemnitz, and *Cucullæa auriculifera* of Lamarck, under which last name it is generally known; but, as M. Deshayes well remarks, Martini's name has the priority, and it ought to be that by which the species should be designated.

Description.—The shape of the shell, which is of fair size, will be seen better from the subjoined cut than from verbal description. The longitudinal striæ are more marked than the transverse striæ. The colour is rather a deep cinnamon-brown externally, and internally on the anterior part brown tinged with violet.

Locality.—The Indian Ocean; sandy bottoms.



Cucullæa auriculifera.

Arca. (Linn.)

Animal more or less thick, generally rather elongated; mantle prolonging itself slightly backwards, and with a row of tentacular filaments on its borders; labial appendages very small and slender; foot pedunculated, compressed, and slit throughout its length.

Shell navicular, rather thick, equivalve, inequilateral, elongated, more or less oblique; umbones distant and often a little recurved forwards; hinge linear, straight, furnished throughout its length with a numerous row of small teeth or transverse laminæ, which are equal and intrant; ligament entirely external.

M. Rang, who gives the above as the characters of *Arca*, remarks that the species sometimes adhere by their foot, and more frequently by means of a byssus.

M. Deshayes, in the last edition of Lamarck, observes that the organization of this genus has been well known since the publication of the great work of Poli, 'Testacea utriusque Siciliæ,' where he has demonstrated the anatomy of *Arca Noæ;* and that it were to be wished that the anatomy of a species which is perfectly closed, *Arca antiquata*, for example, should be detailed in the same manner. The external form of the animal approximates much to that of the shell itself; the lobes of the mantle are disunited throughout its length; they are delicate, and leave towards their median part a small gap corresponding to that of the shell: the body is rather thick. From the median part of the abdominal mass is elevated a very short thick truncated foot, offering at its truncation an oval and rather considerable mass of horny compact matter, in lieu of the silky byssus of some other *Conchifera*, and which serves both for attachment and also as a sort of *operculum* to close the gaping of the valves into which it passes. On each side of the body may be seen, nearly throughout the length of the animal, two branchiæ, which are nearly equal, and composed of very fine and very flexible detached filaments. At the anterior part of the foot and of the abdominal mass there is a transverse slit of a moderate extent, having on each side two slightly projecting lips, but which are prolonged to the lateral parts of the body: this slit is the buccal aperture, and the lips are the labial palps. There are two adductor muscles which attach the animal to the shell; they are distant and situated at each extremity, the posterior being the most considerable. The animal is provided with powerful muscles proper to the foot, and these last leave on the internal and superior surface a particular impression much larger than is seen in the greater number of the other animals of this class. The buccal aperture leads into a narrow and rather long œsophagus, at the side of which and opening at its lower part is a small elongated pouch, in which is contained a small horny stylet. The œsophagus terminates at a very small globular stomach, in the walls of which are seen large crypts, by which the liver, which envelopes it, pours in its secretion. The intestine is slender, and makes only a single circuit, so as to reach the dorsal and median line, passes behind the posterior retractor muscle, and terminates by an anus turned downwards. The organs of circulation have a particular disposition in the *Arcæ*, very different from what is known in the other *acephalous mollusca*. In nearly all the mollusks of this class the heart has a single ventricle embracing the rectum, and placed in the dorsal and median line of the animal. In the Arks, the back of the animal being very wide and the branchiæ very distant at their insertion upon the lateral parts of the body, there is a ventricle and an auricle for each pair of branchiæ, or, in other words, there are in this genus two hearts. The nervous system is very considerable: the principal branches of it are to be seen on the internal surface of the posterior retractor muscle.

M. Deshayes adds, that if this organization be compared with that of the *Pectunculi*, sufficient differences will be found to justify the separation of the two genera; but he appears to think that this might not be the case if the animal of those *Arcæ* which have no byssus were known.

M. de Blainville divides the *Arcæ* into the following subdivisions:—

A. (*Les Navicules.*)

Navicular species; the hinge completely straight; the foot tendinous and adherent. (*Byssoarca*, Sw.) [Byssoarca.]

Example, *Arca Noæ*.

B. (*Les Bistournées*—Genus *Trisis*, Oken.)

Example, *Arca tortuosa*.

C. (Genus *Cucullæa*, Lam.)

Navicular species; the hinge completely straight; the terminal teeth much longer and more oblique than the others.

Example, *Cucullæa auriculifera*, Lam.

D.

Species with a straight hinge not notched or not gaping inferiorly.

Example, *Arca barbata*.

E. (Les Rhomboides.)

Species well closed, of less elongated form, more pectinoid, and with a straight hinge.

Example, *Arca rhombea*.

F.

Oval species, elongated or a little arched longitudinally, slightly gaping inferiorly, with the umbones at little distance from each other, the ligament nearly internal, and the dental line a little bent.

Example, *Arca mytiloïdea*.

The number of recent species recorded by M. Deshayes, in his Tables, is forty-three, and of these *Arcæ semitorta*, *Noæ*, *tetragona*, *umbonata*, *barbata*, *Magellanica*, *Helbingii*, *antiquata*, *rhombea*, *clathrata*, a new species, *Gaymardii*, and *Quoyi*, are noted as both living and fossil (tertiary). In the last edition of Lamarck forty is the number given. Both these numbers are however below the mark. For instance, no notice is taken in Lamarck of the fifteen new species collected by Mr. Cuming, and described by Mr. G. B. Sowerby. (*Zool. Proc.*, 1833.)

The following descriptions and cuts will give some idea of the difference of form assumed by the shells of this genus:—

Arca Noæ.

Description.—Shell oblong, striated; apex emarginate; umbones very remote, incurved; margin gaping.

Locality.—Atlantic Ocean, seas of Europe.

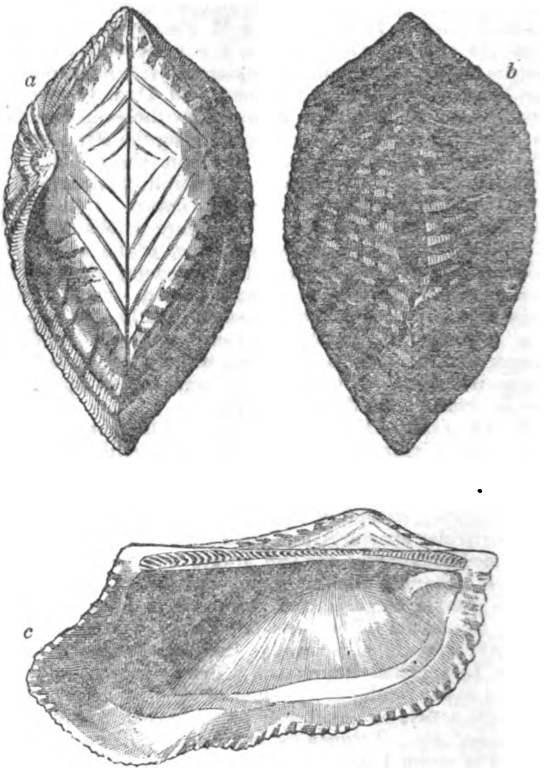
Arca tortuosa—(Genus *Trisis*, Oken).

Description.—Shell twisted, parallelipiped, striated; valves obliquely carinated; umbones small, recurved.

Locality.—The Indian Ocean.

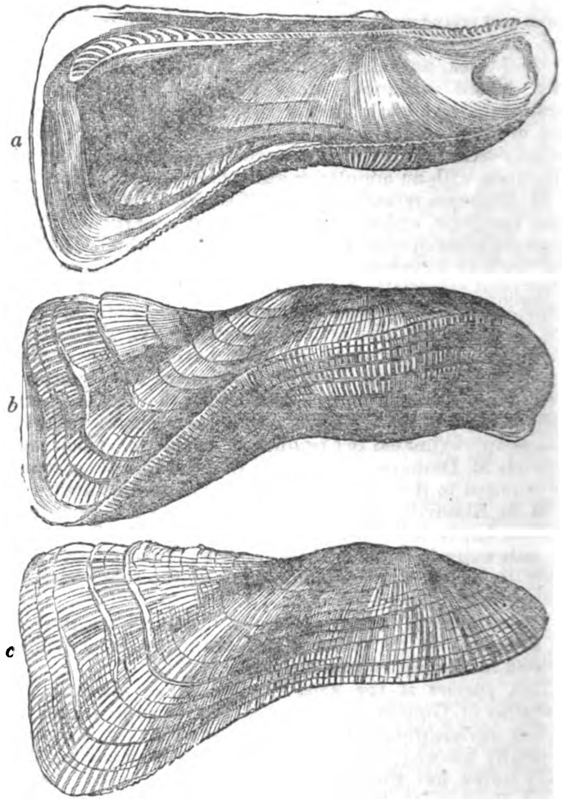
Arca antiquata.

Description.—Shell transverse, obliquely cordate, ventricose, many-ribbed; the ribs transversely striated and blunt; the posterior ribs bifid. Colour white.



Arca Noæ.

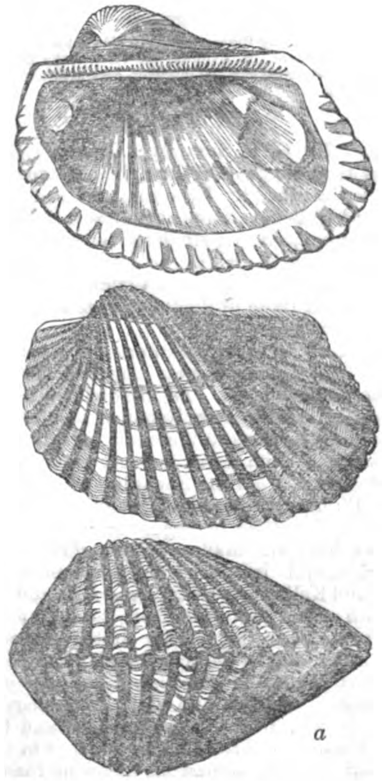
a, valves closed, with the umbones and area of the hinge towards the spectator; *b*, valves closed, with the ventral or inferior aspect, showing the margin, opposite to the spectator; *c*, internal view of one of the valves.



Arca tortuosa.

a, internal view of a valve; *b*, valves closed, the ventral or inferior margin towards the spectator; *c*, external view of a valve.

Locality.—Lamarck gives the Indian Ocean, the coasts of Africa, and the Mediterranean as the localities of this species, of which M. Deshayes, in the last edition of the *Animaux sans Vertèbres*, says that he is convinced that since the time of Linnæus two species at least have been confounded under the denomination of *Arca antiquata*, although they are easily distinguished; the one, more transverse, has the cardinal surface always furrowed into lozenge shapes when the valves are united; the other having a thicker shell, the ribs flatter, wider, and striated, but never with furrows on the cardinal surface. This last, being the most common and most antiently known, should, in his opinion, retain the name of *Arca antiquata*, and he cites the following figures of the shell:—*Gualt. Test.*, pl. 87, f. C; Chemn., *Conch.*, t. vii., pl. 55, f. 548; *Encyclop.*, pl. 306, f. 2; Gronov., *Zooph.*, pl. 18, f. 13. M. Deshayes further remarks, that the shell figured by Poli and cited by Lamarck in the synonymy constitutes a species distinct from the two others. He adds that this, which inhabits the Mediterranean, is the living analogue of *Arca diluvii*. Neither, in his opinion, is the *Arca antiquata* of Brocchi a true *antiquata*, but the *Arca diluvii*, the fossil analogue of the species figured by Poli.



Arca antiquata.

a, valves closed, inferior or ventral margin towards the spectator.

Habits of the Genus.—The *Arcæ* have hitherto been found on bottoms of sandy mud and mud, at depths varying from the surface to seventeen fathoms. Some of the species are moored to stones, corals, &c.

Pectunculus, Lam.

Generic Character.—Animal rounded, more or less thick, with no tentacular filaments on the border of its mantle; labial appendages very narrow; foot large, compressed, and slit longitudinally.

Shell lenticular, thick, solid, equivalve, subequilateral, entirely closed; umbones rather small and more or less distant; hinge formed of a curvilinear row of small narrow, rather numerous, intrant teeth, which are often incomplete under the umbones; ligament external. (Rang.)

Habits of the Genus.—The Pectunculi live on sandy or muddy bottoms, and have been found at depths ranging from five to seventeen fathoms. They move by means of the foot, which the animal uses to propel itself.

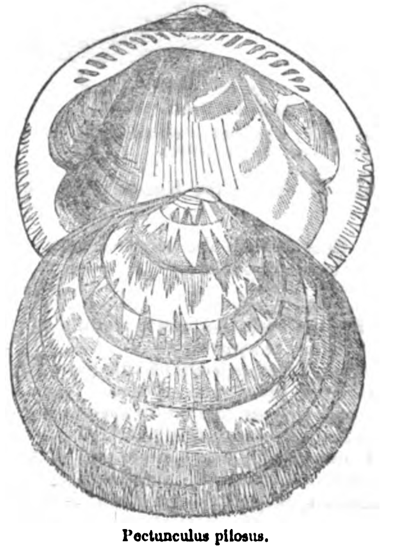
M. Deshayes observes, in the last edition of Lamarck, that if, in some important points, the organization of the *Pectunculi* differs from that of the *Arcæ*, in others great analogy exists. The *Pectunculi*, having no byssus, live free, and have a foot formed nearly like the edge of an axe. When that organ is contracted, the edge seems simple; but when the animal dilates it, its lower part exhibits an oblong disk circumscribed by a sharp border: this disk bears much resemblance to that upon which the Gastropods creep. The branchiæ are formed of long filaments, as in the *Arcæ;* the abdominal mass is considerable, and the foot is attached throughout its length. The buccal aperture is between the anterior part of the abdominal mass and the anterior retractor muscle; it is in the shape of a transverse slit between the two lips, which are prolonged on each side of the muscle and ascend nearly to the base of the branchiæ. The œsophagus is long and narrow, and has no horny stylet; it terminates in a pyriform stomach, from which comes a slender, cylindrical, and very long intestine, which, after having made many circumvolutions, arrives at the median and dorsal part of the animal, passes behind the posterior adductor muscle, is contorted so as to follow its surface, and terminates towards its inferior border, where it ends in a floating anus. The heart is simple; a single ventricle embraces the rectum; the auricles are very large, and do not pour out the blood to the branchiæ by their border, but they terminate anteriorly by two vessels, which are curved backwards so as to furnish a small vessel to each of the branchial filaments.

The number of living species stated in the tables of M. Deshayes is nineteen, and of these the following are recorded as both living and fossil (tertiary):—*Pectunculi glycymeris*, *pilosus*, *violacescens*, and *nummarius*. The number given in the last edition of Lamarck is twenty; but the nine species named and described by Mr. Broderip and Mr. G. B. Sowerby respectively, from Mr. Cuming's collection (*Zool. Proc.*, 1822; Müller, *Synopsis*), are omitted.

Example, *Pectunculus pilosus*.

Description.—Shell orbiculate; ovate, tumid, marked with decussate striæ; umbones oblique; epidermis brown, hairy.

Localities.—The Mediterranean and the Atlantic Ocean. (Lam.)



Pectunculus pilosus.

Nucula, Lam.

Generic Character.—Animal rather thick, subtriquetrous, having the mantle open only in its inferior moiety, with entire borders, denticulated throughout the length of the back, without posterior prolongations; anterior buccal appendages rather long, pointed, stiff, applied one against the other, like a kind of jaws, the posterior ones equally stiff and vertical; foot very large, delicate at its root, enlarged into a great oval disk, the borders of which are furnished with tentacular digitations.

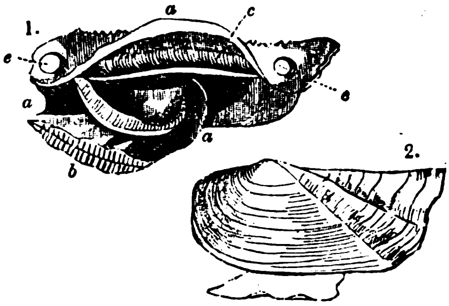
Shell rather thick, sometimes nacreous, subtriquetrous, equivalve, inequilateral; umbones contiguous and curved forwards; hinge formed on each valve of a numerous row of small pointed teeth, disposed in a line broken under the umbo; ligament in great part internal, short, and inserted in a small oblique fosset in each valve. (Rang.)

Habits of the Genus.—The species have been found on bottoms of sandy mud and sand, both in æstuaries and the open sea, at depths varying from the surface to sixty fathoms. According to Mr. Cuming, the same species vary much as to the depths at which they live; for he found

N. cuneata from fourteen to forty-five fathoms; *N. obliqua* from fourteen to sixty fathoms; and *N. Pisum* from seventeen to forty-five fathoms.

M. Deshayes, in the last edition of Lamarck, remarks, that though there is a species of *Nucula* widely spread in the British Channel and the Mediterranean, the animal remained unknown until M. Quoy figured that of a large and very curious species in the 'Voyage of the Astrolabe.' This animal, observes M. Deshayes, has, as Lamarck predicted, much analogy with that of the *Pectunculi* and *Arcæ*. The foot is compressed laterally, and slit at its free border, so that it can be dilated into a disk for creeping progression. The mantle-lobes are disunited throughout the length of their inferior border. The abdominal mass is not thick, and the foot is attached to it throughout its length; on each side and above are found the branchiæ, which are nearly as long as the entire animal, and very narrow. According to the figure, they seem to be composed of detached filaments, as in the *Arcæ* and *Pectunculi*.

In front of the abdominal mass, and near the anterior adductor muscle, is the mouth, on each side of which is a pair of palps, very narrow and very much elongated on each side of the visceral mass: these palps are foliaceous on their internal surface. The internal organization does not appear to be known; but M. Deshayes is of opinion that it may be predicated to bear much resemblance with that of the *Pectunculi*.



Animal of Nucula Australis.

1. *a a*, mantle; *b*, foot; *c*, branchia; *e e*, adductor muscles. 2. Outline of shell, with the foot of the animal projecting.

M. de Blainville divides the *Nuculæ* into two sections:—

A.

Species with the border entire.

Example, *Nucula rostrata.*

B.

Species with the border crenulated.

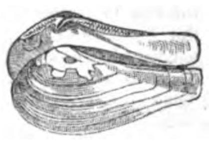
Example, *Nucula margaritacea.*

The number of recent species of this genus in the Tables of M. Deshayes is seven, and of these, *Nuculæ margaritacea, Pella, emarginata,* and a new species, are recorded as occurring both living and fossil (tertiary). In the last edition of Lamarck the number recorded is ten. M. Deshayes however, who seems to confound the authors of the 'Mineral Conchology' and the 'Genera,' considering them as identical, says that Mr. Sowerby has added some living species in his genera, but that it is to Mr. Cuming to whom we owe the knowledge of the greatest number. He then proceeds to state that the latter has described them in the 'Proceedings of the Zoological Society of London,' and caused them to be figured in the 'Conchological Illustrations' published by Mr. Sowerby, and that he has described thirty-four living species. Still he gives but four of the new species in the text, attributing the names and descriptions to Mr. Cuming, who certainly collected them, but did not describe one. The names and descriptions are by Mr. G. B. Sowerby, who described ten from Mr. Cuming's collection, in the 'Zoological Proceedings' for 1832 (see also Müller's 'Synopsis'), which, strangely enough, are quoted by M. Deshayes for the description of the four which he has admitted into the body of the new edition of the 'Animaux sans Vertèbres.'

The following descriptions and cuts will give some idea of the forms of this genus.

Example, *Nucula rostrata.*

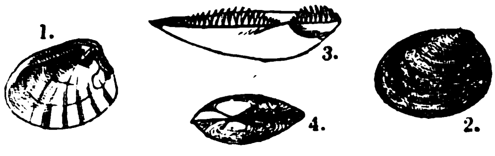
Description.—Shell transverse, oblong, rather, convex, thin, transversely striated; anterior side longest, attenuated and rostrated.



Nucula rostrata.

Example, *Nucula margaritacea.*

Description.—Shell obliquely ovate, trigonal, rather smooth; cardinal teeth straight, acute; margin crenulated.



Nucula margaritacea.

1. Interior of valve, showing the teeth on each side of the hinge and the cartilaginous pit in the centre. 2. Exterior. 3. View of the teeth, the dorsal margin of the shell being towards the observer, enlarged. 4. Valves closed, showing the umbones.

FOSSIL ARCADÆ.

Cucullæa. Mr. G. B. Sowerby ('Genera') notices the fossil species as numerous; of these, he observes, one (*Cuc. crassatina*) is described by Lamarck, and is found in the neighbourhood of Beauvais and at Bordeaux, in beds similar to that of Grignon, but in England several species occur, both in the greensand and in the inferior oolite, and are engraved in Sowerby's 'Mineral Conchology.' Mr. G. B. Sowerby adds, that those of the inferior oolite are also found at Bayeux in Normandy.

The number of fossil species (tertiary) recorded by M. Deshayes in his Tables is two. In the last edition of Lamarck the number is six. Dr. Mantell, in his 'Tabular Arrangement of the Organic Remains of the County of Sussex,' notes a *Cucullæa* in the chalk marl, and adds that M. Brongniart sent him a similar cast from Rouen; also *Cucullæa decussata*, from the Shanklin sand (Feversham).

Professor Phillips ('Organic Remains of the Yorkshire Coast') records *Cucullææ oblonga, contracta, triangularis,* and *pectinata*, from the coralline oolite; *elongata* from the coralline, Bath, and inferior oolite; *concinna* from the Oxford clay and Kelloway's rock; *imperialis* and *cylindrica* from the Bath oolite; *cancellata* from the Bath and inferior oolite; *reticulata* from the inferior oolite; and notices the occurrence of the form in the Speeton clay and the lias. In the second part (1836) he describes *Cucullææ obtusa* and *arguta* (Bolland). ('Illustrations of the Geology of Yorkshire.') Dr. Fitton, in his 'Stratigraphical and Local Distribution of Fossils,' in his valuable paper 'On the Strata below the Chalk' (1839), notices the following *Cucullææ*:—*carinata* (Blackdown); *costellata ?* (lower green-sand, Kent; Blackdown, Devon); *decussata* (upper green-sand, Isle of Wight; lower green-sand, Kent and Sussex; Blackdown); *fibrosa* (Blackdown, Devon); *formosa* (Blackdown); *glabra* (upper green-sand, Isle of Wight; lower green-sand, Kent; Blackdown, Devon); *glabra ?* (lower green-sand, Sussex); *doubtful* (upper green-sand, Hampshire; lower green-sand, Kent); *one or two* other species (lower green-sand, Sussex); *new* (lower green-sand, Kent; Oxford oolite, Cambridge); a *Cucullæa* without any designation (lower green-sand, North Wilts); and a *small species* from the Portland sand, Dorsetshire.

Mr. Lonsdale, in his elaborate paper 'On the Oolitic District of Bath,' mentions *Cucullæa oblonga* (inferior oolite, Widcombe Hill) and *Cucullæa glabra* (upper green-sand, neighbourhood of Warminster). Mr. Murchison ('Silurian System') describes and figures *Cucullæa antiqua* from the old red-sandstone (middle and lower beds only) and the upper Ludlow rock; *Cuc. Cawdori* from the upper Ludlow rock, with a ?; and *Cuc. ovata* from the old red-sandstone (middle and lower beds only). Professor Sedgwick and himself had previously given Gosau as a locality for *Cucullæa carinata.* ('Structure of the Eastern Alps.')

Arca. The number of fossil species (tertiary) given by M. Deshayes in his Tables is fifty-four, several of which, as we have seen above, he records as both living and fossil (tertiary). In the last edition of Lamarck no more than eighteen, fossil only, are catalogued. Dr. Mantell mentions two or three undetermined species from the chalk marl (Ringmer), and *Arca carinata* from the firestone or upper green-sand, Southbourn, Sussex, and Devizes); and another (a very imperfect cast) from the galt or Folkstone marl (Ringmer). Professor Phillips notes *Arcæ quadrisulcata* and *æmula* from the coralline oolite, Yorkshire; Mr. Lonsdale notes an *Arca* from the inferior oolite (canal banks opposite Limpley Stoke), and another from Frome; also one from the Bradford clay. Professor Sedgwick and Mr. Murchison record one from Gosau. Dr. Fitton gives *Arca carinata* from the upper green-sand, Hampshire; *A. rotundata* from Blackdown, and an uncertain species from the lower green-sand, North Wilts, the Portland stone, Oxford, and the Oxford oolite, Cambridge. Mr. Murchison ('Silurian System') describes and figures *Arca Eastnori* from the Wenlock shale.

Pectunculus. Mr. G. B. Sowerby ('Genera') states that all the species known to him are found either in the London clay or the calcaire grossier; he says that a very neat one occurs in the indurated marl at Bognor, where it is accompanied by fossil *Pinnæ, Linguli,* &c., and he has figured it, believing it to be a variety of Lamarck's *Pectunculus pulvinatus,* 'but in truth,' he adds, 'it is so difficult to fix the characters of the species of this genus, that we dare not speak decidedly upon this point.' M. Deshayes enumerates, in his Tables, twenty-seven fossil species (tertiary), and of these he notices three, as above mentioned, as both living and fossil (tertiary). In the last edition of Lamarck but fifteen species, fossil only, are catalogued. Dr. Mantell notes *Pectunculus pulvinatus* from the blue clay of Bracklesham; *P. brevirostris* and *P. decussatus*[*] from the arenaceous limestone or sandstone of Bognor. Professor Sedgwick and Mr. Murchison enumerate *Pectunculi Plumsteadiensis, brevirostris, pulvinatus?* and *calvus* from the Gosau deposits; and Mr. Lea describes and figures *Pectunculi Broderipii, minor, deltoideus, ellipsis,* and *obliqua* from the Claiborne beds (tertiary), Alabama.

Nucula. The number of fossil species (tertiary) published in the Tables of M. Deshayes is twenty-three, and four are enumerated as both living and fossil (tertiary). (See above.) In the last edition of Lamarck only seven are catalogued as fossil only. Dr. Mantell notices *Nucula pectinata* from the gault or Folkstone marl; and *Nuc. impressa* from Blackdown. Professor Phillips records *Nuculæ ovata* and *subrecurva* from the Speeton clay; *subrecurva* from the inferior oolite; another from the coralline oolite; *elliptica* and *nuda* from the Oxford clay; *variabilis* and *lachryma* from the Bath and inferior oolite; *axiniformis,* inferior oolite; *ovum* and *complanata,* upper lias; *cuneata, tumida, undulata, claviformis ?* and *Luciniformis* (Bolland, &c.), and *brevirostris,* Harelaw, Northumberland. (*Yorkshire.*) Mr. Lonsdale notes *Nucula pectinata* from the Bradford clay; and another from the forest marble. Professor Sedgwick and Mr. Murchison give us *Nuculæ amygdaloides* and *concinna* in their list of *Gosau Fossils.* Dr. Fitton enumerates *Nuculæ angulata* (Blackdown); *antiquata* (lower green-sand, Sussex, and Blackdown); *apiculata* (Blackdown); *bivirgata* (gault, Kent); *impressa* (lower green-sand, Sussex, and Blackdown); *lineata* (Blackdown); *obtusa* (Blackdown); *ovata* (gault and lower green-sand, Kent); *pectinata* (gault, Kent, Cambridge, South Wilts, Blackdown, Devon); *undulata ?* (gault, Kent), and another (gault, Bedford).

Mr. Murchison figures and describes *Nuculæ ? ovalis,* and *lævis*; the first from the upper Ludlow rock, the second from the Llandeilo flags. ('Sil. Syst.') Mr. Lea describes and figures *Nuculæ Sedgwickii, ovula, pectuncularis, Brongniarti, media, pulcherrima, plicata, magna, carinifera, plana,* and *semen,* from the Claiborne beds.

POLYPE. The discoveries of Trembley regarding the structure and animal functions of the phytoïd Hydræ, and Plumatellæ of fresh water, opened a new field of research into the nature and relations of many neglected forms of life, and gave occasion for much correct inference and baseless conjecture. Borrowing from Aristotle and Pliny the term Polypus, by them applied to a cephalopod, the systematic naturalists who followed Linnæus collected under this title many really animalised masses in the form of plants, and after abundant examinations by Ellis and others of the membranous, horny, or stony 'fulcra,' bases, or axes, which remain after desiccation or decay of the softer parts, generally agreed in opinion that to all these plant-like bodies were associated active living animals like the Hydræ described by Trembley.

As in a tree the flowering and reproductive organs manifest more active and varied functions than the general mass of bark and wood which serves to unite them in one common life, so in these Zoophyta the little Polypi expanding from their cells for food, light, or aëration, and shrinking back upon the agitation of the water, or withdrawal of the light, seemed like so many animal flowers, which might be studied apart from the Polypiaria which they adorned. They were in fact studied apart, and unfortunately attention was more directed to the wonderful permanent fabric, or 'Polypidom,' as Lamouroux calls it, than to the Polypi themselves. Hence the imperfection of all the schemes of classification for this portion of the Zoophytic division of the animal kingdom, and many of the erroneous generalizations and hypotheses regarding the lower forms of animal life. There was besides a real impediment in the way of accurate and satisfactory observation of these minute parts of creation in the imperfection of microscopes. Until Amici, Chevalier, Prichard, Plösl, gave us powerful reflecting and achromatic engines, it was vain to look for stomachs in the Polygastrica and a variety of internal organization in the supposed simple Polypi of the so-called 'sea-weed.'

One of the most interesting disquisitions on the Polypean races—that of Lamarck ('Anim. sans Vertèb.,' tom. i.)—fixed for these animals the characters of gelatinous contractile body; alimentary canal with a single opening surrounded by ciliæ or tentacula; reproduction by gemmæ, internal or external; organs of sense, respiration, or fecundation none; often associated into compound existence. If to these definitions we add the notion of extraordinary tenacity of life, manifested by the survival and multiplication of Hydræ under the knife, the surprising fact ascertained in the Hydra by Trembley of the external surface taking up the function of digestion when the animal was turned inside out, the varieties of gemmiparism observed in Sertularia, Cellaria, &c., by Ellis and others, and the employment of the tentacula or ciliæ around the mouth,—we shall see the state of this branch of zoology in the time of Lamarck.

That distinguished systematist presented a very simple and popular classification of Polypes, namely:—

Polypi ciliati, as many of the Rotiferous Infusoria.
Polypi denudati, as the Hydra.
Polypi vaginati, as the compound Sertulariæ, Corals, &c.
Polypi tubiferi, as the Lobularia and its allies.
Polypi natantes, as the Pennatulariæ.

The Actiniæ, thus expressly excluded from the class of Polypi, are very closely related to them. They are accordingly placed with them by Dr. Johnston, in his easy and effective system, thus:—

Subclass 1. Radiated Zoophyta

Body contractile in every part, symmetrical; alimentary canal with one opening; gemmiparous and oviparous.

Order 1. Hydroida. Polypes compound; mouth with filiform simple tentacula; stomach excavated in the cellular substance of the body; no distinct muscular apparatus, the body contractile in all its parts; gemmiparous externally; polypidom (if existing) external to the polypes. (Hydra, Sertularia, &c. Nudibrachiata of Farre.)

Order 2. Asteroida. Polypes compound; mouth encircled with 8 fringed tentacula; gemmiparous internally; stomach membranous; polypidom an internal axis. (Gorgonia, &c.)

Order 3. Helianthoïda. Polypes single; mouth encircled by tubulous (aquiferous?) tentacula; stomach membranous, plaited; oviparous by internal ovaria. (Actinia, &c.)

Subclass 2. Molluscar Zoophyta. (Ciliobrachiata of Farre. Bryozoa of Ehrenberg.) Body not contractile, symmetrical; mouth and anus separate; gemmiparous and oviparous.

Order 4. Ascidioida. Polypes aggregated; the mouth encircled with filiform ciliated tentacula; stomach distinct, intestine recurved to an anus near the mouth; ova internal. (Cellaria, &c.)

Thus we find among the Cellaria, Flustra, &c., which Lamarck ranked in his Polypi, animals quite different from his type, and making very near approach to the higher group of Tunicate Mollusca. On the other hand, Sponges, which Lamarck admitted, are excluded by Johnston and many modern writers, and constitute, in Dr. Grant's view, the class of Porifera. Whether they be of vegetable or animal origin, they certainly have no polypi. Dr. Farre (*Phil. Trans.* for 1837), who has paid successful attention to some of the higher groups of Polypi, and who unites in one group, Anthozoa, the second and third orders of Dr. Johnston, says, 'it appears that under the commonly received name of Polypi there exist three distinct types of structure, which must be referred to the same number of separate classes, possessing but few points in common, and these generally of the most superficial kind.' [POLYPIARIA; ZOOPHYTARIA.]

---

[*] Dr. Mantell observes that, as it differs from the recent *P decussatus,* different specific name should be found for it.

POLYPHE'MUS (Conchology), De Montfort's name for a genus consisting of those species of *Achatina* which have elongated apertures, short spires, and an undulation in the outer lip.

Example, *Polyphemus Glans.*

Polyphemus is also a name given by Müller and others to certain crustaceans belonging to the order *Lophyropa*, Latr.

POLYPHY'LLIA. [MADREPHYLLIŒA.]

POLYPHY'SA, the genus formed by Lamouroux for a marine plant-like body allied to Corallina. [PSEUDOZOARIA.]

POLYPIA'RIA. In subdividing the Linnæan Zoophyta, naturalists have generally recognised the propriety of separating in one distinct class the compound, plant-like, generally polypiferous animals; Lamarck, Lamouroux, and Cuvier agree in this. Blainville's system of classification employs the term Polypiaria for one of several related classes (procured by dismemberment of Lamarck's Polypi), and divides it into four important subclasses, viz. Polypiaria solida, Polypiaria membranacea, Polypiaria dubia, Polypiaria nuda. In the present article we shall present a condensed view of the three latter classes, referring for the two families of the first to their respective titles, MILLEPORIDÆ and TUBULIPORIDÆ; and for some general views of the classification of Polypian animals to POLYPE and ZOOPHYTARIA.

The active animal parts of the Polypiaria of Blainville are generally of slender figure, provided with filiform tentacula in one row, and either nude or contained in cells of various form and substance, but never lamelliferous, agglomerated together.

The subclasses are thus defined:

Polypiaria solida. Animals contained in small calcareous cells, with a terminal opening, accumulated into a solid fixed polyparium. Ovaria internal?

Fam. 1. Milleporidæ.
Fam. 2. Tubuliporidæ.

Polypiaria membranacea. Animals very short, urceolated, provided with many tentacula (often ciliated) in one row, contained in membranous, rarely calcareous, adherent cells, with a more or less bilateral opening. Ovaries external.

Fam. 1. P. operculifera.
Fam. 2. P. cellariæa.
Fam. 3. P. sertulariæa.

Polypiaria dubia. Animals urceiform, provided with long (often ciliated) tentacula, arranged in a curvilinear form above and around the opening of the mouth, and springing from a common membranous basis. (*Zoophyta ascidioïda;* Fam. *Limniadæ*, Johnston.)

Polypiaria nuda. Body gelatinous, very contractile, free, excavated into a gastric cavity, of simple form, provided at its entrance with cirrhose tentacula; no trace of viscera; reproduction by external germs. (Part of Zoophyta hydroïda of Dr. Johnston.)

POLYPIARIA MEMBRANACEA.

Fam. 1. *Operculifera* or *Eschariæa.*

Animals provided with a horny operculum for closing the cells which contain them. Intestinal canal with two openings. (Dr. Johnston includes them in his order of Zoophyta ascidioïda. Milne Edwards calls them Bryozoaria. They belong to Dr. Farre's Ciliobrachiata.)

Genera.

Myriapora.

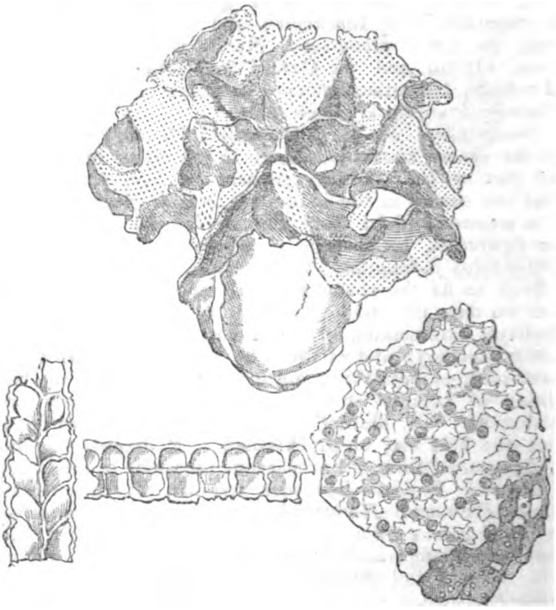
Animals cylindrical, terminating anteriorly in a tubular extensible proboscis, surrounded by many simple tentacula arranged into the shape of a funnel; on one side of this body is a cartilaginous round operculum. Cells simple, oval, with a small round opening, united into a calcareous, fixed, ramified, finely porous polyparium.

Example, Millepora truncata, Linn. (recent). Sol. and Ellis, tab. 23, f. 1-8.

Eschara.

Animals swollen in the cephalic region, and bearing a circle of simple filiform ciliæ. Cells not prominent, indistinct externally, having a depressed small round operculated orifice, uniting regularly in quincunx, so as to constitute a calcareous, brittle, friable, porous, leaf-like polyparium of variable shape.

Example, Eschara foliacea. Ellis's 'Corallines,' t. 30, f. *a*, *b*, *c*.



Eschara foliacea.

Blainville includes in this genus several Celleporæ of Linnæus, Goldfuss, and Fleming. Mr. Lonsdale gives a fossil species from the Silurian rocks, and Goldfuss names no less than twelve from the chalk and tertiary strata.

Milne Edwards has proposed to divide the genus into three, according to the structure of the cells (*Ann. des Sci. Nat.*, 2nd series, tom. vi.):—

Eschara, in which the adjoining cells are closely united, and the anterior part is semicorneous.

Membranipora, with a calcareous border and a membranous centre to the cell.

Escharina; cells juxtaposed, circumscribed, the extero-anterior parietes calcareous to the edge of the small operculated opening.

Of this genus Mr. Lonsdale gives a dubious species from the Wenlock rocks.

Ptilodictya (fossil), Lonsdale.

Thin elongated expansions, having on each surface small quadrangular cells not convex, which penetrate the coral obliquely, and are arranged, with respect to the surface, in longitudinal lines on the middle, and in oblique lines on the sides. Surface a thin calcareous crust. Opening of the cells small, transversely oval. No partition, as in Eschara, between the two layers of cells.

Example, Flustra lanceolata, Goldfuss. ('Pétref.,' tab. 37, f. 2.)

Diastophora (fossil), Lamouroux.

Animals unknown. Cells rather tubular, with rounded opening, disposed irregularly in vertical rows on one face of a lamelliform, irregular, variously expanded polyparium.

Example, Diastopora foliacea, Lamx. From the oolite of Caen.

Ocellaria (fossil), Ramond.

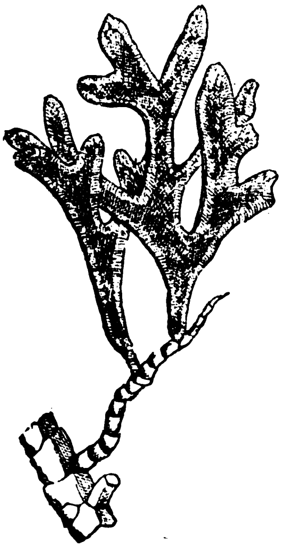
Animals unknown. Cells rounded, elevated in the middle, and united in quincunx on the two faces of a stony, frondescent, variously shaped polyparium.

Example, Ocellaria nuda. From the chalk of Mont Perdu.

Adeona, Lamouroux.

Animals unknown. Cells very small, indistinct externally, with a round, impressed, poriform, operculated opening, closely united quincuncially on the two faces of a foliaceous polyparium connected with an articulated stem.

Example, Adeona foliifera, Lamarck. Blainville, pl. 76, f. 2.



Adeona foliifera.

Mesenteripora, Blainville.

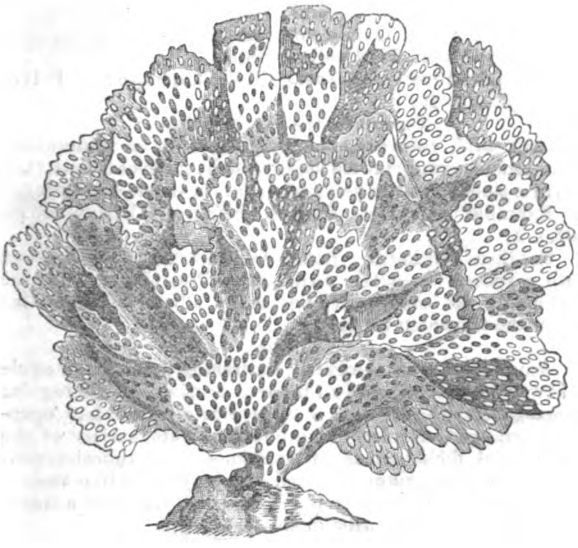
Animals unknown. Cells distinct, oval, oblique, rather prominent, with a subterminal oblique opening; ranged regularly in quincunx in two series, united so as to form a fixed calcareous polyparium, composed of convoluted expansions radiating from the point of attachment.

Example, Mesenteripora scobinula (Eschara of Lamarck). There are fossil species from the oolites of Caen and Bath.

Retepora.

Animals very small, slender, cylindrical, with a circle of simple filiform tentacula. Cells very small, indistinct externally, contiguous, with an oblique (operculated?) opening. The polyparium formed of these cells in one series is a leaf-like expansion, and composed of ramifications which anastomose into a network, and bear the openings of the cells on the inner face only.

Example (recent), Retepora cellulosa. Ellis, 'Corallines,' t. 25, d. D.



Retepora cellulosa.

Whether the fossil species admitted by Lamarck, Blainville, and Defrance, really belong to the genus, we are ignorant; but very many of those referred to this genus by Goldfuss and Phillips, from the carboniferous limestone and older strata, have a most decided analogy to it. Some of them, when of a conical shape (as, if perfect, many are), exhibit the openings of the cells not on the inner but on the outer face. (*Geology of Yorkshire*, vol. ii., pl. 1.) The late Mr. Miller of Bristol proposed (in MS.) for fossils of the same type found in the transition limestone to constitute a new genus, and Mr. Lonsdale, adopting this view and using the convenient name of Fenestella, has given characters for the group. (*Silurian System*, p. 677.) From a careful study of many species of this type, we offer the following abridged generic character:—

Fenestella (fossil), Lonsdale.

Animals unknown. Cells very small, indistinct externally, with small (prominent) openings. The polyparium formed of these cells is a leaf-like (often infundibuliform) expansion, composed of ramifications radiating from a centre, bearing each two rows of openings from the cells on the outer face only, and connected by transverse bars into a reticulated structure.

Example, Fenestella prisca. Lonsdale, 'Silurian System,' pl. 15. From the Wenlock rocks.

The species occur chiefly in the 'upper transition' or Silurian rocks of Shropshire, Dudley, Devonshire, the carboniferous rocks of England and Ireland.

Verticillipora (fossil), Defrance.

Cells poriform, arranged in reticulation on the surface of convex imbricating plates round a hollow axis, so as to form a fixed irregularly subcylindrical polyparium.

Example, Verticillipora cretacea, Defrance. Blainville, t. 66, f. 1. From the chalk.

(To this rather obscurely characterised genus Mr. Lonsdale assigns a species from the Silurian rocks.)

Dactylipora (fossil), Lamarck.

A regular cylindroidal tubular body, rounded at both extremities, with a round orifice at one margined by a fimbriated lip or border; both inner and outer surface reticulated by numerous infundibuliform holes, the partitions between which are pierced by pores supposed to be orifices of the polypiferous cells.

Only one species of this singular and elegant coral (if such it be) is known, viz. D. cylindracea, from the tertiary strata. Blainville, pl. 72, f. 4.

Conipora, Blainville.

An obconical or pyriform hollow body, composed of a thin crust pierced by many quadrangular holes arranged in quincunx.

One species, Conodictyum striatum, Goldfuss (tab. 37, f. 1). From the Jura-kalk of Baireuth.

Ovulites (fossil), Lamarck.

An oviform or cylindrical hollow body perforated at each extremity, and covered by scattered irregular, polygonal, very fine pores.

Lamarck, who constituted the genus, describes two species, O. margaritula, and O. elongata, both from the tertiary strata of Grignon.

Polytrypa (fossil), Defrance.

A subcylindrical fistulous mass, perforated at each extremity, and pitted within and without with round pores (the openings of short cells) very closely set, and arranged in rings, especially on the inner face. (Allied to Dactylipora.)

Example, Polytrypa elongata, Defrance. From the tertiary strata of Valognes. Blainville, pl. 73, f. 1.

Vaginopora (fossil), Defrance.

General form a hollow, external, cylindrical cellular crust, enveloping but not touching an internal hollow tube. The cells of the external crust are hexagonal and united in quincunx, with a small round subcentral orifice; those of the inner tube are elongated and ranged in rings. (It is not unlikely that the union of the two tubes in one specimen is accidental. Only one species, V. fragilis, and of that only a fragment, was known to Defrance, from the tertiary beds of Parnes.)

Larvaria (fossil), Defrance.

A cylindrical, antenniform, fistulous body, composed of celluliform grains arrayed in rings, and leaving between them circular rows of round pores which penetrate through the mass to the interior cavity.

Example, Larvaria reticulata. Defrance, from the tertiary strata of Grignon. Blainville, p. 71, f. 3.

Palmularia (fossil), Defrance.

A fixed oval elongated body, flattened, and smooth on one (probably the lower and adherent) side, and ornamented above and on the sides with two oblique rows of small celluliferous ribs, which denticulate the border.

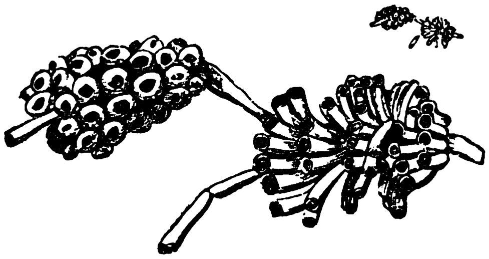
Example, Palmularia Soldani. Defrance, from the tertiary strata of Grignon. Blainville, pl. 68, f. 6.

Concerning the genera Palmularia, Larvaria, Vaginopora, Polytrypa, Ovulites, Conipora, Dactylopora, it is to be remarked that doubts have been expressed as to their really belonging to the Polypiaria at all. The discussions on this subject in Blainville's 'Actinologie' do not entirely clear up the subject.

Cellepora, Lamarck.

Animals provided with eight simple tentacula and two openings to the intestinal canal. Cells complete, circumscribed, urceolated, tumid, with a round operculated terminal opening. The polyparium which they form by their irregular accumulation is of a spongy and porous consistence, and appears either encrusting other bodies or rising into ramose masses like a madrepore.

Example, Cellepora pumicosa, Linn.



Cellepora Pumicosa.

Goldfuss mentions many fossil species, from the antient as well as most recent strata.

Cadosus, Savigny.

Polyparium orbicular, lapidescent, plano-convex, pierced above with central and scattered pores.

Example, Cadosus imbutiformis.

Berenicea, Lamouroux.

Animals unknown. Cells submembranous, prominent, ovoïd, separated, with a round subterminal opening; scattered irregularly or in a radiating manner on the surface of a thin attached crust.

A subdivision of the old genus Cellepora, proposed by Lamouroux.

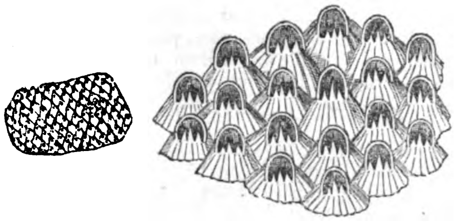
Example, Berenicea diluviana. Fossil from Caen. (Lamx., 'Gen. Polyp.,' tab. 82, f. 1.)

Discopora, Lamarck.

Animals unknown. Cells complete, prominent, more or less with a round terminal operculated opening. The polyparium found by their union in one series is a very small and thin crust.

(A subdivision of Cellepora proposed by Lamarck.)

Example, Discopora verrucosa, Lamarck.



Discopora verrucosa.

Membranipora, Blainville.

Animals hydriform. Cells circumscribed, not prominent, closed above by a thin fugacious membrane in which the round opening is pierced. The polyparium formed by their union is membranaceous, and spreads in a lamina on the surface of marine bodies.

Example, Flustra membranacea of Linnæus.

Blainville states that it is not certain that all the species are operculated. If not operculated, they should be carried to the next great family, and perhaps reunited to Flustra. Several of Goldfuss's fossil Celleporæ are referred to this genus by Blainville.

Fam. 2. *Cellariæa.*

Animals hydriform, separate, distinct, with very fine tentacula. Cells oval, depressed, membranous with a bilateral opening which is not terminal. The polyparium which they form by their union laterally or in two rows, is membranous, and fixed; (ovaria external?) no operculum. The Linnæan genus Cellaria is the type of this family, which ranks with the Zoophyta Ascidioïda of Johnston, and the Ciliobrachiata of Farre.

Genera.

Lunulites (fossil), Lamarck.

Cells in one series arranged in concentric circles on diverging radii, their openings being on one (the upper) surface. Polyparium regular, orbicular, convex above, concave below. (In the typical species the concave side is radiated.)

Example, Lunulites radiata, Lamarck. Blainville, pl. 75, f. 5.

Electra, Lamouroux.

Animals unknown. Cells membranous, vertical, bell-shaped, ciliated on the edges, closed by a membrane like a diaphragm, with a small semilunar opening, and united in a verticillate form round some other body, or in spike-like branches. (Closely allied to Flustra.)

Example, Flustra verticillata, Linn. Lamouroux, 'Polyp. flex.,' pl. 2, f. 2.

Flustra.

Animals provided with numerous simple tentacula, in one row. Cells complete, separate, depressed, with a thick stiff prominent margin, giving attachment to a membranous part, in which is a subterminal transverse opening. Arranged in quincunx, the cells unite to form a membranous flexible encrusting or frondescent polyparium.

This great genus is divided by Blainville into four sections, viz.: —

Encrusting, as Flustra dentata, membranacea, pilosa, &c.

Frondescent, formed of two series of cells, as F. foliacea, F. truncata, &c.

Frondescent, formed of one series of cells, as F. carbasea.

Narrowly lobed, with one series of cells, as F. avicularis, F. setacea, &c.

There are fossil species from the tertiary and perhaps older stratas.

Example, Flustra carbarea. Sol. and Ellis, 'Zooph.,' tab. 3, f. 6, 7.

Admirable figures of Flustra pilosa are given by Mr. Lister, in the 'Phil. Trans.' for 1834.

Elzerina, Lamouroux.

Animals unknown. Cells rather large, elongate oval, subhexagonal with raised margins, which support a membranous expansion, in which a sigmoial aperture appears. By a quincuncial and at the same time circular arrangement of the cells, a branching dichotomous fixed membranous polyparium is formed.

Example, Elzerina, Blainville. From Australasia. Blainville, pl. 80, f. 2.

Pherusa, Lamouroux.

Animals unknown. Cells oval, ending in a large prominent tubular opening, and arranged in oblique rows on only one face of a membranous (or subgelatinous) frondescent, flabelliform, fixed polyparium.

Example, Flustra tubulosa, Ellis. Lamouroux, 'Polyp flex.,' pl. 2, f. 20.

Vincularia (fossil), Defrance.

Cells oval, subhexagonal, regular, with a subterminal semilunar opening; united longitudinally in several rows, they form a slender brittle polyparium (en forme de baguette).

Example, Vincularia fragilis, Defrance. Blainville, pl. 67, f. 3.

Goldfuss, calling the genus Glauconome, describes two other species from the tertiaries of Westphalia, and one (probably not congeneric, but really allied to Fenestella) from the transition strata.

Cellaria.

Animals with an elongated contractile proboscis, a circle of twelve tentacula, and an internal ovarium. Cells regular (hexagonal or oval), with a transverse (subtubular) opening, arranged circularly in quincunx on the surface of the cylindrical dichotomous articulations of a subcalcareous plant-like polyparium, attached by horny tubes like roots.

Section 1, species which have hexagonal cells and a transverse opening (Salicornia of Cuvier).

Example, Cellaria Salicornia. Ellis, 'Corallines,' tab. 23. (Fleming makes it his genus Farcimia.)

Section 2, with oval cells, and tubular opening.

Example, Cellaria ceroïdes. Ellis and Solander, tab. 5, fig. 6, b. c.

Intricaria (fossil), Defrance.

Cells hexagonal, elongated, with a raised border covering all the surface of a rather solid polyparium, formed of cylindrical branches irregularly anastomosed.

Example, Intricaria Bajocensis, Defrance. From the oolite of Bayeux. Blainville, pl. 68, f. 1.

Canda, Lamouroux.

Animals unknown. Cells not prominent, rigid, subcretaceous, arranged in two alternate rows on one face of the branches, which are dichotomous, articulated, united by transverse fibres, so as to form a flabelliform polyparium.

Example, Canda arachnoidea, Lamouroux. (*Zooph.*, pl. 64, f. 19.) From Australia.

Caberea, Lamouroux.

Animals unknown. Cells small. Polyparium calcareous, plant-like, dichotomous, articulated, bearing on one side the cells arranged in quincunx, and on the other the continuation of the fistulous radicles by which it is attached.

Example, Caberea pinnata, Lamouroux. From Australia.

Tricellaria, Fleming.

Animals hydriform. Cells with an oval terminal opening, arranged in three rows on the articulations of the polyparium, which is plant-like, dichotomous, and fixed by radical fibres.

Example, Cellaria ternata, Solander and Ellis. European seas.

Acamarchis, Lamouroux.

Animals unknown. Cells cornuted, adpressed with a vesicle at the orifice, ranged in two lateral rows so as to compose the articulations of a horny plant-like dichotomous polyparium, fixed by radical fibres.

Example, Cellaria neritina, Linn. (Ellis, *Corallines*, t. 19, f. *a*, A, B, C.)

Bicellaria, Blainville.

Animals hydriform, with eight simple tentacula. Cells hardly prominent, arranged in two alternate rows, with their orifices on one face of the polyparium, which is of a cretaceous substance, plant-like, dichotomous, and fixed by radical fibres.

Example, Bicellaria ciliata. Ellis, 'Corallines,' t. 20, No. 5, *d*, D.

Crisia, Lamouroux.

Animals hydriform. Cells ending in a prominent tubular opening, arranged on two alternate rows of articulations of a plant-like dichotomous polyparium fixed by radical fibres.

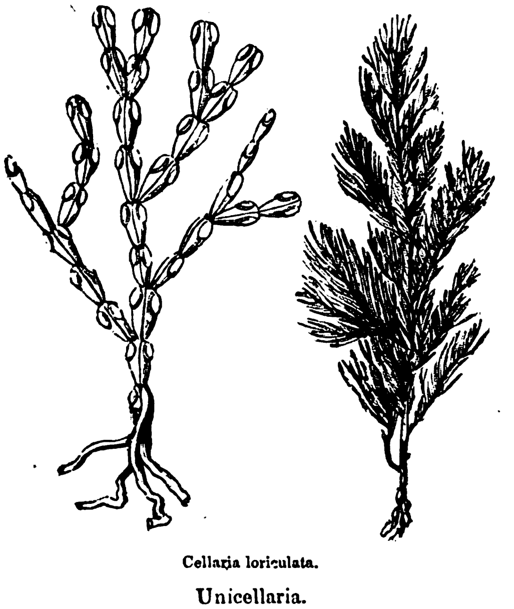
Example, Cellaria eburnea. Ellis, 'Corallines,' t. 21, No. 6, *fig. a*, A.

(This genus of Lamouroux included in that author's arrangement Bicellaria and Tricellaria.)

Gemicellaria, Blainville.

Animals hydriform. Cells oval, with an oblique subterminal opening, united two and two dorsally, so as to form the articulations of a plant-like dichotomous polyparium fixed by radical fibres. (Notamia of Fleming; Gemellaria of Savigny.)

Example, Cellaria loriculata. Ellis, 'Corallines,' t. 21, *fig.* 7, *b*, B



Cellaria loriculata.

Unicellaria.

Animals unknown. Cells elongated, with a terminal opening, forming one by one the articulations of a calcareous plant-like polyparium, fixed by radical fibres. (Eucratea and Lafœa of Lamouroux.)

Example, Unicellaria chelata. Ellis, 'Corallines,' t. 22, No. 9.

Catenicella, Blainville.

Animals unknown. Cells horny, oval, with their openings not terminal, growing one out of another, end to end, or laterally, and spreading over marine bodies in a reticulated or chain-like arrangement. (Hippothöe of Lamouroux?)

Example, Catenicella Savignii. Egypt: see the great work on Egypt ('Description de l'Egypte'). 'Zool. Polyp.,' pl. 13, f. 1.

Menipæa, Lamouroux.

Animals unknown. Cells oval, trifurcate; their orifice rounded, not terminal; arranged in one row on one side, and growing one out of another dichotomously, so as to form the articulations of as ubcalcareous plant-like polyparium, fixed by many radical fibres.

Example, Cellaria cirrhata. Ellis and Solander, t. 4, *fig. d*, D.

Alecto (fossil), Lamouroux.

Cells elongated, tubular, with an oval subterminal orifice, growing one out of another (dichotomously or singly), arranged in one row, and spread in a reticulated form on marine bodies.

Example, Alecto dichotoma, Lamouroux. (*Zooph.*, t. 81, f. 12-14.) From the oolite of Caen.

Fam. 3. *Sertulariæa.*

Animals hydriform, with simple (ciliated?) tentacula and external ovaria. Cells tubular, more or less tooth-like, forming part of a continuous horny subarticulated tube, which is traversed by a soft medullary axis, and fixed by radical tubules.

The Linnæan genera Tubularia and Sertularia constitute this very natural and beautiful family, which is included in the Zoophyta Hydroïda of Johnston, and the Nudibranchiata of Farre. The genera which follow, from Lamarck and Lamouroux chiefly, require much reconsideration.

Section 1. Tubulariæa.

Genera.

Anguinaria, Lamarck.

Animals unknown. Cells subcalcareous, solitary, tubular, or arched, with a large oval oblique subterminal opening, growing irregularly out of a horny anastomosed stem, which spreads on marine bodies. (Aetea of Lamouroux. Mr. Lister wishes it to be placed near Flustra.)

Example, Cellaria anguina, Linn. (Ellis, 'Corallines,' pl. 22, No. 11.)

Aulopora (fossil), Goldfuss.

Cells tubular, with a round opening, more or less projecting, anastomosed so as to form a polyparium, attached to and more or less rampant on marine bodies.

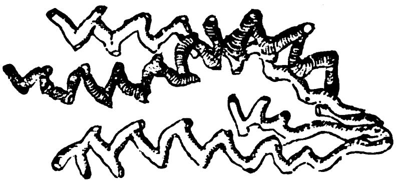
Example, Aulopora serpens, Goldfuss. ('Pétref.,' t. 39, f. 1.) Millepora dichotoma, Linn. From the Eifel limestone.

Mr. Lonsdale and Goldfuss give other species from the same formation in England, in the Eifel, &c., and others of rather different type are mentioned by Goldfuss, from the oolites of Franconia.

Tibiana, Lamarck.

Animals unknown. Cells cylindrical, tubular, united into an angularly bent tube, on the projecting angles of which are situated the round openings of the cells. The tubes are fasciculated, and reunited to a base fixed by radicles.

Example, Tibiana fasciculata, Lamouroux. ('Polyp. flex.,' pl. 7, *fig.* 3, *a*.)



Tibiana fasciculata.

Tubularia, Pallas.

Animals bearing a sort of proboscis projecting from the centre of a circle of ciliated tentacula. Cells infundibuliform, placed at the extremity of long horny simple or bifurcated tubes, which form by their assemblage a rooted polyparium. (Much allied to Campanularia.)

Examples, Tubularia indivisa. (Ellis, 'Corall.,' t. 16, f. *c*.) Tubularia ramosa. (Ellis, 'Corall.,' t. 17, f. *a*.)

Coryna, Gærtner.

Animals club-shaped: the upper oval part being covered with slender tentacula ending in suckers, and supported by a long simple or branched vertical attached stem. (Linnæus ranked them with Tubularia (a confused genus in his arrangement); Müller with Hydra, and Lamarck places Coryna near Hydra, giving further to it the character of a terminal mouth.)

Example, Coryna squamata, Pallas.

Here come the genera Corynomorpha of M. Sars, Syncoryna of Ehrenberg, and Pedicellina of Sars. In the latter both the mouth and anal orifice are at the upper extremity of the oval expansion.

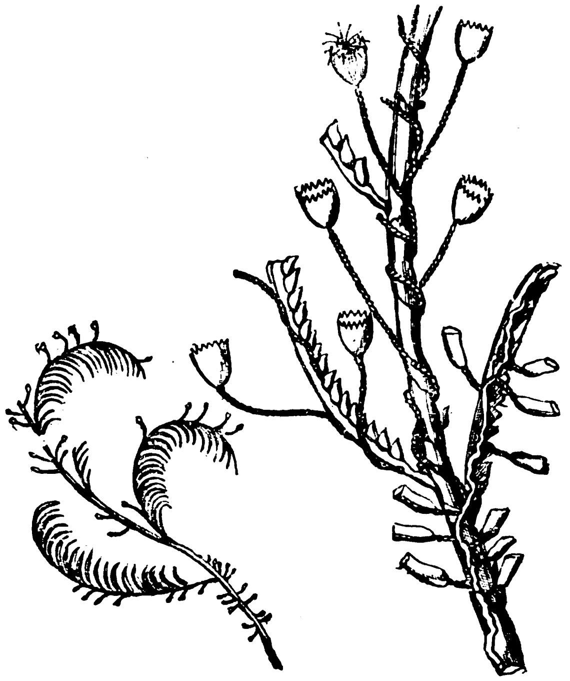
Section 2. Sertulariæa. (Genus Sertularia of Linn.)

Campanularia, Lamarck; Clytia, Lamouroux.

Animals bearing a simple circle of ciliated tentacula. Cells urceolated, pedunculated, attached along a common filiform, branching, twisting, or climbing axis.

Div. 1. Axis climbing.

Example, Campanularia volubilis. (Ellis, 'Corallines,' t. 14, *fig. a*, A.)



Campanularia volubilis.

Div. 2. Axis not climbing.

Example, Campanularia rugosa. (Ellis, 'Corallines,' t. 15, *fig.* 23.)

Laomedea, Lamouroux; part of Campanularia, Lamarck.

Animals with twelve ciliated tentacula. Cells pedunculated, scattered on the branches of a plant-like polyparium, fixed by radical fibres.

A. Stem simple; cells scattered.

Example, Laomedea fruticosa, Esper. ('Zooph.,' t. 34, *fig.* 1, 2.)

B. Stem simple; with alternate cells.

Example, Sertularia dichotoma, Linn. (Ellis, 'Corall.,' t. 12, *fig. a, c.*)

C. Stem complex; cells scattered.

Example, Laomedea dumosa, Johnston. (Ed. *Ph. Journal*, xiii., t. 3, f. 2, 3.)

D. Stem complex; cells alternate.

Example, Sertularia gelatinosa, Linn. (Ellis, 'Corall.,' t. 12, *fig. c, c.*)

E. Stem complex; cells verticillate.

Example, Sertularia verticillata, Linn. (Ellis, 'Corall.,' t. 13, *fig. a*, A.)

Vesicularia spinosa, Thompson. Valkeria spinosa, Fleming, is arranged in this latter subdivision by Blainville. (See Dr. Farre's drawings of this species in 'Phil. Trans.,' for 1837.)

Serialaria, Lamarck; Amathia, Lamouroux.

Animals unknown. Cells very distinct, conical, almost tubular, placed in series on one side of the articulations of the fistulous branched and fixed polyparium.

A. Cells grouped.

Example, Serialaria lendigera. (Ellis, 'Corall.,' t. 5, No. 24.) Europe.

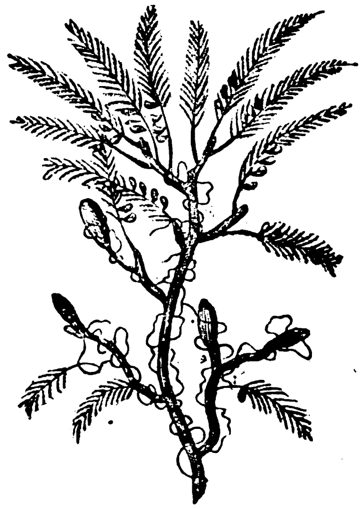
B. Cells in a spiral.

Example, Serialaria spiralis, Lam. Australia.

Plumularia, Lamarck; Aglaophenia, Lam.

Animals with 15-18 ciliated tentacula. Cells very distinct, axillary, arranged on one side of the small branches of a fistulous articulated penniform polyparium, which is fixed by many tubular radical fibres.

Example, Sertularia pluma, Linn. (Ellis, 'Corall.,' t. 7, No. 12.)



Sertularia pluma.

Dr. Fleming proposes to divide this large and beautiful genus into two groups, according as the stems are simple (as in the above species), or compound, as in Plumularia myriophyllum. The works of Ellis, Lamouroux, and Dr. Johnston may be consulted for the drawings of the species, of which several are British.

Sertularia, Lamarck.

Animals having ciliated tentacula. Cells sessile, urceolate, arranged alternately or in pairs obliquely (not exactly opposite) on the stem and branches of the polyparium, which is horny, fistulous, generally bent in zigzag, and attached by radical fibres.

Thus circumscribed and reduced to a mere fragment of the great Linnæan genus, Sertularia still includes many species from the European and Australian seas.

Example, Sertularia Polyzonias, Linnæus. Ellis, 'Corallines,' pl. 2, No. 3.

Biseriaria, Blainville; Thujaria, Fleming.

Animals unknown. Cells turbinated, sessile, not prominent, touching and placed in two rows along the ramifications of the horny plant-like polyparium, which is fixed by radical fibres.

Example, Sertularia Thuja, Linnæus. Ellis, 'Corallines,' pl. 5, No. 9.

Idia, Lamouroux.

Animals unknown. Cells oval, rather recurved, closely ranged on two alternate rows, and projecting on the sides of the branches (themselves alternating) of a plant-like fixed polyparium.

Example, Idia pristis, Lamouroux. 'Polyp. flex.,' pl. 5. Australia.

Tuliparia, Lamarck; Pasythea, Lamouroux.

Animals unknown. Cells arranged in pairs and small groups in each articulation of the polyparium, which is connected to a repent stem.

Examples, Sertularia tulipifera, Gmelin (cells pedunculated); Sertularia quadridentata, Gmelin (cells sessile).

Antennularia, Lamarck; Nemertesia, Lamouroux.

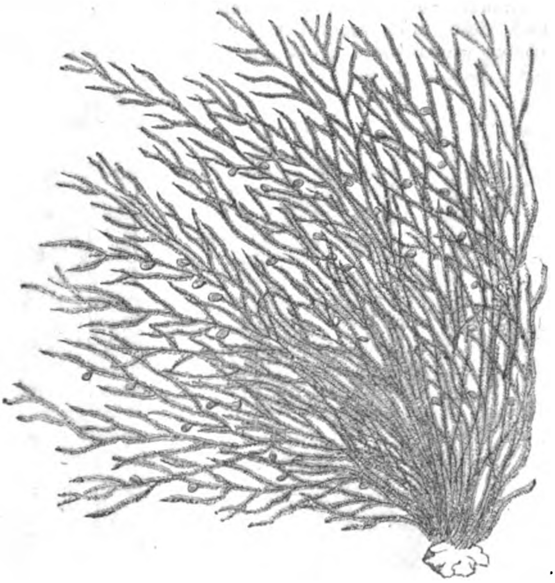
Animals with eight tentacula. Cells minute, indistinct, opening on the inside of ciliated articulations, which are arranged in whorls round a fistulous horny stem rising from root-like fibres.

Example, Antennularia indivisa. Ellis, 'Corall.,' pl. 9, a.

Dynamena, Lamouroux.

Animals with twelve simple tentacula. Cells urceolate, or tooth-like, sessile, arranged in pairs (regularly opposite) and prominent along the branches and stem of a horny, articulated, plant-like, fistulous polyparium, which is attached by creeping radical fibres.

Example, Dynamena operculata. Ellis, 'Corallines,' pl. 3, No. 6.



Dynamena operculata.

This genus, rich in British species, is separated from Sertularia by convenient rather than by important distinctions.

Cymodocea, Lamouroux.

Animals unknown. Cells filiform, lengthened, regularly opposed two and two, and transversely, on horny fistulous stems, which are attached by a broad thin base.

Example, C. ramosa, Lamouroux. 'Polyp. flex.,' tab. 7, f. 1. West Indies.

Salacia, Lamouroux.

Animals unknown. Cells dentiform, minute, oval, verticillate four and four, along the tubular branches of a horny plant-like fixed polyparium.

Example, Salacia tetracythara, Lamouroux. 'Polyp. flex.,' tab. 6, pl. 3. Australia.

Thoa, Lamouroux.

Animals elongated, having twelve simple tentacula, and mostly projecting beyond the cells. Cells dentiform, minute, indistinct, alternate on the sides of the compressed branches of a horny stem formed of interlacing tubes, the lower ones root-like.

Example, Sertularia balecina, Gmelin, Fleming.

Entalophora (fossil), Lamouroux.

Cells elongate, dentiform, recurved, with a round terminal opening, scattered on a plant-like, slightly ramose, fixed polyparium.

Example, E. cellarioides, Lamouroux. 'Gen. Polyp.,' tab. 80, f. 9. Caen.

POLYPIARIA DUBIA.

Genera.

Cristatella, Cuvier.

Animals short, growing irregularly from a common unattached basis. Many ciliated tentacular cirri, arranged anteriorly in a lunate or horseshoe form, with the mouth in the middle of the branches. A median opening at the base of the dorsal region.

Example, Cristatella vagans, Cuvier. Blainv., pl. 85, f. 7.

Alcyonella, Lamarck.

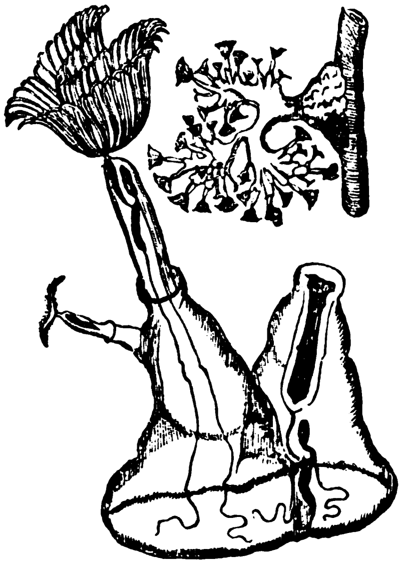
Animals hydriform, retractile into a fixed suberose polyparium, composed of vertical subpentagonal tubes full of granular corpuscles. Many tentacula arranged in a horseshoe figure.

Example, Alcyonella stagnorum, Lamarck, Blainville, pl. 85, f. 8.

Plumatella, Bosc; Naisa, Lamouroux.

Animals short, capable of retraction, projecting from a sort of rampant attached thallus. Two fasciculi of unequal tentacular cirri, forming a horseshoe figure, in the midst of which is the mouth.

Example, Plumatella cristata, Lamarck. 'Polype à panache,' Trembley, pl. 10, f. 8, 9.



Plumatella cristata

Difflugia, Leclerc, Lamarck.

Body small, gelatinous, contractile, enclosed in a sheath of an oval subspiral figure, extended into a straight termination and covered with arenaceous grains. Tentacula unequal, retractile.

Example, Difflugia proteiformis, Lamarck. Blainville, pl. 85, f. 5.

It is perhaps still uncertain what may be the exact relation between the four genera of fresh-water Polypiaria just enumerated. The strong analogy between them is admitted by all modern writers, and M. Raspail, in Memoirs read to the Academy of Sciences, has endeavoured to prove that they are all one and the same animal in unequal states of development, a proposition since controverted on good grounds by M. de Gervais, Mayer, Ehrenberg, &c.

Dædalæa (marine), Quoy and Gaimard.

Body ovoid, glandiform, with long simple subradiating tentacula. Cells of the same form, transparent, attached in irregular groups on a cylindrical axis of gelatinous or membranous substance, which bifurcates or trifurcates and anastomoses into an irregular unattached reticulation.

Example, Dædalæa mauritiana, Quoy and Gaimard. Blainville, pl. 81, f. 6.

POLYPIARIA NUDA.

Under this division, only the genus Hydra (which see) is retained by Blainville. Lamarck included Hydra, Coryna, Pedicellaria, Zoanthus. Regarding Pedicellaria, which is attached to the shells of Echini, it is perhaps a part of the Echinodermatous structure. Coryna is included in Polyp. membranacea. Zoanthus is closely related to Actinia.

POLYPIARIA CORTICIFERA.

Lamarck has grouped under this title a family of Polypiaria for the most part very natural. Ramified into an arborescent form from a fixed base; composed of two separate parts, an external living fleshy envelope bearing and containing polypi, and an internal firm solid inorganic axis; these corticiferous Polypiaria, as Lamouroux also calls them, are in general easily recognised. Lamarck gives only six genera, viz. Corallium, Melitæa, Isis, Antipathes, Gorgonia, Corallina. (Whether the latter should be ranked with plants, as many moderns think, or compose a separate group of Zoophyta (Calciferous Corallines of Lamouroux) is uncertain; they are not rightly placed with corticiferous Polypiaria).

Lamouroux omits from the group Corallinæ, to constitute a separate section, but introduces rather awkwardly the group of Spongiæ. Augmenting Lamarck's genera, he gives of true Corticifera eleven types, viz. Anadyomena, Antipathes, Gorgonia, Plexaura, Eunicea, Muricea, Primnoa, Corallium, Melitæa, Mopsea, Isis. (*Exposition des Polypiers.*)

Cuvier, taking a different view of the bounds of the group, notices the interior conformation of the animals, whereby they approach to Actinia, and adopts the following classification:—

Polypiaria corticifera—1. Ceratophyta with a horny axis.
    Antipathes.
    Gorgonia—Plexaura, Eunicea, Muricea, Primnoa.
    2. Lithophyta with stony axis.
    Corallium, Melitæa, Isis, Mopsea.
    (Madrepora, &c. &c.
    Millepora, &c.) These are quite misplaced.
    3. Natantia.
    Pennatula, &c.
    4. Alcyonea.
    Alcyonium, Tethya, Spongia.

Dr. Johnston, in his valuable work on British Zoophytes (1836), has arranged them very conveniently in the order of *Asteroïda.*

Blainville places the Corticifera in his class of Zoophytaria, which includes the families—1, Tubiferæa; 2, Corallia; 3, Pennatularia; 4, Alcyonaria or Sarcoidea.

The family of *Corallia* exactly corresponds to Polypiaria corticifera of Lamarck properly limited. The Alcyonaria are equivalent to Lamarck's Polypi tubiferi, with Alcyonium added, as Latreille has very properly done (*Familles Naturelles,* p. 543). We shall supply under the title SARCOIDEA what is required in addition to the article Alcyonium. PENNATULARIA and TUBIFERÆA form separate articles, and some general observations may be added under ZOOPHYTARIA.

The Corallia, or true corticiferous Polypiaria, are thus explained by Blainville:—

Animals hydriform, with internal ovaria, and eight (pinnated?) tentacula irregularly scattered on the surface of a compound polyparium, formed externally of a living gelatinoso-cretaceous substance, and internally of a solid horny or calcareous axis, concentrically laminated. The base of attachment is large.

Genera.

Corallium, Lamarck.

Cells immersed in a *thin* external fleshy integument; axis thick, stony, solid, striated, ramified, and fixed by a broad base.

Example, Corallium rubrum (Gorgonia nobilis, Linn.). Ellis and Solander, pl. 13, fig. 3, 4.

This, the only species, is the common red coral of the Mediterranean.

Mopsea.

Animals with eight ranulose tentacula. Cells immersed in the integument. Axis stony, articulated, the articulations ramified, and separated by horny intervals giving origin to branches.

Example, Mopsea dichotoma (Isis, auct.).

Melitæa, Lamouroux.

Animals unknown, scattered in a soft, fleshy, thin integument. Axis arborescent, ramified, composed of stony substriated articulations, separated by spongy tumid intervals. (Colour red.)

Example, Melitæa coccinea. Sol. and Ellis, tab. 12, f. 5.

Gorgonia.

Animals with eight ovarian orifices; cells scattered in a thin integument; axis plant-like, solid, of a horny substance, fixed by a wide base.

A. Cells not prominent.

Example, Gorgonia patula. Ellis and Solander, tab. 15, fig. 3, 4.

B. Cells prominent, pustulous.

Example, Gorgonia flabellum. Ellis, 'Corall.,' tab. 26, fig. A.

C. Cells prominent, recurved.

Example, Gorgonia florida. Muller, 'Zool. Dan.,' t. 137.

The fossil species from transition strata, referred to this genus by Goldfuss, are mostly transferred to Retepora and Fenestella.

Eunicea, Lamouroux.

Animals with short tentacula. Cells mammillated, dispersed or ranged in lines on the surface of the branches. External integument thick, cylindrical; axis horny. (This genus is not adopted by Lamarck.)

Example, Eunicea mammosa, Lamarck. 'Polyp. flex.,' pl. 17.

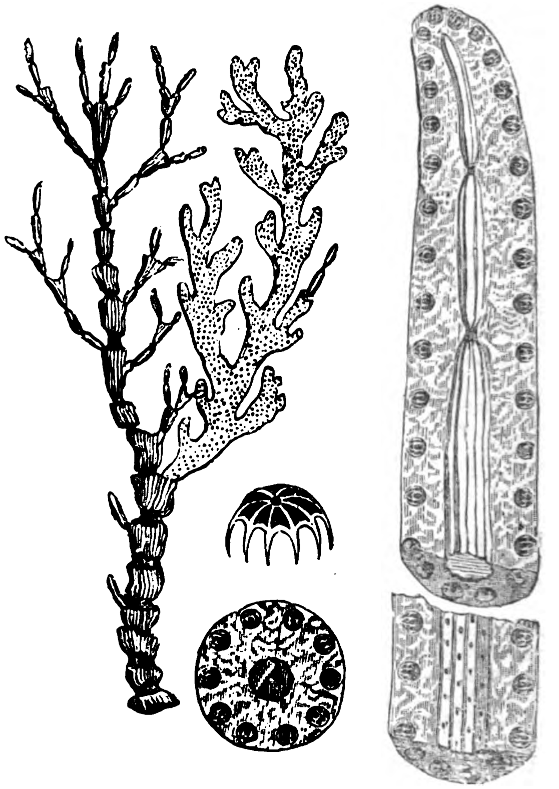
Funicula, Lamarck.

Animals papilliform, ranged in lines alternately on each side along a very slender body, composed of a thin integument and a horny axis. (Lamarck placed the genus among the Pennatularia.)

Example, Funiculina cylindrica, Lamarck. Blainville, pl. 90, f. 4.

Isis.

Animals very small, abundantly scattered in the soft thick fleshy integument. Axis arborescent, composed of striated calcareous articulations separated by horny intervals. Base attached.



Isis hippuris.

Example, Isis hippuris, Linn. Ellis and Solander, 'Zooph.,' tab. 3, fig. 1-5.

There are a few fossil species from tertiary strata.

Plexaura, Lamouroux.

Cells not prominent, immersed in a very thick integument, of a substance like cork when dried; axis arborescent, often dichotomous, horny, fixed.

Example, Plexaura suberosa. Ellis, 'Corall.,' tab. 26, P, Q, R.

Muricea.

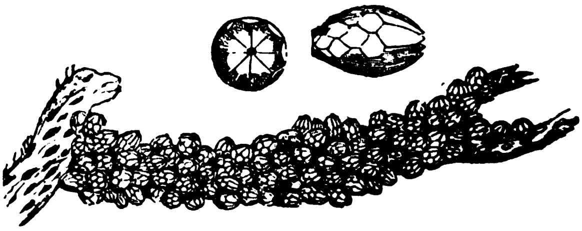
Animals forming prominent zonical mammillæ of a squamose and tubular structure, scattered on the surface of the subdistichous branches of a plant-like polyparium. Integument thick, axis horny and cylindrical except at the origin of the branches.

Example, Muricea muricata, Lamouroux. 'Expos. Méthod.,' tab. 71.

Primnoa, Lamouroux.

Animals forming prominent elongated mammillæ of a squamose structure; polyparium dendroidal, dichotomous; integument thin; axis horny and very hard.

Example, Gorgonia lepadifera, Linn. Blainville, pl. 87. From Norway.



Gorgonia lepadifera.

Antipathes, Pallas.

Animals scattered in a thick gelatinous integument which falls off on drying); polyparium horny, flexible, solid, often spinose, branched. Pallas says there are external turbinated ovaria. Mr. Gray assigns to them six tentacula.

Example, Antipathes ulex. Ellis and Solander, tab. 19, f. 7, 8.

Cirripathes, Blainville.

Animals very small, with six wrinkled tentacula (not pinnated?) immersed in a thin gelatinous integument; axis horny, simplé, fistulous; polyparium conical, elongated, cirriform, with rows of spines. Mouth projecting and lobed.

Example, Antipathes spiralis, Linn. Ellis and Solander, tab. 19, fig. 1-6.

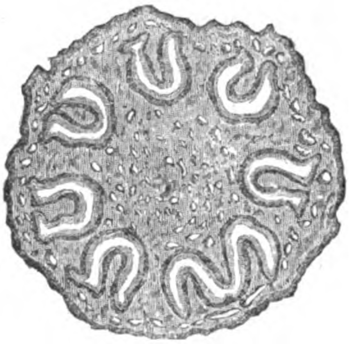
POLYPLAXI'PHORA. [CHITONS.]

POLYPLECTRON. [PAVONIDÆ, vol. xvii., p. 337.]

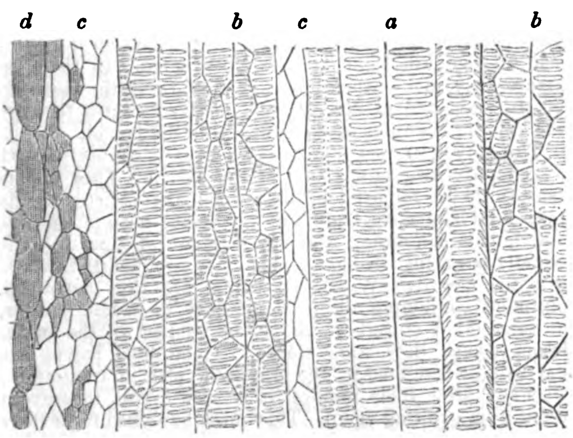
POLYPODIA'CEÆ are one of the chief divisions of the natural order of ferns, and may be conveniently taken as the type of the whole. They constitute the highest form of Acrogenous or Cryptogamic vegetation, and are regarded as approaching more nearly to Cycadaceous Gymnosperms than to any other part of the vegetable kingdom now in existence.

They are usually herbaceous plants, with a permanent stem, which either remains buried and rooting beneath the soil, or creeps over the stems of trees, or forms a scarcely moveable point of growth round which new leaves are annually produced in a circle, or it rises into the air in the form of a simple stem, bearing a tuft of leaves at its apex, and sometimes attaining the height of fifty or sixty feet.

The interior of the stem consists of a centre of cellular substance, which often disappears, and among which bundles of fibro-vascular tissue are sometimes mixed; beyond the cellular centre lies a zone of woody hard plates, which are much folded and plaited, which communicate with the petioles of the leaves, and which commonly present a horseshoe appearance when cut across; each of the woody plates is soft in the interior, where the texture principally consists of scalariform and pitted vessels and cells, as is seen in the accompanying figure of a highly magnified slice of *Cyathea Schanschin*, where *d* represents a portion of the hard coloured cells that constitute the wood, properly so called, *c* loose cells, *a* scalariform vessels, and *b* pitted tissue.



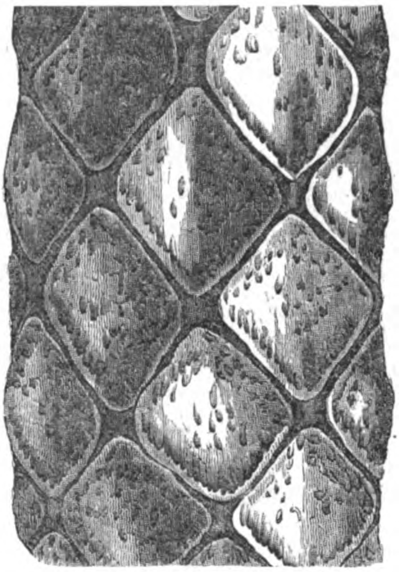
Section of stem of Alsophila vestita.



The whole of these parts are covered over with a hard cellular integument, which stands in the room of bark, and which is in reality a merely hardened portion of the general cellular tissue of the trunk.

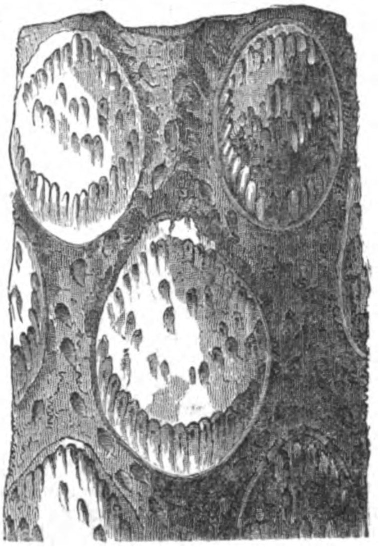
The stems seem always to produce roots in great quantities from their surface, even when elevated in the air; such roots are more especially met with near and under the ground, where they form a stratum of some thickness, acting both as feeding organs and as an external protection; on all Tree-ferns they appear upon the stem at least in the form of tubercles; and in *Cibotium Billardieri* they cover over the whole surface from the top to the bottom with a dense layer several inches deep.

The surface of Tree-fern stems may be taken to represent that of the order in general. It is always marked with scars of considerable size, having either a lozenge form or that of an irregular oval, and bearing within their area evident traces of the fracture of woody plates which passed from the stem into the leaves.



Portion of stem of Chnoophora excelsa.

These scars lengthen as the stem increases in age, till the lozenge or oval form is entirely destroyed; the scars then become separated to considerable distances, and extended into long and often irregular and indefinite spaces separated by deep furrows. Hence it happens that the appearance of the upper and lower end of the same tree-fern stem is so dissimilar, that they would not be supposed to belong to even the same species. Below the scars, or interposed among them, are found openings down into the interior of the stem, filled with pulverulent matter, and of unknown use. They appear to be of the same nature as the apertures into the superficial cells of Sphagnum, or more especially as the perforations in the rhizoma of Nymphæa. The next figure shows the appearance of such apertures in *Alsophila vestita*.



Although tree-ferns are unknown in any countries except those having either a damp tropical climate, or at least an equable mild temperature and humid atmosphere, yet the common ferns of this country, whose stems, vulgarly called roots, are formed under ground, exhibit the same kind of organization as that just described, only in a less conspicuous manner. It does not therefore follow that the remains of tree-ferns found in this country in a fossil state prove Great Britain to have had formerly a tropical climate, especially as the number of such remains hitherto met with has been extremely small; the utmost value that can be assigned to their evidence is that of probability. In those tropical lands where the tree-fern acquires its full size, as for example Brazil, the Philippines, Pitcairn's Island, &c., it becomes one of the most majestic and graceful objects, having an enormous plume of the most delicate and verdant foliage at the extremity of a lofty flexible stem, which sways beneath the gentlest breeze.

Chnoophora excelsa.

The leaves of ferns, called their fronds by Linnæus, are inserted upon the stem by an angular base, which is never extended at the sides into a sheath, as in palms; they are often of very considerable size, and cut into a multitude of divisions by repeated pinnation—this is especially the case with those of tree-ferns. The leaves are however often very small, and undivided. They are penetrated by veins, which are either simple or divided in a forked manner; many instances of netted leaves are however known, more especially in the genus *Hemionitis*. Their surface is provided with stomates, or breathing pores.

The fructification of ferns consists of hollow cases, called *sporangia*, generated upon the surface of the under side of the leaves, or below its epidermis, which latter is then ruptured in a definite manner, and the portion so divided from the rest is called the *indusium*. Each sporangium contains a number of granular particles, or spores, by means of which the fern is multiplied. There are no traces of sexual organs; for although Hedwig and others have fancied that they found male organs in various parts of the back of the leaves of ferns, such observations do not at all agree with each other, and have met with but little credit. The most common opinion is that certain small bodies of a cellular transparent texture, found among the sporangia when very young, are really stamens; but althought he existence of such organs is well known, there is not the smallest evidence of their possessing the attributes of a stamen.

The number of ferns known to botanists is considerable, and their classification has been found a subject of great difficulty. It has been attempted, with various degrees of success, by Swartz, Smith, Kaulfuss, A. Brongniart, Schott, and others; the most recent and apparently the best classification is that of Presl, published under the name of *Tentamen Pteridographiæ*, at Prague, in 1836. See also Mohl, *De Structura Filicum;* A. Brongniart, *Histoire des Végétaux fossiles*, i. 392; and Endlicher, *Genera Plantarum*, p. 58.

PO'LYPUS is a morbid growth attached to the interior of one or other of the mucous canals, by a more or less narrow pedicle. Polypi occur most frequently near the orifices of external communication of the mucous canals, as in the uterus, the fauces, the larynx, and the nose. A description of those that grow in the last of these situations may serve for all.

Polypi of the nose are of four kinds, which are named respectively, vesicular, gelatinous, fibrous, and malignant. Vesicular polypi are grey or yellowish transparent vesicles, containing a clear watery fluid with a little mucus; they are very soft, easily break down when they are pressed, and are liable to considerable increase of size when the evaporation from them is decreased in damp weather. They appear to consist of enlarged mucous follicles. Gelatinous polypi are more solid growths, consisting of dull white masses attached to the mucous membrane of the nose, and themselves covered by a fine but rather tough membrane. They seem composed of an excessive growth of the mucous membrane infiltrated with fluid, and having a few fibres running through its substance. Fibrous polypi are still more solid growths; they consist of a dense fibrous and vascular tissue, which it is often difficult to cut through, and which is sometimes converted into bone. They are usually intimately connected with the deeper parts of the mucous membrane. Malignant polypi are growths of a cancerous nature from the mucous membrane, which have received the name of polypi rather from having the same situation as the preceding than from their similarity of form. They may assume the characters of simple or scirrhous cancer, but more commonly they have those of the soft or medullary variety [CANCER] which is frequently called fungus hæmatodes.

The common symptoms of all polypi of the nose are that the patient is unable to breathe through the nostril in which they are placed, and has a nasal voice; there is usually a discharge of watery mucus, a loss of smell, and a diminution of the power of taste. If situated far back in the nose, they may cause deafness or obstruct the swallowing of food. They even render the breathing difficult. The softer kinds seldom produce worse effects than these, for their growth is restrained by the firm tissues of the nostrils; but the two last and firm varieties will continue to increase, expanding the bones and other tissues of the nostrils and face into huge and hideous swellings, and producing death either by their ulceration, or by their pressure on the vessels of the brain, or on the brain itself through the base of the skull.

The most usual situation of polypi is in the upper and back parts of the nostrils; and almost always on the outer wall, the septum being very rarely affected. In their increase they mould themselves to the form of the passages of the nose, and at last protrude either forwards through the anterior openings or backwards into the fauces.

The growth of vesicular polypi is usually connected with a generally disordered state of the health. They seldom require to be removed by operation; the patient should take mild alterative and tonic medicines with purgatives, and lotions containing alum or sulphate of zinc, or some equally powerful astringent, should be frequently injected into the nostrils. When the polypi are thus destroyed, ointment containing nitrate of mercury, or savine powder, or some other stimulant, should be rubbed on the membrane where they were seated. Gelatinous polypi are not usually benefited by the preceding plan of treatment; although after their removal it is very useful to prevent them from growing again. They must be pulled from their attachment by forceps, which should have rough blades, and, if possible, be placed around the pedicle of the growth, and withdrawn with a kind of twisting motion. All the polypi being thus removed, the mucus membrane should have some powerfully astringent lotion or ointment applied to it. The fibrous polypi usually require a more difficult operation for their removal; when they can be withdrawn by the forceps, it is only with much difficulty, from their being seated far back in the nostrils, and with some violence and danger of hemorrhage. In some cases a ligature may be tied round the base of such a polypus so as to make it slough off; in others they must be cut out with the knife or scissars. The choice of these operations must be made according to the circumstances of each case. After their removal, the same means should be adopted to prevent their return as in the preceding cases. The malignant growths in the nose, like those in other parts of the body, where their early and complete removal cannot certainly be accomplished, had better be treated only by palliative measures.

POLYSTOMELLA. [FORAMINIFERA, vol. x., p. 348.]

POLYTHALAMA'CEA. Under the title of CEPHALOPODA will be found notices of the principal modes of classification adopted for the numerous fossil and few recent testaceous bodies allied to Nautilus, Spirula, and Sepia. Many of the genera of this great division of molluscous animals are also noticed in their appropriate places, as BACULITES, BELEMNITES, BELLEROPHON, CORNU AMMONIS, GONIATITES, and, above all, NAUTILUS, by the investigation of which, in a living state, Professor Owen has been enabled to clear away much of the obscurity which overhung the history and affinities of fossil Cephalopoda.

It is proposed to sketch in this article a brief outline of the state and progress of investigation into the affinities and geological distribution of the leading groups of the Polythalamaceous Cephalopods, which may be ranked in the following four families, viz.:—

Tetrabranchiata. Fam. 1. Nautilidæ.
2. Ammonitidæ.
Dibranchiata. Fam. 1. Spirulidæ.
2. Belemnitidæ.

So large a proportion of the components of these families are in a fossil state, that it is necessary to base a view of their relations on the conservable testaceous parts principally, always however keeping in mind the probable uses of the parts, as determined by investigation of the recent forms most nearly comparable.

Nautilidæ.

Three principal considerations have guided the geological naturalists, to whom principally the divisions of the Nautiloidal Cephalopoda are due, in the arrangements which they have proposed:—

1. The spirality of the shell. In Nautilus it is involute or convolute; in Orthoceras straight; and between perfect involution and absolute straightness, we have every degree of curvature.

2. The form in which the septa, whereby the cavity becomes concamerated, meet the inner surface of the shell. In most Nautili this is a gentle and simple curve; in many Orthocerata it is waved; in many Clymeniæ undulated, or deeply and angularly notched.

3. The situation of the siphuncle on the disk of the septa. In most Nautili the siphuncle is nearly in the centre of the disk; in Clymeniæ it is on or near the inner or ventral edge; in Cyrtoceras generally near to the outer or dorsal line.

To these Mr. C. Stokes (*Geol. Proceedings*) has added, in the case of the Orthocerata, the consideration of the form of the siphuncle itself; and Mr. Broderip (*Silurian Researches*) has noticed, in the character of Phragmoceras, the form of the aperture and last chamber.

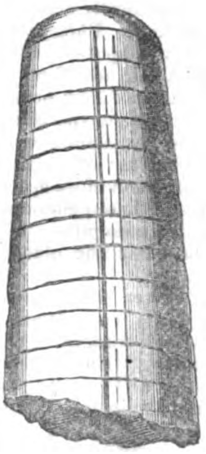
It is difficult to be satisfied, while attempting the arrangement of Nautiloidal Polythalamacea, with following out to its remote consequences any one of these principles exclusively. From the general figure we derive three main groups, viz.:—

A. Orthocerata, &c. Straight.
B. Cyrtocerata, &c. Incurved or convoluted near the apex, ending in a straight or recurved limb.
C. Nautili, &c. Altogether convoluted.

A. To subdivide these groups, we may take in Orthocerata not the septal edge, but the siphuncular structure; and, with Mr. Stokes, separate Ormoceras, because of its tumid interruptal siphuncle; and with Bronn, Actinoceras, because of its radiating siphuncular processes.* Species of Ormoceras belong to the upper Palæozoic strata generally, viz. to the upper Silurian rocks of Murchison, the Devonian and carboniferous systems in Europe and North America, above which they are unknown. Actinocerata have the same or a more limited range. Orthoceratites proper (excluding curved species, like O. paradoxicum, Sow.) have the same geological range, and exhibit so great variation in the form of the cone, the disposition of the septa, and situation of the siphuncle, as to furnish many helps to recognise the otherwise undistinguishable forms of the numerous species which fill the older rocks.

For example, the cone is nearly a circular base, the septa are transverse, and the siphuncle is nearly central in O. giganteum and O. cinctum of the mountain limestone; the cone has an elliptic base, oblique septa, and an excentric siphuncle in O. laterale, O. Breynii of the mountain limestone, and O. imbricatum of the Ludlow rocks.

The last chamber and the mouth also vary in form. In one species from the Ludlow rocks the form of these parts has suggested to Mr. Sowerby the generic name of Gomphoceras (*Silurian Researches*); and another, from the mountain limestone, has received the specific designation O. fusiforme.



Orthoceras laterale.

It may be remarked that the cases are few in which the apex of Orthocerata has been actually observed; in several cases of supposed straight shells, the apicial part is seen to be curved; and it is our conviction that this is very much more common than the heedless application of Orthoceras would lead to suppose.

We have not mentioned in this review the Conulariæ of Miller, as being, though probably of this family, not sufficiently known. The following abbreviated characters may be useful to the geological student:—

Orthoceras (ὀρθός, straight, combined with κέρας, a horn), Breynius, a straight concamerated shell, with septa regularly concave toward the mouth, perforated by a simple nearly cylindrical siphuncle, either in or not far removed from the centre of the disk (never marginal).

α. Last chambers cylindrical, as O. giganteum.
β. Last chamber contracted toward the aperture, as O. fusiforme.

Ormoceras (ὅρμος, a bead, combined with κέρας), Stokes, a straight concamerated shell, with septa as in Orthoceras, perforated by a siphuncle similarly situated, but much dilated in each chamber, and contracted at the parts where the septa are attached to it. The inner part of the siphuncle is divided into chambers, corresponding in number with the chambers, and deeply indented in the middle, where the septa of the shell are attached to them; so that one-half of each division of the siphuncle is in one chamber, and the other half in the next chamber.

The typical species are from Drummond Island, in Lake Huron. (Stokes, in *Geol. Proceedings*, 1838, and *Transactions*, 1840.)

Actinoceras (ἀκτίν, a ray, combined with κέρας), Stokes, a straight conical concamerated shell, with septa as in Orthoceras, and siphuncle shaped, as to its external face, as in Ormoceras. Within the siphuncle is a continuous tube, which appears to have been capable of expansion and contraction, and is furnished with verticillate radii, which connect the tube with the walls of the siphon. (Stokes, in

---

* 'Geological Proceedings,' 1838.

Geol. Proc., 1838, and *Transactions*, 1840; and Bronn, *Lethæa Geogn.*, tab. i., *fig.* 8.)

The species are from Lake Huron and other parts in Northern America, and Castle Espie in Ireland.

(The genus Conoceras of Bronn is included in Actinoceras by Mr. Stokes.)

Conularia, Miller, a straight (or slightly bent?) pyramidal four-sided (concamerated?) shell.

Conularia quadrisulcata is a common shell in what were called transition rocks in Sweden, Wenlock, Dudley, &c.; and a similar if not identical species occurs in the carboniferous rocks of Coalbrook-dale and Rutherglen.

(Sowerby, in the *Mineral Conchology of Great Britain*; and Murchison, in *Silurian Researches*.)

B. In classing the bent or partially convoluted polythalamacea, we may find advantage in attending to the situation of the siphuncle. For example, the siphuncle is subdorsal or approaches the outer line of curvature in Cyrtoceras, Goldfuss, and Gyroceras, Meyer; it is subcentral in Lituites, Breyn; and it is subcentral or approaches the inner line of curvature in the genus Phragmoceras, Broderip.

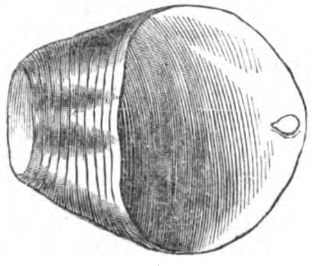
The geological distribution of these forms is nearly as in the Orthocerata. They are all peculiar to the strata below the new red system; and mostly occur below the carboniferous or mountain limestone. Phragmoceras prevails in the Ludlow rocks; Cyrtoceras specially abounds in the strata of South Devon, the Eifel, and the mountain limestone; and Gyroceras and Lituites follow nearly the same rule; a few species of Lituites occur in the Silurian rocks.

We subjoin figures of characteristic forms of Crytoceras, Lituites, and Phragmoceras: of the latter, two figures to show the singular contraction of its aperture.

The brief characters of these generic groups which follow may be sufficient for the recognition of perfect specimens, but such are rarely found in the older rocks, where alone they occur.

Cyrtoceras (κυρτός, curved, and κέρας, a horn), Goldfuss. Bent, arched, or partially convoluted, the free end being sometimes elongated and straight. Septal edges seldom free from a slight waving; siphuncle subdorsal, or even marginal, seldom quite round; aperture nearly orbicular.

Example, Cyrtoceras depressum. From the Eifel.



Cyrtoceras depressum.

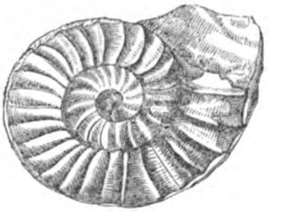
Several other species occur in Devonshire, near Ludlow, &c.

Gyroceras (γυρός, incurved, κέρας, a horn), Meyer. Coiled like a tendril, so that the volutions do not touch. Septal edge even, siphuncle dorsal, marginal. Aperture nearly round.

Gyroceras gracile, Meyer. Bronn, in 'Leth. Geog.,' vol. i., fig. 6. From the states of Dillenburg.

Lituites, Breyn. Convoluted, so that the volutions touch in all the inner part, but afterwards extended into a straight or bent portion. Septa pierced by a subcentral siphuncle. Aperture nearly round.

Example, Lituites articulatus, Sow.



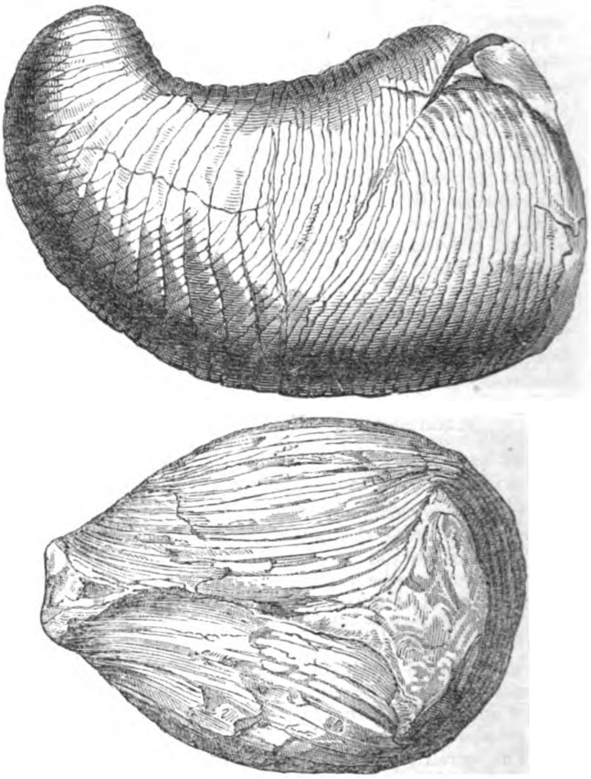
Lituites articulatus.

Phragmoceras (φράγμα, septum, κέρας, a horn), Broderip. Shell incurved and compressed, more or less conical; septal edges entire, crossed externally by the lines of growth; siphuncle near the inner margin; aperture contracted at the middle, its outer extremity produced into an elongated beak.

Example, Phragmoceras ventricosum. Broderip, in 'Silurian Researches.'

C. Among the completely spiral and convoluted Polythalamacea, the situation of the siphuncle and the form of the septa become useful guides.

The siphuncle is dorsal in some Nautili of the mountain limestone, which ought perhaps therefore to be distinguished; subcentral in most of the Nautili of the oolitic, cretaceous, and more recent deposits, as well as in recent species; ventral in Clymenia (Munster) and in some otherwise true Nautili of the coal formation and magnesian limestone.



Phragmoceras veutricosum.

The septa are simply concave, with their edges even, in most Nautili; but in some species (*N. bilobatus*, from the coal formation and mountain limestone) they are deeply undulated, as in the simplest Clymenia [GONIATITES]; in a remarkable fossil from the London clay (*Nautilus ziczac*), deeply and angularly folded, nearly as in some Goniatites. Finally, in the Clymenia of Count Munster, all having a ventral siphuncle, the septal edge is simply waved, or has rounded inflexions, angular bands, or a mixture of these in the same shell.

It is evident from these facts that this part of the classification needs much reconsideration, and that several new genera must be constituted.

The geological distribution of these really convoluted Polythalamacea is interesting and remarkable. The genus Nautilus, as commonly used by English oryctologists, is found in many of the Palæozoic strata, but not in the older ones, in all those of middle age, in the tertiaries, and in the actual ocean. But in the more antient strata, either by a dorsal or a ventral siphon, by peculiarly waved septa, or a discoid figure, the species are widely, and, we believe, generically, disjoined from those of later date. Clymeniæ are only known in a distinct and varied development in strata of the age of certain Devonian and Cornubian rocks, principally at Sth. Petherwin in Cornwall, and in strata believed by Murchison and Sedgwick to be coeval with them, on the flanks of the Fichtelgebirge.

Ammonitidæ.

Following nearly the same plan as that used for the Nautilidæ, we find, from the general figure of these shells, the following divisions:—

A. Baculites, straight.

B. Hamites, Tropæum, Crioceratites, partially convolute, the enlarged end straight.

C. Scaphites, partially convoluted, the free end recurved.

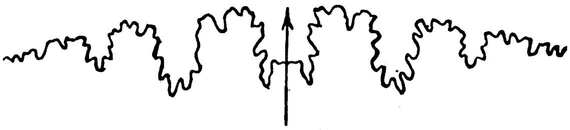
D. Turrilites, spiral round an axis (usually sinistrorsal).

E. Ammonites, Ceratites, Goniatites, convolute or involute.

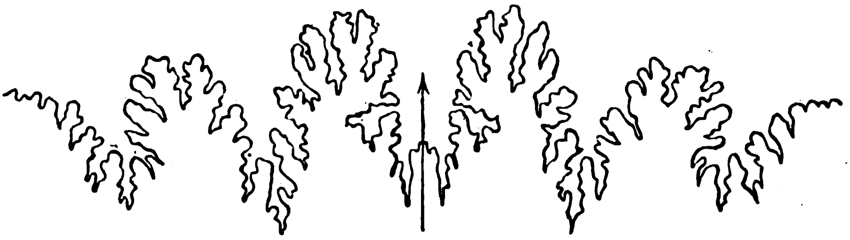
By referring to the article GONIATITES the student may see in what way the subdivision of the only large group of this series (Ammonites, Ceratites, Goniatites, which include many hundred species) may be best effected.

In the article CORNU AMMONIS reference is made to a table of the geological distribution of this group, analysed according to the method of Von Buch.

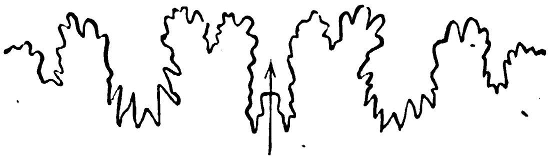
To illustrate this view of the subject we subjoin a few further examples of characteristic Ammonitic sutures, selected from a large series which we prepared a few years since.



Ammonites venustus. (Phillips.) From Speeton clay.



Ammonites sublævis. (Sowerby.) From Kelloway rock.



Ammonites Walcottii. (Sowerby.) From the Lias.

The group A (Baculites) is found chiefly if not wholly in the cretaceous strata (Maastricht, and the chalk of the south of France).

The group B is found in chalk, green-sand, and gault almost wholly (Folkstone, Cambridge, Speeton); but perhaps the species of ammonoidal shells called A. fimbriatus and A. cornucopiæ, from the lias of Yorkshire, should be ranked in the division, as they in fact are, by Mr. Sowerby, under the title of Tropæum. (They are not known to have a straight elongation.)

The group C is very similarly circumstanced, only Scaphites Yoannii being, as far as we know, found in strata below the greensands.

The group D belongs also to the cretaceous rocks.

But the large group E has a prodigious geological range, being found in the whole series of fossilliferous strata from nearly the earliest of the Palæozoic rocks until we arrive at the tertiary series, in which, we believe, no species has really been found, and none have been seen in a recent state. The whole of the Ammonitidæ then have vanished from the oceans, and their way of life is to be inferred from analogy only.

Spirulidæ.

These were partly internal shells (as probably also some of the Ammonitidæ, especially Scaphites, were). Spirula nodosa, Bronn, is certainly not of the genus Spirula, nor is there any reason to admit the occurrence of any of the group below the tertiary strata.

Belemnitidæ.

The genus Actinocamax of Miller, though adopted by Voltz and Blainville, is imaginary, being really only the retral or apicial part of the Belemnite separated from the concamerated portion at a point where nacreous and easily decomposing laminæ prevail, a little behind the apex of the alveolus. This is, we think, quite certain from careful observation of the Belemnites quadratus and other allied forms in the chalk of Northfleet, and Belemnites jaculum of the Speeton clay, the artificial parts of which have been figured as Actinocamaces by Miller and Voltz. Pseudobelus is perhaps differently circumstanced, but its characters are very obscure.

The genus Belemnites is so abundant in the secondary strata of Britain, that at least forty species are possessed by the writer of this article, of which the greater part have not been mentioned in English works on geology. Many other species occur in strata of the same age on the continent of Europe, in India, and in America. It is possible to distinguish by Belemnites alone the leading members of the English and European oolitic and cretaceous systems of strata. Thus, to mention published species only, Belemnites subaduncatus of Voltz, with many allies, is a lias shell; Belemnites Aalensis, also of Voltz, is a shell of the lower oolitic series; Belemnites abbreviatus of Miller, the large variety, is a shell of the middle oolitic series; Belemnites jaculum of Phillips belongs to the Speeton clay; Belemnites Listeri, to the gault and lower chalk ranges: B. quadratus, B. mucronatus, &c., to the chalk generally, or the upper part specially. None have been found in the tertiary series; none have been found below the lias.

Taking then a general view of the distribution of the Polythalamacea noticed in this article, we find—

In a living state . .	Spirulidæ and Nautilidæ.
In the tertiary series .	Some of the Nautilidæ.
In the cretaceous strata	Nautilidæ, Belemnitidæ, Ammonitidæ.
In the oolitic strata .	Nautilidæ, Belemnitidæ, Ammonitidæ.
In the saliferous strata	Nautilidæ (not including Orthocerata), Ammonitidæ (of the type called Ceratites only).
In the carboniferous strata	Nautilidæ, including Cyrtocerata, Orthocerata, Ammonitidæ (of the type called Goniatites only).
In still lower strata .	Nautilidæ (including Cyrtocerata, Phragmocerata, Orthocerata, and Clymeniæ); Ammonitidæ of the type of Goniatites only.

Finally, in strata lower than these, as the Snowdonian slates, where shells and Polypiarian remains occur, none of the Polythalamacea are known.

PO'LYTHEISM (πολύς, much, many, θεός, a god), the doctrine or worship of a plurality of gods. This form of the word is not found in Greek writers. Philo-Judæus conveys the notion by τὸ πολύθεον, and πολύθεος δόξα, and Justin Martyr by πολυθεότης. Philo also speaks of polyarchy (πολυαρχία), with which he contrasts monarchy (μοναρχία), meaning respectively polytheism and the unity of God. St. Athanasius uses πολυθεΐα as the opposite to μοναρχία.

Polytheism differs from idolatry in this respect;—the former refers to a plurality of gods, without including necessarily the notion of *forms*, real or imaginary; the latter refers either to one god only, under some one visible form, or to any number of gods, under as many visible forms.

No one who takes the Bible for his authority will deny that in the earliest ages of mankind the unity of God was implicitly believed. When the idea of a plurality of gods was first entertained, it is impossible to say. The writings of Moses contain no evidence that men were polytheists before the flood; but it is plain that in the time of Moses (B.C. 1500) polytheism prevailed. It is probable that the Chaldæans, of whom Abraham was one, were addicted to polytheism before his time (B.C. 1900); but it is certain that Abraham was not a polytheist. His contemporaries, Melchizedek, king of Salem, and Abimelech, king of the Philistines, both Canaanites, were worshippers of one God, and the God of Abraham himself. The ancient Persians might have been free from polytheism in Abraham's days; but they became first Sabians, or worshippers of the host of heaven, and afterwards Magians, or worshippers of fire. As Magians they held that there are two principles, one the cause of all good, and the other the cause of all evil; the one they represented by darkness, and the other by light; the former, according to Plutarch (*De Isid. et Osir.*, § 46), was called Oromasdes, and the latter Arimanius. [Arimanes.] Among the antient Arabians we find Job and his friends, and Jethro, the contemporary of Moses, worshippers of one God; but yet in the time of Job the worship of the heavenly bodies was practised, as is plainly indicated in *Job*, xxxi., 26, 27. The Ægyptians, in Abraham's days, seem to have had a religion not different from his; but in the time of Moses polytheism had become established among them; for many provisions of his law refer to this fact, and are intended especially to guard the Israelites from imitating the polytheism and idolatry of Ægypt. Cudworth is of opinion (c. 4, § 18) that polytheism originated in Ægypt, but such an assertion is incapable of proof. The Greeks and Romans acknowledged one Being, under the names of Zeus (Ζεύς) and Jupiter, as supreme over all other gods; and they believed further that this one Being was under the absolute power of fate. Yet these inferior beings were worshipped as gods, and the system was essentially polytheistic.

Cudworth has written at great length to show that the antient philosophers in general, though they seem to have been polytheists, were not really such, and that they worshipped mentally one Supreme Being under different names. But however this might be, the popular notions were not so refined. Wherever the philosophers have appeared to be polytheists, the people have been polytheists in reality; and, as Philo-Judæus says (*De Ebrietate*), 'Polytheism in the minds of the ignorant is atheism.'

The progress of polytheism seems to have been, or might have been, something like the following:—men looked upon the sun and the moon, and the whole of the heavenly bodies, with fire, water, earth, and air, as, in some way or other, representing the Deity. Then they gradually substituted the representatives for the Deity himself, and paid adoration to them. Next, in wishing to preserve the memory of departed heroes or great men under the form of pillars or images, they fell into the practice of deifying or worshipping them. Then they regarded certain of the brute creation, as either serviceable and so to be reverenced, or noxious and so to be dreaded, and they converted them into gods. Thus it was also with respect to mountains, rivers, and other inanimate objects. And this was not all: they devised a multitude of rites in honour of their respective gods, some of which were of a most debasing character.

Wherever the Christian religion has been established, polytheism and its attendant evils have disappeared; but there still remain vast portions of the world in which polytheism prevails; and the miseries are inconceivably great which millions of the human race are still voluntarily inflicting upon themselves with a view to propitiate the favour of imaginary deities.

(Cudworth's *Intellectual System*; Henry More's *Mystery of Godliness*; Shuckford's *Connection of Sacred and Profane History*.)

POLYTRE'MA, a genus of Milleporidæ.

POLY'TROPA, Mr. Swainson's name for a genus of *Muricidæ*, placed by him under his second subfamily *Scolyminæ*, with the following

Generic Character.—Bucciniform; but the base narrowed, and ending in a straight and contracted but rather short channel; spire longer, or as long as the aperture; exterior folliculated or tuberculated; inner lip flattened, as in *Purpura*; basal notch small, oblique; no internal channel.

Example, *Polytropa crispata*. (*En. Méth.*, 419, f. 2.)

POMA'CEÆ. [Rosaceæ.]

POMATORHI'NUS. [Merulidæ, vol. xv., p. 123.]

POMBAL, MARQUIS DE. DOM SEBASTIAO JOSE' DE CARVALHO, Count d'Oeyras and Marquis de Pombal, was one of the most able public men that have ever appeared, and certainly the only distinguished statesman that has ever presided over the councils of the Portuguese nation. He was born in 1699, at Soura, a village in the territory of Coimbra, of an old and noble family, though not of the first class. Having completed his early studies in his native village, he was sent to the university of Coimbra for the purpose of studying for the bar. Young Carvalho followed a course of lectures; but the quiet pursuits of the law being incompatible with the vivacity or rather the turbulence of his character, he adopted the profession of arms. But this profession did not prove more agreeable to him than that which he had relinquished. Various causes for his leaving his regiment have been conjectured. What may be the true reason we have no means of deciding; but it is certain that he quitted the corps in which he served, and led a private life till 1739, when, through the influence which his uncle Paulo Carvalho had with Cardinal Motta, a person much in favour with John V., he was appointed extraordinary envoy to the court of London; and afterwards to Vienna, as mediator between the empress Maria Theresa and the Pope, to settle the disputes which had arisen in consequence of the suppression of the archbishopric of Aquileia.

Whilst in that capital, Carvalho had the good fortune to marry a lady of high rank and influence, the Countess Daun, niece of the General of the same name who figures so prominently in the wars of the empress Maria Theresa with Frederick the Great of Prussia. On his return, the queen of John V., who was an Austrian princess, became so much attached to her countrywoman, the lady of Carvalho, that for her sake she prevailed on her son, immediately after the decease of her husband, to raise him to power, in consequence of which Carvalho was entrusted by Joseph I. with the direction of foreign affairs.

Elevated to this high station, Carvalho began to display his great administrative talents. His admirers have gone so far as to compare him with Richelieu; while his enemies, unable to deny the merit of his administrative conduct, have attributed it to ignoble and selfish motives. But both these extremes are equally distant from justice and truth. Carvalho may have been as profound a politician as Richelieu, but the political relations and rank of such a kingdom as Portugal could not and did not offer him a sphere in which to display them; but in the internal and economical administration of the kingdom, in discernment, activity, and legislative abilities, he has no superior. After his promotion, which took place in 1750, Portugal may be said to have been regenerated. He favoured the establishment of several manufactures, and encouraged the art of printing and agriculture; he introduced into the university of Coimbra a system of studies which substituted, for the mere study of the classics and antient languages, the cultivation of the physical and mathematical sciences; he furnished the university with a chemical laboratory, a botanic garden, and an observatory; he introduced into Brazil the cultivation of coffee, sugar, cotton, rice, indigo, and cocoa; he created the companies of Pernambuco, Para, and Maranhao, and established so strict a police in the kingdom, that even idlers and loungers were not allowed to promenade the streets.

With all his great qualities, which command our esteem and admiration, he was detested both at home and abroad. Those who hitherto had lived and enriched themselves by the abuses that had crept into the various branches of administration, as well as those who suffered from the severity of his ordinances, were his declared enemies. He checked the obnoxious power of the Inquisition, and banished the Jesuits from the Portuguese dominions. Whatever might be the policy of the latter measure, it was carried into effect with great inhumanity. [Jesuits, p. 112.] His interference with the monopoly which foreign merchants had acquired in the commerce of Portugal rendered him an object of detestation to foreigners, and particularly the English; still all his measures had for their object the prosperity of the country, which he effectually promoted, so far as to place Portugal on a level with other European states.

The Marquis of Pombal however is not without reproach. His unremitting persecution of the nobility, and his merciless conduct towards the family of the Tavoras and every individual whom he suspected of having had any part in the attempt made against the life of the king, dimmed the brilliancy of his career. It is asserted by some that he conceived a great dislike against the nobility from the time of his first marriage. His first wife, Dona Theresa de Noronha Almada, belonged to one of the most antient families of Portugal, and was the daughter of the only heiress of the Almadas; while he was nothing, and had no other recommendation than a handsome figure, and the power which superior intelligence invariably gives. Her relatives accordingly made the strongest opposition to the marriage with Carvalho, to which circumstance is attributed his hatred of that class.

On the death of Joseph I., the queen, who considered that Carvalho had occupied that place in the affections of the king which she alone ought to have filled, and had likewise taken a dislike to him on account of his persecution of the nobility and the Jesuits, ordered him to retire to Pombal, where he died in the eighty-first year of his age. The finest parts of Lisbon still bear testimony to the value of his administration, for they were built according to his designs after the earthquake. He was created Count d'Oeyras in 1759, as a testimony of the royal regard for the zeal which he displayed when the attempt was made to shoot the king Joseph I.; and on his effecting a reconciliation with the pope at a much later period, his grateful master created him Marquis de Pombal. Although he is accused of enriching himself by means unworthy of his rank, no person who is acquainted with his private habits, with the method which he had adopted to make his property valuable, and with his general system of economy, can doubt of his integrity. When he retired from the ministry, he left about forty-eight millions of cruzados in the public treasury, and thirty in the *caixa de decimos*, a surplus which the government of Portugal had never had before.

(*Recordaçoes de Jacomo Ratton*; *Memoirs of the Marquis of Pombal*; Chalmers's *Biographical Dictionary*; *Biographie Universelle*.)

POME, in botanical language, signifies a fleshy inferior many-celled fruit, such as that of the apple, pear, &c. It differs from a berry in its seed not being buried in pulp.

POMEGRANATE. [PUNICA.]

POMERANIA (in German, *Pommern*), one of the eight provinces of the Prussian monarchy, is situated between 52° and 54° N. lat. and 12° 30′ and 18° E. long. It is bounded on the north by the Baltic, on the east by West Prussia, on the south by Brandenburg, and on the west by Mecklenburg. It is a long tract of coast, extending 200 miles on the Baltic, and varying in breadth from thirty to sixty, and, in some places, to eighty miles. The area is 12,000 square miles, and it is divided into the three governments of Coeslin, Stettin, and Stralsund.

Pomerania is one of the lowest and flattest countries in Germany; only a few hills of moderate height break this continuous level: of these hills, the Gollenberg, between Cöslin and Zunow, which is the highest, has scarcely an elevation of 300 feet. The soil consists of sand; and, along the coast, of sea-sand, which former inundations and repeated storms have spread over the country. The coasts of that part formerly called Further Pomerania are protected against the sea by sand-hills and dikes. Here and there this sand is mixed with clay, or passes into a black fertile loam, especially in the government of Stralsund. The island of Rügen, which belongs to this government, has very broken coasts, but the heaviest and best soil of all Pomerania.

The province is crossed in its broadest part by the Oder, which, flowing through a marshy tract, divides into many arms or channels, one of which, the Great Regelitz, forms, towards its mouth, the great Dammer Lake, and, together with the main stream, falls into the extensive inland water the Frische Haff, the eastern part of which is called the Great Haff, and the western the Little Haff. The water of the Haff is fresh, and it is only during the prevalence of the north wind that it is rather brackish, and considerably higher, owing to the influx of the sea. The two great islands of Usedom and Wollin separate it from the Baltic, with which it is connected by three outlets: on the east by the Divenow, which falls into the sea between Wollin and the continent, after forming a great lake called the Kaminsche Boden; in the middle by the Swine, between Wollin and Usedom; and on the west by the Peene, between Usedom and the continent. These three outlets might be called the mouths of the Oder. The Ucker from Brandenburg, and the Peene from Mecklenburg, both navigable streams, fall into the Frische Haff. The Ihna flows into the Dammer Lake. Most of the other rivers fall, after a short course, into the Baltic. There are many small lakes: that of Madine, which is celebrated for its lampreys, is one of the largest. The navigation on the Pomeranian coast is dangerous, owing to the want of harbours, there being only three safe ones, Stralsund, Swinemunde, and Colberg.

The climate of Pomerania is cold, and the weather is changeable: storms on the coast are not uncommon. The natural productions of the country are:—1, horses, horned cattle, sheep, goats, swine, small game, domestic poultry (especially geese), sea and river fish, and bees; 2, corn, peas and beans, potatoes, fruit, timber, flax, and tobacco; 3, alum, bog-iron, salt, turf, and amber. The soil in some parts is so indifferent, and the climate so unfavourable, that agriculture is in a very backward state; and notwithstanding the industry of the inhabitants, no great improvement can be effected. The Pomeranian however has done everything that is possible, and many parts are admirably cultivated. The country produces more corn than is required for home consumption. Sufficient flax is grown for the use of the inhabitants; and fruit is so abundant, that large quantities, especially of apples, are exported. The breeding of horned cattle is carried on to a great extent; the flocks of sheep are numerous on the great estates; and all the country-people keep numbers of swine. The breeding of poultry is very profitable: immense flocks of geese are kept, the quills, feathers, and smoked breasts of which (celebrated in all Germany and the north of Europe by the name of Pommernsche Spickgänse) are most important articles of exportation. The Pomeranian forests are very extensive and productive. The fisheries likewise yield a considerable profit; but the sea-fishing is not carried on to the extent that it might be. Of fresh-water fish, large quantities, both fresh and smoked, are exported. The mineral kingdom is poor. Some bog-iron ore is smelted at Torgelow; there are salt-works at Colberg; and some amber is procured, especially near Stolpe. The most important article is turf, of which about sixteen million sods (bricks, as they are called) are annually dug. There are no manufactures of much importance; good and strong linen however is made, and is a considerable article of exportation. What manufactures there are, are confined to the principal towns. [STARGARD; STETTIN; STRALSUND.] The trade of this province is very important; it is carried on partly by sea, partly on the Oder, and partly by land, with the neighbouring provinces. The exports include all the natural productions of the country; the imports are colonial articles, some manufactured goods, and there is also a great transit trade to and from the provinces on the Oder, especially Brandenburg and Silesia.

The inhabitants are by descent partly Sclavonians and partly Germans. German peasants were brought into the country in the twelfth century, especially by the monasteries, and the dukes founded German towns and villages, to which they granted great privileges. Hence the Germans in process of time outnumbered the antient race. Genuine Sclavonian blood is now only to be met with in the north-eastern corner of the province, where these people preserve their own dialect of the Sclavonic language, and still differ in manners and customs from their German fellow-countrymen. The nobles are numerous, chiefly consisting of German families who have settled here since the twelfth century, and possess several important privileges, though they have been much abridged of late years. The vassalage of the peasants was abolished by the late king Frederick William III. The population, according to Dieterici (1838), was 941,193, that is, on an average, 1660 to one German or twenty-one English square miles. A remarkable increase has taken place in the government of Cöslin, where, in 1815, there were only 900 persons on a German square mile, and in 1838, 1300. The great majority of the inhabitants are Lutherans: there are a few French and German Calvinists, about 7000 Roman Catholics, and 4200 Jews. On the 15th of June, 1824, the 700th anniversary of the introduction of Christianity into Pomerania was celebrated with great solemnity in the whole province.

Pomerania was formerly a considerable part of the antient kingdom of the Wends, or Vandals. From the year 1062 it had its own dukes, of whom Boleslaus X., or the Great, is one of the most distinguished. The Christian religion was introduced in the twelfth century; the first Pomeranian converts were baptised on the 15th of June, 1124, by Otto (Otho), bishop of Bamberg, at a place called Ottobrunn (Otto's Well). The line of the dukes became extinct on the death of Boleslaus XIII., in 1637. The last female descendant of the Pomeranian dukes was married to a Prince Croy, after whose death she returned to Pomerania, where she died, on the 19th July, 1660, having instituted a festival to be kept every ten years in memory of the line of princes which became extinct in her person. On the death of the last duke of Pomerania, the electoral House of Brandenburg, conformably to a family compact, should have taken possession of the whole country; but Pomerania having been occupied by the Swedes during the Thirty Years' war, Prussia was obliged to be content, at the peace of Westphalia, with Further Pomerania (to the east of the Oder), leaving Sweden in possession of Hither Pomerania, with the island of Rügen. Charles XII. of Sweden was however obliged to cede, by the treaty of Stockholm in 1720, the southern part of Pomerania and the islands of Usedom and Wollin to Frederick William I., king of Prussia. Lastly, by a convention concluded on the 4th of June, 1815, Prussia obtained possession of the whole of Swedish Pomerania, which Sweden had ceded to Denmark as a compensation for Norway. In exchange, Prussia gave to Denmark—1, the duchy of Lauenburg, which it had obtained from Hanover in exchange for East Friesland; 2, a sum of two millions of dollars, paying also 600,000 Swedish dollars which Denmark owed to Sweden; 3, it indemnified the Swedish holders of dotations in this province to the amount of 43,000 dollars annually; 4, it paid to Sweden 3,500,000 dollars: so that Prussia gave for this province the duchy of Lauenburg, 5,500,000 Prussian dollars, 600,000 Swedish dollars, and the indemnity to the Swedish holders of dotations. It is worthy of remark, that the sum of three millions and a half of dollars paid by Prussia to Sweden for a province of which Sweden had been in possession two centuries, was claimed by the present king of Sweden (Bernadotte) as belonging to himself. Of this sum he applied two millions to the service of the state, as an especial favour, and put the remaining million and a half into his own pocket.

POMFRET, JOHN, was born in 1667, at Luton in Bedfordshire. He studied at Queen's College, Cambridge, where he was admitted to a Bachelor's degree in 1684, and to a Master's in 1698. Having entered into orders, he obtained the rectory of Maldon in Bedfordshire. In 1703 he came to London with the prospect of obtaining further preferment, but found Bishop Compton strongly prejudiced against him on account of some lines in 'The Choice,' which seemed to imply that a mistress was to be preferred to a wife; and before Pomfret, who was now married, could remove the bishop's objections, he was attacked by the small-pox, which carried him off in 1703, in his thirty-sixth year.

He published his poems in 1699, and some additional poems were published after his death by an anonymous friend. His poems had once many readers, especially 'The Choice,' in which he describes how he would live if he had a moderate independence—what would be his choice of a house and garden, of wines, of books, of friends, and of a female friend, for he 'would have no wife.' Dr. Johnson says that 'he has been always a favourite with that class of readers who, without vanity or criticism, seek only their own amusement.' We doubt if any class of readers now exists who could find amusement in reading such poems as those of Pomfret. They are deservedly neglected.

(Johnson's *Lives of the Poets.*)

POMMERN. [POMERANIA.]

POMŒ'RIUM, or, as it is written in inscriptions, POMERIUM. The Pomœrium, according to Livy (i. 44), was a consecrated spot on each side of the wall of the city of Rome. This spot was consecrated by the Eutruscan ceremonies of inauguration; and whenever the city was enlarged, the Pomœrium was also extended. The space within the wall might not be built upon, and the space without might not be tilled.

This definition of the Pomœrium is true only where the Pomœrium coincides with the real wall; since during the later times of the kings, and subsequently, the Pomœrium was not the same as the wall. The Pomœrium included that part of the city which was consecrated by Etruscan auspices, which belonged exclusively to the patricians; and thus the Aventine, which was inhabited by the plebeians, was never included within the Pomœrium till the reign of the emperor Claudius (Aul. Gell., xiii. 14), although it had long before that time formed part of the city. The Pomœrium of Romulus, which is traced by Tacitus (*Ann.*, xii. 24), included only the Palatine. The Quirinal hill is said to have been added by Numa (Dionys., *Ant. Rom.*, ii. 62), and the Cælian by Tullus Hostilius, to the boundaries of the city, by which is probably meant that they were included within the Pomœrium, or consecrated part of the city, since the actual fortifications were not completed till the time of Servius Tullius. The Quirinal and Viminal hills were added to the Pomœrium by Servius Tullius (Liv., i. 44), and the Aventine, as already stated, by the emperor Claudius.

We learn from Tacitus (*Ann.*, xii. 23) and Aulus Gellius (xiii. 14) that those persons only were allowed to extend the pomœrium who had enlarged the limits of the empire. Tacitus adds that no one had used this privilege from the time of the kings to that of Claudius, except Sulla and the emperor Augustus. Other writers however say that it was done by Julius Cæsar.

(Aul. Gell., xiii. 14; Dion Cass., xliii. 50; Cic., *Ep. ad Att.*, xiii. 20, 33, 35.)

POMO'NA, or MAINLAND. [ORKNEYS.]

POMPADOUR, MADAME DE. [LOUIS XV.]

POMPE'I, GIRO'LAMO, born at Verona in 1731, of a patrician family, applied himself chiefly to the study of the Greek and Latin writers, and became a good Hellenist. His translation of the 'Lives' of Plutarch is by far the best in the Italian language, and has gone through more than ten editions. In 1785 Pompei was offered a chair in the university of Pavia, which he declined, out of attachment to his native town. He was intimate with Maffei, Torelli, Rosa Morando, and other learned men of Verona, and he was preceptor to Ippolito Pindemonte, and also to two accomplished ladies of the same town, Elisabetta Mosconi and Silvia Curtoni Verza. Pompei died at Verona in 1788. His other works consist of 'Canzoni Pastorali,' which are much esteemed, and other Italian poetry, including some translations from the Greek, and of several dissertations. His biography has been written by his disciple Pindemonte, and by Cardinal Fontana, 'De Vita et Scriptis Hieronymi Pompei.'

POMPEII, an antient town of Campania, situated about thirteen miles south-east of Naples, in a plain at the foot of Vesuvius, through which runs the little river Sarno. The town appears to have been once close to the sea, but is now nearly two miles from it, in consequence of the physical changes which have taken place in this district. It stood on an eminence formed by a bed of lava, which seems to have been thrown up from the ground in this spot, and in several other places round the foot of Vesuvius, long before any of the eruptions recorded in history. Pompeii, as well as the neighbouring town of Herculanium, is said by Strabo (p. 247) to have been originally possessed by the Osci, and then by the Tyrseni and Pelasgi. It afterwards fell under the power of the Greek colonies of Cumæ and Parthenope, and lastly of the Samnites (about 440 B.C.), who made themselves masters of this coast as far as the river Silarus. About eighty years later the inhabitants of Campania threw off the yoke of the Samnites, and placed themselves under the protection of Rome. In the second Punic war the Campanians joined Hannibal, but were severely punished for it by the Romans, who brought the country under subjection. Pompeii however is not mentioned among the towns hostile to Rome. In the Social War (90 B.C.) the Campanian towns revolted, and Pompeii, among them, joined the Marsian Confederacy. At the end of that war several of those towns were severely chastised by the Romans. Stabiæ, which stood within four or five miles south by east of Pompeii, was entirely destroyed, but Pompeii appears to have been spared. Nothing more of any importance is recorded of Pompeii, except a quarrel between the inhabitants and those of Nuceria on the occasion of a gladiatorial fight in the amphitheatre of Pompeii, which many of the Nucerians had come to witness. The affair was brought before the emperor Nero, who adjudged that the Pompeians should be deprived of all theatrical amusements for ten years, a punishment which was considered very severe in those times. Four years after this a fearful earthquake threw down a great part of Pompeii, A.D. 63. The following year, while Nero was singing at Naples, another earthquake occurred. At last, in the year A.D. 79, in the month of August, the first recorded eruption of Vesuvius took place, which is well known from the letter of Pliny the Younger, whose uncle lost his life on the occasion. [Plinius.]

In this eruption both Herculanium and Pompeii were buried; the former under a mass of lava, Pompeii under showers of stones, cinders, and ashes. The ceilings and upper stories of the houses, being chiefly of wood, were either burnt by the red-hot stones and cinders ejected from Vesuvius, or were broken down by the weight of matter collected on the roofs. The catastrophe was not so sudden but that most of the inhabitants had time to escape with their moveable property: indeed it would appear that the town was not altogether buried in one eruption, but that this was the work of several consecutive eruptions, between which the inhabitants had time to come and revisit their half-ruined habitations and recover some of their property. Successive layers of volcanic matter are clearly traced, and the lowest has evidently been moved, but the others are untouched. A bed of soil at last formed itself all over the town, filling up the vacant spaces between the buildings, grass grew upon it, corn was sown, and the vine was planted in the fields thus formed above the ruins of Pompeii, whose existence was forgotten until 1689, when the first indications of ruins protruding above the ground were noticed. In 1755 the excavations began. They have been interrupted and resumed at various times, and the result has been that about a fourth part of the city along the western side of the walls has been excavated and cleared of the rubbish. This portion, which appears to have been the finest part of the town, contains about eighty houses and numerous small shops, two theatres, two basilicæ, eight temples, the forum, the amphitheatre, the baths, the prison, and other public buildings of less note. The city was antiently surrounded by walls, of which the greater portion has been traced, including six gates and twelve towers. The circuit of the walls is nearly two miles, and the area within measures about one hundred and sixty-one acres. There were however suburbs, one of which, at the north-western or Herculanium gate, is partly excavated, and is called the street of tombs, from a number of handsome tombs which line the road leading to the town. The suburban villa, called the villa of Diomedes, is in this quarter. On entering the gate the visitor finds himself in a long tortuous street leading to the forum. To the left of this street is the house called that of Sallust, which occupies a square of about forty yards; and near it is the house of Pansa, which, with its court and garden, is about one hundred yards long by forty wide. These are the two finest private houses yet excavated, and they afford a good specimen of the interior arrangement of the dwelling-houses of the antient Romans. [Atrium.] Nearer to the forum are the baths, in very good preservation, which appear to have been finished a short time before the destruction of the town. A description of them is given under Baths.

Upon entering the forum the spectator finds himself in a large oblong area, about one hundred and twenty yards long and forty wide, surrounded by columns, pedestals which once supported statues, the ruins of temples, triumphal arches, and other public buildings. Around the west, south, and east sides there runs a Grecian Doric colonnade, some of the columns of which are standing; they are two feet three inches in diameter, and twelve feet in height; the interval between them is six feet ten inches. At the north end of the forum stand the ruins of a building, which has been called the temple of Jupiter, 120 feet long and 43 feet wide: when entire, it must have been 60 feet high. The columns are of the Corinthian order, and three feet eight inches in diameter. On the west side of the forum is the temple of Venus, which stood in an open area surrounded by a wall and portico. Beyond it, to the south, is the basilica, or court of justice, the largest building in Pompeii, 220 feet long and 80 wide: the lateral walls remain, but the roof and upper gallery have fallen in. On the opposite or eastern side of the forum is a building which was erected by a woman of the name of Eumachia, apparently as a place of assembly for men in business, and especially for the cloth scourers, who constituted a considerable body at Pompeii. It consists of a large area 130 feet by 65, surrounded by a double gallery, and having a portico in front. On the same side of the forum, but towards its northern end, is the Pantheon, so called from twelve pedestals placed in a circle round an altar in the centre of an extensive area, on one side of which are cells for the priests, and on the other side is an adicula, the walls of which are covered with beautiful fresco paintings, the colours of which still retain all their vividness.

The other public buildings of Pompeii which have been excavated are the two theatres, the larger of which is capable of containing about 5000 persons; the temple of Hercules, which is the oldest building in the town, and the amphitheatre. The latter, which is at the eastern extremity of the town, separate from the other excavated parts of the town, is 430 feet long and 335 feet broad. It resembles in its structure the other buildings of the same class, which are described under Amphitheatre.

For a description of these buildings the reader is referred to the work entitled 'Pompeii,' in the *Library of Entertaining Knowledge*, published under the superintendence of the Useful Knowledge Society, and to the elaborate works of Mazois, Sir William Gell, and Donaldson.

The greater part of the private dwellings are small and mean, for the inhabitants lived mostly out of doors, and reserved all their magnificence for the public buildings. The numerous statues, medals, and other moveable antiquities found at Pompeii have been deposited in the Royal Museum of Naples, and are described in the work entitled 'Museo Borbonico,' published at Naples.

POMPEIUS, CNEIUS, commonly called Pompey, was born on the 30th of September, 106 B.C., in the consulship of C. Attilius Serranus and Q. Servilius Cæpio, a few months after the birth of Cicero. He was six years older than Cæsar. His family was plebeian, and one of his ancestors was said to have been a flute-player. His father, Pompeius Strabo, however, joined the aristocratic party, and fought under their banner in the Marsic war, but, being a man of extreme selfishness, he was in reality faithful to no party, and at last made himself so notorious for his avarice and cruelty, that, after he had been killed by a flash of lightning, the people at his funeral tore the body from the bier and dragged it through the streets of Rome. (Plut., *Pomp.*, i.; Vell. Pat., ii. 21.)

Respecting the early education of Pompey nothing is known, and the first time we find his name mentioned is in 89 B.C., in the Marsic war, when he accompanied his father to fight against the Italians; he was also in the battle at the gates of Rome between his father and Cinna and Sertorius. Soon after this battle, Cinna caused money to be distributed among the soldiers of Pompeius Strabo, and bribed a friend and comrade of Pompey to murder him and his father; but the courage of the young man saved his own and his father's life, and put down an insurrection among the discontented soldiers. His father died soon after this event, and when the Marian party gained the upper hand, and made their entrance into the city, the house of Pompey was plundered. It was not until after the death of Marius, in 86 B.C., that he ventured to appear again in public, when his enemies immediately charged him with being the accomplice of his father in the plunder of Asculum. Having no confidence either in the justice of his cause or the eloquence of his advocates L. Martius Philippus and Q. Hortensius, he secretly betrothed himself to the daughter of P. Antistius, who was to preside at the trial, by which means, together with the protection of Carbo, he was acquitted.

When Sulla was returning from his expedition against Mithridates, Pompey, who had fled from the camp of Cinna just before he was murdered, was in Picenum, where he possessed very extensive estates and great influence. (Vell. Pat., ii. 29.) Here he was engaged in raising at his own expense an army, with which he hoped to overcome the Marian party before the arrival of Sulla, and thus to gain immortal fame. Without the authority or sanction of the Roman senate he organised three legions, consisting chiefly of the veterans of his father. Three generals of the Marian party surrounded him in three different camps, and their imprudent conduct enabled him to attain his object. He directed his main force against one of them, M. Brutus, and defeated his cavalry, which in its flight threw the infantry into disorder; the two other generals, discouraged by the failure of their colleague, retreated. Pompey was received in all the towns of Picenum as their deliverer. (Plut., *Pomp.*, 7.) The senate was indignant at his arbitrary proceedings, but his army remained faithful to him. At the interview which he afterwards had with Sulla, for whose cause he had so successfully exerted himself, he displayed enough of his vain and ambitious character for Sulla to discover that Pompey wished to be looked upon as a man of no less importance than himself. When therefore Pompey, with apparent humility, saluted him as imperator, Sulla returned the compliment. Thus Pompey's wishes were gratified, and the impression made upon his soldiers, who now began to look upon him, a young man of twenty-three years of age (Vell. Pat., ii. 29, 1), as their legitimate general, was highly favourable. But not being recognised by the senate, and not fighting under the auspices of Sulla, he was in reality nothing but the leader of an armed band of adventurers.

Sulla was made dictator, and the civil war was carried on in Italy with unremitting vigour. While the consul C. Marius the Younger was besieged in Præneste (82 B.C.), his colleague Cn. Carbo fought an indecisive battle against Sulla at Clusium, but his legates Marcius and Carrinas were defeated by Pompey. Carbo then retreated to Ariminum, and sent Marcius to the relief of Præneste, but Pompey repelled him in the Apennines with great loss. Carbo himself in despair sailed to Africa, but his troops, which remained in Etruria, were closely watched and afterwards dispersed by Pompey, whereby the fall of Præneste was prepared. Sulla, partly to reward the young champion of his party, partly to make himself sure of his attachment, presented him with the hand of his step-daughter Æmilia, who was pregnant by Manius Glabrio, from whom she was obliged to separate. (Plut., *Sulla*, 33; *Pomp.*, 9.) Pompey, who was married to Antistia, abandoned her, but Æmilia soon afterwards died in childbed. Pompey was thus a declared champion of the party of Sulla, and after the war in Italy was brought to a conclusion, he undertook to punish the remaining enemies of the aristocracy in Sicily, Africa, and Spain. Carbo attempted to escape to Egypt, but was overtaken and brought in chains before Pompey, at Lilybœum; his companions were put to death without even the form of a trial; Carbo, though he had once shown himself a friend to Pompey, was solemnly condemned to death, and Pompey sent his head to Sulla. All Sicily submitted to him without any further resistance. Much has been said about his moderation in this island, but he only spared those whom it would have been useless to destroy. Leaving the administration of Sicily in the hands of Memmius, his brother-in-law, he set out for Africa with an immense fleet to oppose Domitius Ahenobarbus, under whom some remnants of the Marian party had assembled, and also to support Hiempsal, a friend of Sulla, against Hiarbas, king of Numidia. A battle ensued, in which Pompey, though with great loss, gained a victory. Domitius fell, Hiarbas was put to death, and Hiempsal restored to his throne. The whole object of this campaign was attained in the course of a few months, and Pompey gained general admiration for his disinterestedness. He returned to Rome, where thousands came out to meet and gaze at the young hero. Sulla himself complimented him with the appellation of Magnus (the great), which henceforth became hereditary in his family. The time at which he received this surname is differently stated by different authors, but from the examination of the various accounts in Drumann's 'Hist. of Rome' (vol. iv., p. 335, &c.), it cannot be doubted that he obtained it after his African expedition. But the vanity of Pompey was not satisfied with these distinctions, and although he had not yet held any public office, and was only a knight (eques), he was bent upon entering Rome in triumph. Several discussions took place in the senate, where great efforts were made to prevent such an unprecedented occurrence, and when at length Pompey had recourse to threats, saying that the people would prefer the rising to the setting sun, Sulla, indignant at his arrogance, exclaimed, 'Well, let him triumph.' Pompey thus entered Rome in triumph. After this display of childish vanity Sulla treated him with a coldness which did not fall much short of contempt. (Plut., *Pomp.*, 15.)

This feature of vanity in his character explains the otherwise unaccountable fact that, in opposition to Sulla, he exerted all his influence to secure the consulship for Æmilius Lepidus. Sulla, foreseeing the consequences, said to Pompey, on this occasion, 'Thou hast given the sword into the hands of thy own enemy.' Sulla soon after died (78 B.C.), and Lepidus openly made the impotent attempt to rescind all the laws of the late dictator, in which he hoped to be supported by Pompey; but Pompey, remaining faithful to his party, saved the aristocracy. It was only owing to the great precautions taken by the senate that peace and order were maintained during the consulship of Lepidus and Q. Catulus; but after the expiration of the year, when Lepidus had gone to his province of Gaul, the war broke out. Lepidus was defeated by the united forces of his late colleague Catulus and Pompey, and the latter was now commanded by the senate to take the field against M. Junius Brutus, the father of the celebrated Brutus, who was still at the head of a division of the army of Lepidus in Cisalpine Gaul. Brutus defended himself bravely in Mutina, until at length either an insurrection among his soldiers or hunger compelled him to surrender: he obtained the promise of safe passage, but was put to death the next day by Geminius, at the command of Pompey. (Plut., *Pomp.*, 16, 64; *Brut.*, 4.) Scipio Æmilianus, the son of Lepidus, was made prisoner in Liguria, and likewise put to death at the command of Pompey. Lepidus was at length attacked by Catulus and Pompey, in the neighbourhood of Cosa, and being again defeated, he resolved, with the remnant of his army, to seek refuge in Sardinia, but he was repelled from the island by the Roman governor, and soon after died. The surviving followers were treated with great clemency, partly that they might not be induced to join the army of Sertorius in Spain, and partly because the victorious party themselves wished for peace in order to enjoy the fruits of their victory. Pompey also received orders to lay down his arms and return to Rome. He disobeyed the command under various pretexts; but the truth was, he was anxious to obtain the command against Sertorius. And when indeed the power of Sertorius assumed a more threatening character, when Perperna had joined his army, and the senate saw no one else that could be entrusted with the command against so formidable an enemy, it was at length reluctantly decreed that Pompey should be sent to Spain with the power of a proconsul, and in 40 days he was ready for departure, with an army of 30,000 foot and 1000 horse. He left Italy in 76 B.C., when he was thirty years of age. He crossed the Alps, according to Appian (*Civil.*, i. 109), between the rivers Rhône and Po, and directed his course towards the southern coast of Spain. Several Spanish tribes, and even Lauron, when besieged by his adversaries, declared for him. In the ensuing campaign Metellus defeated Perperna, and took his camp, but Sertorius wounded Pompey with his own spear, and compelled him to retreat. Not long after, a great battle was fought near Seguntia, in which Pompey was again defeated, and 6000 of his men were slain. In this way the war was carried on with various success for nearly four years; and had not Sertorius been betrayed by the Spaniards, and at last assassinated by conspirators headed by Perperna (74 B.C.), he would probably have driven the Romans from Spain, although Pompey conducted the war with great skill. He now also received reinforcements from Italy, where his demands were readily granted by the senate, and strongly supported by the consul Lucullus, who feared lest Pompey might return, as he had threatened to do, and obtain the command against Mithridates. Pompey advanced in Spain as far west as Cale (Porto).

After the death of Sertorius, Perperna was at the head of his armies; but as he had never distinguished himself as a general, he secured no confidence. He was undecided whether he should offer battle to Pompey, until he was emboldened by the appearance of a small division of the enemy's army, but he soon found himself attacked by the whole hostile forces, and took to flight. He was found in a wood; and, in order to save his life, offered to deliver up to Pompey letters of Roman nobles, in which they had invited Sertorius to Italy, and expressed their aversion to the constitution of Sulla. Pompey refused to see him, and ordered him to be put to death, and the papers to be burned without being read. The army of Perperna dispersed; but those who could not expect a pardon sought refuge in those towns which were determined to defend their liberty to the last. Some of these towns were razed to the ground by Pompey, while some distinguished Spaniards, who had supported the enemy of their own country, were individually rewarded with the Roman franchise. (Cic., *Pro C. Balbo*, 8.) As Metellus left Spain before Pompey, the latter availed himself of this opportunity to make it appear that he alone had accomplished the pacification of Spain, and, with the assistance of commissioners sent by the senate, he proceeded to organise the administration of the province of Spain. The apparent success with which his undertaking had been crowned increased his vanity and the admiration of the multitude, who took him for what he wished to appear, and longed to see him return to Italy, where another great object was to be accomplished. Almost the whole of southern Italy was in the hands of the revolted slaves under Spartacus. On his return, Pompey erected in the Pyrenees, on the road to Gaul, a pillar, with an inscription recording his victories. (Strabo, iii., 4, p. 257, and iv., 5, p. 287, Tauchnitz.) On his return through Gaul he settled some of the bands which had served under Sertorius in Gallia Aquitania, in a place which hence received the name of Lugdunum Convenarum (St. Bertrand). (Hieronym., *Adv. Vigilant.*, tom. iv., p. 282, ed. Monach. Benedict., Paris.)

Pompey had hitherto been constantly engaged at the head of his armies, and was totally unacquainted with the internal administration of the republic. The aristocratic party felt little gratitude for his services; for each individual among them was jealous of him, while as a body they feared him: the people, on the other hand, had long forgotten that he was the head of the party of Sulla, and saw in him only their deliverer from an enemy who had threatened to invade Italy with hosts of barbarians. On his arrival in Italy, he did not, as the laws required, dismiss his troops, for he knew that with them he might obtain anything from the senate. Crassus, a friend of the aristocratic party, had been conducting the war against the slaves; and on hearing of the return of Pompey, he had hastened to bring it to a conclusion, in order that Pompey might not snatch the laurels from him The war was indeed at an end on the return of Pompey, but he found an opportunity of cutting to pieces a body of 5000 slaves, who were on their march to seek refuge beyond the Alps, and he wrote to the senate that Crassus had indeed gained the victory, but that he had rooted out the war. Crassus felt this arrogance the more keenly, as he wished to obtain the consulship with Pompey, and was obliged to make use of the influence which Pompey had gained at his cost. Pompey, though absent from Rome, was a candidate for the consulship, and was prudent enough to recommend Crassus as his colleague. As Pompey had not yet held any of the minor civil offices, he could not legally be a candidate for the consulship. But the senate, not wishing to have the two most powerful men in the state their enemies, was obliged to suspend the laws in favour of Pompey, and he and Crassus were elected consuls for the year 70 B.C.

Pompey had now little difficulty in obtaining a second triumph, especially as he had become a great favourite with the people, and had declared that he would restore the tribunician power, which was abolished by Sulla, and would do all he could to stop the abuse which the aristocratic party made of their judicial power. The two consuls elect and Metellus stood with their armies before Rome, and on the 31st of September, 71 B.C., Crassus entered the city in an ovation, and Pompey and Metellus in triumph. Both consuls now did their utmost to gain the favour of the people, and Pompey began to fulfil his promises. The question concerning the restoration of the tribunician power had been agitated for many years, but without success; the people were now in a state of great excitement, for the abuse of their power by the senatorial party had become intolerable. When Pompey brought his rogation before the senate, the opposition was not so strong as might have been expected. Supported by his troops, which were still in the neighbourhood of Rome, by Crassus, and the exasperation of the people, Pompey carried his bill. Much may be said both for and against this restoration of the tribuneship; thus much however is certain, that the advantages were more apparent than real. Pompey had thus gradually changed his original position, and from a champion of the senatorial party, he had become a man of the people, and found himself at once by the side of Cæsar, who was already beginning to exercise an influence over him. This measure, which at the time gained him general popularity, was soon followed by another proposed by the tribune Aurelius Cotta, which deprived the senators of their exclusive possession of the judicia publica, and divided the judicial power equally among the senators, the knights, and the people, the last being represented by the tribuni Aerarii. This measure was productive of little improvement, for moral corruption was not peculiar to any one class, but pervaded the whole nation.

After the expiration of his consulship Pompey refused to go into a province, but he dismissed his army, and remained at Rome for two years without holding any office. During this time he seldom appeared in public, and never without a numerous train, which was well calculated to impress the people with his importance. He foresaw that the time was not far distant when his invincible arm would again be required to save Rome from destruction. The Mediterranean was about this time almost covered with pirates. They landed on all parts of the coast, and even in the immediate neighbourhood of Rome. The high-roads of Italy were not safe. Rome itself was suffering from scarcity of provisions, for almost all convoys bound for the city were intercepted by the pirates. The tribune A. Gabinius, a man whose fortune was completely ruined, brought forward a rogation that a consular man should be invested with unlimited powers for three years over the whole Mediterranean and its coasts to a distance of fifty miles from the sea, and that all the resources of the state should be at his disposal. No individual was mentioned, but the eyes of the people were directed to Pompey as the only man capable of saving the republic. He himself kept in the background: in the senate the rogation met with a fierce opposition, but Cæsar supported it, and thereby alienated Pompey still more from his former party. When the day came for the measure to be decided by the votes of the people, Pompey appeared in the market-place entreating the people not to draw him again into the field of action, and to appoint a more deserving general. This piece of hypocrisy had the desired effect, and the rogation was carried on the second day, notwithstanding the most violent opposition. The price of provisions immediately fell with the prospect of a speedy delivery from the pirates. However contemptible the means by which Pompey obtained the command, the manner in which he fulfilled his commission was deserving of the highest praise. The preparations for war were completed during the winter, and in the spring of the year 67 B.C. he began his operations in the Mediterranean. His legates were stationed in various quarters of the sea to draw forth the pirates and to prevent them from uniting their forces he himself with the main armament swept the sea and drove the pirates eastward. Within forty days the sea between Africa, Spain, and Italy was cleared, and Rome already felt the benefit of his exploits. He then landed at Athens, where he was received with divine honours, and after a short stay he proceeded on his expedition. The pirates who had not yet surrendered were at last surrounded and blockaded near the coast of Cilicia. Here the first and decisive battle was fought at Coracesium. The pirates were defeated, and took refuge in the town, which they surrendered after some resistance, together with all their ships and arms. Numbers of the pirates had deserted previous to the decisive battle, and the humanity with which they had been treated by Pompey contributed not a little to induce the rest to surrender. All the towns and former strongholds of the pirates opened their gates to Pompey; most of their fortresses, and everything which might enable the pirates to recover their strength, were destroyed, and they themselves were transplanted to Soloeis (henceforward called Pompeiopolis) and other deserted towns of Cilicia and Greece, where it was impossible for them again to resume their former mode of life. The whole war did not last above three months. One hundred and twenty towns and castles were occupied by the Romans, and partly destroyed; 1300 ships were burned, 72 were taken, and 306 others surrendered.

In the meantime some of his enemies at Rome began again to try their strength, but Pompey, at the head of his immense forces, and with dictatorial power over a great part of the empire, was little concerned about it, and he remained in Asia, for his object now was to be invested with the command against Mithridates. The war against this king had long been carried on with varying success, but no decisive advantage had yet been gained. The people at Rome had now the most unbounded confidence in Pompey, and when C. Manilius produced a bill (Cicero, *Pro Lege Manilia*) for giving to Pompey the conduct of the war against Mithridates, with unlimited power over the fleet and the army in the East, and with the rights of a proconsul in all parts of Asia, it was carried notwithstanding the opposition of Catulus and Hortensius. The intelligence of this decree was received by Pompey in his usual manner, with apparent dissatisfaction with those who, as he said, would allow him no peace, and would expose him to the greatest dangers in order to get rid of him. (Dion Cass., xxxvi. 28; Plut., *Pomp.*, 30.) Notwithstanding this, he immediately set out (66 B.C.) to take the place of Lucullus, whom he treated with arrogance and the neglect of all common civility.

It is a fact admitted by the antient writers themselves, that the power of Mithridates was broken before Pompey undertook the command, but it is nevertheless certain that he acted with great energy and prudence, so that the expectations of the people at Rome were fully justified. He sent his fleet round the coast from Syria to the Thracian Bosporus (Plut., *Pomp.*, 31, 32), and hastened from Crete to Galatia, where he assembled his land-troops. Proposals which he made to the king were rejected. Pompey allowed Phraates, king of Parthia, to make an attack on Armenia, and thereby made him his friend and ally. Mithridates, seeing himself thus deprived of his hope of receiving succours from Parthia (Appian, *Mithrid.*, 87; Dion Cass., xxxvi., p. 24), sued for peace; but the negotiation failed. Pompey then marched throught Lesser Armenia across the Euphrates to Acilisene, in order to separate Mithridates from Tigranes. The king took the same direction. The hostile armies met, and after some skirmishes Mithridates retreated to save his men, but he was attacked by the Romans at night in a narrow pass, where 10,000 of his army were slain and an equal number made prisoners, while Pompey only lost a small number. The king himself escaped with some horsemen to the Tauric Chersonese (Crimea). Pompey, being unable to overtake him, took up his winter-quarters in Colchis, and founded the town of Nicopolis on the field of battle in Armenia. He then advanced against Artaxata, the capital of Tigranes, who, being abandoned by his son, and discouraged at the approach of the enemy, appeared as a supplicant before Pompey, who, pleased with his submission, called him the friend of the Romans, left him in the possession of his kingdom of Armenia, and only required a contribution of 6000 talents, and his son as a hostage. A part of the Roman army remained under L. Afranius, in the country between the Euphrates and Araxes, while Pompey with the rest marched towards the north and took up his quarters on the river Cyrus (Kur), as the season was too far advanced to approach nearer the Caucasus. Here the Romans were attacked by Orœses, king of Albania (Shirvan and Daghistan), with a numerous army; but Pompey, no way daunted, defeated him; and when the king sued for peace, it was granted him on condition that he should allow the Romans a free passage through his territory.

In the year 65 B.C. the Romans had again to sustain an attack from a king of the Iberians, between Albania and Colchis; but the barbarians were routed and put to flight, and the king sent both money and his sons as hostages to the Roman general. Pompey now proceeded to the mouth of the river Phasis (Faz, or Rion), where he was joined by his legate Servilius, who had the command of the fleet in the Euxine. From him he learned that it would be useless to force his way through the Caucasian regions to the Crimea, where his army might easily be destroyed; and therefore, on receiving information of an insurrection of the Albanians, he returned to the river Cyrus. The barbarians were easily routed, and Pompey again granted peace to their king: he determined at the same time to abandon Mithridates to his own fate, and to seek richer laurels, and which were more easily to be gained, in Syria. He received ambassadors from several Eastern princes, who saw, or thought they saw, that their fate was in his hands; and even the nearest relations of Mithridates joined the Romans, and threw open to them their fortresses. Pompey, thus assured of his own good fortune, gave to Pontus the constitution of a Roman province: his fleet however was ordered to cruise in the Euxine, and to prevent provisions being conveyed to the king in the Crimea.

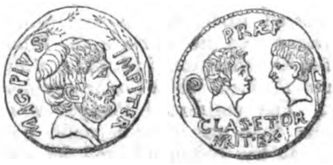
On his march southward he passed the hills of Zela, where, three years before, a legate of Lucullus had been defeated by Mithridates. Pompey ordered the bones of the slain, which still lay scattered over the field, to be solemnly buried. On his arrival in Syria he dethroned Antiochus XI., and made his country, together with Phœnicia, a Roman province. In Palestine he found a more resolute opposition. Jerusalem was distracted by a civil war between the two brothers Hyrcanus and Aristobulus: Pompey declared himself in favour of the former, and besieged Jerusalem. The town soon capitulated, but the Temple held out rather more than three months. Pompey entered the sanctuary, but did not allow his soldiers to destroy anything. Aristobulus was sent to Rome as prisoner, and Judæa recognised the supremacy of Rome by an annual tribute. In Syria, Pompey was again complimented by ambassadors from various Eastern princes: Mithridates also sent envoys, and made a last attempt at negotiation; but Pompey would hear of nothing but absolute submission, and the negotiations were broken off. Soon after, when Pompey was proceeding southward to add Arabia to his conquests, he received intelligence of the death of Mithridates; and having secured the submission of some Arabian chiefs, he hastened through Syria and Cilicia back to Pontus. Immense treasures were here surrendered to him; and Pharnaces, son of Mithridates, sent the body of his father to Pompey; but he refused to see it, and ordered it to be buried with royal honours at Sinope. Pompey now gave to Pharnaces the kingdom of Bosporus; Deiotarus, tetrarch of Galatia, was rewarded with Lesser Armenia; Bithynia, Paphlagonia, and Pontus were made a Roman province under the name of Bithynia; Cilicia and Pamphylia under the name of Cilicia and Syria. Ariobarzanes received Cappadocia, and Tigranes was allowed to remain king of Great Armenia. After he had thus settled the affairs of Asia, Pompey prepared to return to Rome, where the anticipation of his arrival called forth the activity of the several parties; some dreading his arrival with a victorious and devoted army; others, particularly the enemies of Cicero, wishing for his presence, that, as they said, he might restore the constitution, which had been violated by Cicero in his proceedings against the Catilinarian conspiracy. (Plut., *Cic.*, 23; *Cato Min.*, 26; Suet., *Cæs.*, 16.) In January of the year 61 B.C., Pompey landed at Brundusium and dismissed his armies; but he did not continue his journey towards Rome until party rage had subsided. He was everywhere received with enthusiasm, and the greater part of the population of Rome left the city to meet him before the gates, where he was solemnly received by the senate. After an interval of some months, he celebrated his triumph over the pirates and Mithridates, the most magnificent that Rome had ever beheld. Large tables were carried before him, containing an account of the countries and princes that he had subdued; and of the ships, treasures, and prisoners he had gained for the republic an immense train of waggons followed, loaded with the spoils of the East. On the second day the imperator himself entered the city, and before his chariot walked the most distinguished of his prisoners, 324 in number, and behind him followed his legates and military tribunes. His army took no part in the triumph. (Appian; Dion Cass., xxxvii. 24.) After the triumph was over, Pompey dismissed his prisoners to their native countries, with the exception of young Tigranes and Aristobulus; and with his spoils he built a temple to Minerva, with inscriptions to commemorate his victories.

After his triumph, he naturally expected that all his measures in Asia and the distribution of lands which he had promised to his soldiers would be sanctioned by the senate, especially as he thought he was secure of the support of L. Afranius, whom he had promoted to the consulship. But he found himself not only opposed by Cato and the heads of the senatorial party, but abandoned by the cowardly Afranius. This blow was too severe for a man like Pompey to bear, and he now openly joined the popular party, a step which he could not safely retract, and which involved him in those difficulties in which he at last perished. Cæsar, who was sure that he could not be outstripped in the affections of the people, supported Pompey, and thus at once weakened the power of the aristocracy, and gained over Pompey to his own interests. Crassus, the wealthiest of the Romans and the friend of the senate, was also easily gained over, and these three men now formed what is generally called the first triumvirate. During his consulship, Cæsar (59 B.C.), by his Agrarian law, enabled Pompey to fulfil the promises which he had made to his veterans: large districts of public land in Campania were assigned to them. Cæsar at length also obtained for him the sanction of the arrangements he had made in Asia before he left it. Pompey in his turn was obliged to support Cæsar, his apparent friend, in all his designs, and thus he rendered himself more and more obnoxious to the aristocratic party; while on the other hand he was neither himself sincerely devoted to the people, nor regarded by them with any other feeling than astonishment for his military success. As Pompey had divorced Mucia (Cic. *ad Att.*, i. 12) the mother of his two sons, Cæsar, to secure him still more, gave him his daughter Julia in marriage, with whom Pompey spent most of his time during this period in his villa of

Albanum near Rome, unconcerned about the sufferings of his great eulogist Cicero, who was driven into exile by the tribune Clodius; and it was not until Clodius had made an attempt to assassinate Pompey that he promoted the recall of Cicero. Gratitude induced Cicero to endeavour to re-establish Pompey in the popular favour, by procuring for him the præfectura annonæ for five years, and the proconsular power over all provinces, with fifteen legions at his command. (Cic., *Ad Att.*, iv. 1; Dion Cass., xxxix. 9.) In this capacity he went to Sicily, whence he sent provisions to Rome, and the favour of the people was easily gained, as the price of corn immediately began to fall. At the commencement of the year 56 B.C., Pompey returned to Rome, where he exerted his influence for the restoration of Ptolemæus Auletes, king of Egypt, who had been expelled from his kingdom. Clodius, who had become curule ædile, accused Milo; and when Pompey defended him, he was loaded with abuse by Clodius. This affair also involved him in a contest with the tribune Cato, who attacked him in the senate, and accused him of faithlessness to Cicero. The silence of the audience inflamed Pompey's anger, and he openly spoke of secret conspiracies against himself, pointing out his colleague Crassus as their author. He was now conscious of having lost the favour of all parties, and saw nothing left but to repair to Cæsar, who had taken up his winter-quarters at Luca, and to whom Crassus had already gone. Cæsar reconciled the two men, and, about the middle of April, 56 B.C., concluded a secret treaty with them, according to which his own governorship of Gaul was to be prolonged for five years, and Pompey and Crassus to be made consuls for the following year, with the provinces of Spain and Africa for Pompey, and Syria for Crassus. He moreover promised to exert all his influence with the people in their favour.

Pompey now returned to Rome with renewed courage and arrogance, and with Crassus was a candidate for the consulship. The opposition, headed by the inflexible Cato, who saw through the plans of the triumvirs, was fierce, though useless; but when the day of election came, it was only after the forum had been occupied by armed forces that Pompey and Crassus attained their object. The tribune Trebonius was bribed to assign to the new consuls the provinces on which they themselves had already determined. Pompey, now again at the head of the Roman world, indulged in vain dreams of a final victory over his rivals, not possessing penetration enough to see that he was preparing his own ruin, and that Cæsar was only using him as an instrument for the accomplishment of his own objects. Pompey built a magnificent theatre, and amused the multitude for several days with the most gorgeous spectacles. But the result did not entirely answer his expectations, and when he shortly after raised troops in Italy and Cisalpine Gaul, and sent them to Spain under his legates Afranius and Petreius, the people loudly expressed their discontent. At the end of the year Crassus went to Syria, but Pompey governed his province by his legates, and remained with his army in the neighbourhood of Rome, ostensibly to provide the city with provisions, but the fact was that he thus hoped to obtain dictatorial power, and to disarm Cæsar through the senate and the people without striking a blow. He interfered with the administration of justice, prevented the election of new consuls, and secretly kept up hostilities between the parties at Rome. In September of the year 54 B.C., his wife Julia died, and when proposals were made for a new alliance with the family of Cæsar, he rejected them. Crassus in the meanwhile perished in Asia, and the triumvirate was changed into a duumvirate. Pompey had long wished for the dictatorship, and when the tribunes Lucceius Hirrus and Cœlius Vinicianus prevented the elections, and at last proposed to make Pompey dictator, he was obliged openly to come forward, but perceiving the vehement opposition of the senate and Cato, he withdrew, and Domitius Calvinus and Valerius Messala were elected consuls for the remainder of the year. At the end of their consulship, the elections were again disturbed, and Pompey conceived fresh hopes. In the ensuing quarrels between Milo and Clodius [CICERO], the senate, unable to maintain peace and order in the city, empowered Pompey to collect troops, and to put an end to the disturbances. Pompey was now again in his proper sphere: his first object was, with the assistance of his soldiers, to thwart the plans of Milo, and to get rid of him he not only introduced new forms of procedure, but also surrounded the court with soldiers during the trial of Milo. Milo was exiled, while others who were equally guilty were acquitted, as Pompey had no ground for fearing them. On the 25th of February, Pompey was made sole consul, but on the 1st of August he made Metellus Scipio, whose daughter Cornelia he had married, his colleague, and with him held the comitia to elect the consuls for the year following. At the same time an old law, that in many instances had been neglected, was renewed, which required that every candidate for a public office should be a candidate in person at Rome. This was manifestly aimed at Cæsar, who thereby would be compelled to give up the command of his armies and to appear in Rome, if he wished to be a candidate for the consulship. For himself Pompey obtained a prolongation of his proconsulship over Spain for five years. While Pompey, during whose illness at Naples all Italy prayed for his recovery, was more and more confirmed in his conviction that he was the first man of the republic, Cæsar had by the distribution of large sums of money increased his party at Rome, and gained over to his interest several tribunes, among whom was the bold and eloquent Curio. Cæsar, though absent from Rome, claimed to be elected consul for the following year; and when Pompey and the senate required him to dismiss his army and present himself at Rome as a candidate, Curio insisted that Pompey should likewise dismiss his army. [CÆSAR.] After long discussions, the party of Pompey gained the day, and a decree was made declaring Cæsar a public enemy unless he resigned his command and came to Rome as a private man. The public authorities at the same time received orders to guard the republic against any danger, and Pompey was allowed to make use of the public treasury for the purpose of raising an army in Italy. Pompey had declared that he only needed to stamp with his foot upon the earth to call forth new legions; but when he found that he had miscalculated, he and the whole senatorial party were thrown into the greatest confusion by the intelligence that Cæsar was advancing towards Rome. On this occasion Cicero exclaimed, 'Pompey, thou hast betrayed us!' Cato however thought it advisable to declare Pompey general of the republic. Pompey with his few troops could do nothing; he left the city accompanied by the consuls, most of the senators, Cato, Cicero, and others of the aristocratic party; they hastened to Capua, and thence to Brundusium. The consternation among those who were obliged to remain in the city was indescribable; they dreaded a renewal of the scenes that they had witnessed under Marius and Sulla. But Cæsar by his moderation won the hearts of all. From Brundusium Pompey fled to Dyrrhachium in Epirus, which he strongly garrisoned and fortified, while Cæsar established his power in the West. The position of Pompey was more advantageous to him than any other he could have chosen, for the fleet was at his command, and he could raise new troops without great difficulties; but he had to struggle with his own party, some blaming him for not offering battle to Cæsar, and others for not accepting the proposals of peace which Cæsar repeatedly made to him. His own plan was to weaken his enemy without fighting a battle. But Cæsar received reinforcements from Italy, and Pompey was cut off from Dyrrhachium; in a battle which ensued, Cæsar was defeated, and directed his march into Thessaly. After this success, the senatorial party imagined that all the work was done, and that they might without any danger return to Italy; and when Pompey declared that Greece must first be cleared of the enemy, they urged the immediate necessity of battle. Cæsar knowing this disposition of his adversaries, compelled them, on the 9th of August, 48 B.C., to give battle in the plains of Pharsalus. Pompey was defeated, and though he had still considerable forces at his command, he was disheartened. He fled to the mouth of the river Peneus, and thence sailed to Lesbos, whither he had sent his wife Cornelia and his younger son. By the advice of one of his friends he determined to seek refuge in Egypt, whose king was indebted to him for the restoration of his father. He landed there on the 28th of September, but was treacherously murdered in the presence of the king and his army by the tribune Septimius, at the instigation of Achillas and Theodotus, who feared the anger of Cæsar. The wife and child of Pompey, who were still on board the ship, and saw the murder, hastened away. The murderers cut off the head of Pompey and left the body on the beach, where it was buried by a freedman and a veteran. Cæsar, who arrived in Egypt three days later, shed tears at the sight of the head of Pompey, and put his murderers to death.

Pompey was 58 years old at the time of his death. It is difficult to form a correct judgment of his character, for he was not, like Marius, Sulla, and Cæsar, a man of singleness of principle and purpose, but he changed his position according to the circumstances in which he was placed, and which he was unable to control. Though by birth not belonging to the senatorial party, he was by his immense fortune placed on a level with them, and made himself their champion, though they could never sympathise with him; for the people he had no heart, and when he joined the popular party, it was solely to satisfy his own ambitious views. He was thus in reality throughout his life floating between two parties, and was neither in his private nor public life a faithful friend. His only object was to be looked upon as the first man of the state, and he objected to no means of accomplishing this end, even though they tended to subvert the constitution. In his civil administration of the state, and during the whole period from his great triumph to the war with Cæsar, the little that he did was not calculated materially to improve the condition of his country. Ambition and vanity were the leading features of his character, and a calculating selfishness pervaded everything that he did. His real fame must rest on his conduct as a general, though he was inferior in this respect to most of the great generals of his age. In his private life he formed indeed a contrast with most of his contemporaries, for though immensely rich, he lived simply, abstained from all debauchery and excesses, and was faithful in his matrimonial relations. It is also generally acknowledged that he did not enrich himself by extortion in his provinces, though no man had ever had more opportunities, and that he was conscientious in the application of the public money. As regards his intellectual powers, he was not above mediocrity, although he sometimes affected to be the patron of science and literature. Cicero judged of him differently at different times, according as he was governed by momentary impulse or by what he considered the good of the state. His features in his statues and busts are, according to Niebuhr, expressive of a high degree of vulgarity and rudeness: others think them majestic and imposing. (See the articles CICERO, CÆSAR, SERTORIUS, MITHRIDATES, and especially Pompey's Life in Drumann's *Geschichte Roms, &c.*, vol. iv., p. 324-556.)



British Museum. Actual Size.

This coin was not struck by Pompey himself, but by his son Sextus, as appears from the surname *Pius* in *Magnus Pius, Imperator iterum, Præfectus classi et oræ maritimæ ex Senatus consult.* It must have been struck at the time when Sextus had taken possession of Sicily and assumed the title of Imperator for the second time. The single head on one side is that of Pompey the Triumvir; the two smaller heads are those of his two sons. But there are still some difficulties:—1. The hair in this portrait of the father seems to fall smoothly down the forehead, though Plutarch says that, on the contrary it was bristly and rose upwards, as is seen on one of the smaller heads. 2 The *lituus* is not easily accounted for, as neither of the sons ever held the office of augur. The portrait of Pompey is also found on the coins of Pompeiopolis, which town honoured him as its founder. Comp. Eckhel, 'Doctr. Num. Vet.,' iii., 69, and Vaillant, *v.* 'Pomp.'

POMPEIUS, CNEIUS MAGNUS, the elder of the two sons of the triumvir Pompey and of Mucia. He was born about 77 B.C. According to Appian, he and his brother Sextus accompanied their father on his expedition against the pirates. When the war with Cæsar broke out, he was sent to Egypt to collect troops, and when he returned to his father's fleet in the Adriatic with 500 horsemen and 50 ships, and found that Cæsar had been allowed to cross the Adriatic, he felt very indignant and burnt several of the hostile ships. After the defeat of his father, he sent his squadron back to Alexandria and remained with the main armament near Corcyra, justly observing that with such a fleet there could be no reason for despair. In the spring 47 B.C., when sailing with the fleet to Africa, he was informed by his brother of the murder of his father. The aristocratic party, whose interests were now distinct from those of the family of Pompey, did not wish young Cneius Pompey to be among them in Africa, and sent him to Spain, where he might prepare for them a refuge if they should be unsuccessful in their contest. Cneius, after having taken possession of several small islands, landed in Spain (46 B.C.), where he was shortly after joined by his brother Sextus, who had left Africa after the defeat of the senatorial party at Thapsus. Cneius soon collected an army of 13 legions, but Cæsar did not at first think him an adversary of any consequence, and sent only his legate C. Didius against him. At the end of the year however he found it necessary to follow himself. On the 17th of March, 45 B.C., Cneius was defeated in the bloody battle of Munda (Monda in Granada), and flying to Carteia, attempted to escape across the sea. Being thwarted in this attempt, he directed his steps towards the interior of Spain. His enemies followed, and overtook him in the neighbourhood of Lauron, where he was killed. Being naturally of a passionate disposition, the fate of his father had filled him with an insatiable desire of revenge, and changed his natural boldness into a kind of savage audacity. See the article CÆSAR, and the detailed account of the war in Spain in the book *De Bello Hispaniensi.*

POMPEIUS, SEXTUS MAGNUS, the younger son of the triumvir and of Mucia, was born in 75 B.C. At the time of the war with the pirates he was a boy of eight years of age, and when his father fought the battle of Pharsalus he was with his stepmother Cornelia in Lesbos. After witnessing the murder of his father in Egypt, he fled with Cornelia to Cyprus, and soon after joined his brother Cneius, who was sailing with the fleet to Africa. When the senatorial party was defeated at Thapsus, he went with Labienus and others to Spain to rejoin his brother, but stopped at Corduba. After learning the unhappy issue of the battle of Munda, he left Corduba, and for a time wandered about as a robber in the country of the Lacetani. A number of malcontents and fragments of the army of his brother soon assembled around him, and with them he began to carry on a kind of guerilla warfare. Supported by the natives (Dion Cassius, xlv. 10), he took several towns, and neither C. Carrinas nor Asinius Pollio was able to cope with him. He soon made himself master of all Bætica and a part of Hispania Tarraconensis, and assumed the title of imperator. The only object of Sextus, as he himself afterwards declared, was to be restored to his country and to recover the confiscated estates of his father. (Cic., *Ad Att.*, xvi. 4.) It was proposed in the senate to recall him and to give him from the public treasury a sum of money equivalent to the property of his father. The proposal was supported by Antony; but Sextus, mistrusting the optimates as well as the veterans of Cæsar, advanced with his forces as far as Massilia to watch the course of events in Italy. The senate made him chief admiral of the fleet, but when Octavian, Antony, and Lepidus formed a new triumvirate, Sextus was declared an outlaw. Being however supported by his fleet, he cruised as a pirate in the Mediterranean, and at last succeeded in taking possession of Sicily. The number of proscribed or ruined individuals and of slaves who flocked to his standard increased daily, as he promised them higher rewards than his enemies offered for his head. He also received reinforcements from A. Cornificius, governor of the province of Africa. (Dion Cass., xlviii. 17.) Rome at this time suffered from scarcity, and Octavian sent out Q. Salvidienus Rufus (42 B.C.) with a squadron, who however only succeeded in protecting the coasts of Italy. During the campaign of Philippi, Sextus remained inactive, confining himself to the defence of Sicily, and only harassing the coasts of Italy, whereby he increased the scarcity of provisions at Rome. When, in the spring of the year 40 B.C., Antony on his return from Egypt found the gates of Brundusium closed upon him by Octavian, he requested Sextus Pompey to assist him against Octavian. Pompey without hesitation sent a division of cavalry and a squadron to southern Italy. But the triumvirs soon became reconciled, and after concluding a fresh treaty among themselves (fœdus Brundusinum), they determined to make war upon Pompey, who now recommenced cutting off all supplies from Rome. The city was thus thrown into such a state of suffering and discontent, that at last the people in open rebellion compelled the triumvirs to a reconciliation with Pompey. In 39 B.C. a treaty was concluded with him, in which he obtained the proconsulship of Sicily, Sardinia, Corsica, and Achaia, and promised to supply Italy with provisions. But this reconciliation proved to be little more than a farce, for when Sextus returned to Sicily, Antony refused to give up Achaia, and Octavian complained that Pompey allowed piracy to be carried on in the Mediter ranean. A rupture between Pompey and Octavian ensued, and Menodorus, the admiral of the former, went over to Octavian, and treacherously surrendered to him Sardinia and Corsica. Octavian was now bent upon destroying the Pompeian party, but his fleet was twice defeated by the admirals of Pompey, first near Cuma and then near Messina. Pompey however, as usual, did not avail himself of his victories, and allowed Octavian to repair his losses. The faithless Menodorus now returned with seven ships to his former master. M. Vipsanius Agrippa was appointed by Octavian as chief admiral of his fleet, and a landing was to be made on three parts of the island of Sicily at once; but the fleet was dispersed by a storm, and Lepidus alone reached Lilybæum. Pompey even now remained inactive, and offered sacrifices to Neptune, whose son he called himself. (Dion Cass., xlviii. 19; Horat., *Epod.*, 9.) Menodorus again deserted Pompey, and in a sea-fight off Mylæ against Agrippa, Pompey lost 30 ships and was unable to prevent Octavian from landing at Tauromenium. After several skirmishes, Agrippa at length (36 B.C.) in a great sea-fight near Naulochus decided the fate of Pompey, who, when he heard of the desertion of his land-troops, fled with his daughter and 17 ships from Messina to Asia. He was not followed by Octavian, and found an hospitable reception with C. Furnius, the legate of Antony. But he soon lost the confidence of his host by sending secret envoys to the Parthians and taking possession of Lampsacus. An open war broke out between him and Furnius, and when Antony, who was at the time in Alexandria, heard of it, he sent Titius with a fleet of 120 ships against the dangerous guest. Pompey fled to Armenia, but being overtaken by his enemies and deserted by his troops, he surrendered, and was put to death at Miletus (35 B.C.), either at the command of Antony himself or of Titius, who wished to remove a man who might easily be the cause of a rupture between the triumvirs.

Sextus Pompey was 40 years old at the time of his death. He had been deprived of all that was dear to him, and was drawn into a war which he would willingly have avoided, if he could have been restored to his country and could have recovered his property without it. In his undertakings he owed almost all his success to favourable circumstances and to the great reputation of his name, for he himself was neither active nor prudent. (Vel. Pat., ii., 73, 79; Cic., *Ad Att.*, vi. 4.) He assumed the name of Pius, because he endeavoured to avenge the death of his father and his brother: this surname appears on many of his coins. [Pompeius, Cneius.]

POMPEIUS, TROGUS. [Trogus.]

POMPEY'S PILLAR. [Alexandria.]

POMPILUS, according to Latreille, a genus of Hymenopterous insects of the section Fossores and family Sphegidæ. In the systems of Dr. Leach, Mr. Shuckard, and some others, this group of insects is regarded as a family, Pompilidæ, the principal characters of which are as follows:—posterior legs at least as long as the head and thorax taken together; antennæ of the female formed of long joints, generally distinct and often curved; prothorax at least as broad again as long; its posterior margin arched; abdomen obovoid, without any long petiole at the base.

The Pompilidæ are extremely active: they run and fly with great rapidity, are for the most part of moderate size, and often adorned with red and black colours;—at least those species which belong to the genus *Pompilus*. These insects burrow in the ground, preferring sandy situations, and store their cells with spiders, which constitute the food of their larvæ.

In the genus *Pompilus*, the superior wings have one marginal cell, which is semicircular, and sometimes nearly triangular; and three submarginal cells; the first of these is as long or longer than the two following cells; the second receives the first recurrent nervure about its centre; and the third, which is either triangular or subquadrate, receives the second recurrent nervure. A fourth submarginal cell is sometimes traceable.

This genus contains numerous species. Mr. Shuckard, in his work on the indigenous Fossorial Hymenoptera, describes eighteen species.

Besides Pompilus proper, the genera *Ceropales* and *Aporus* are included in the present family. An account of these genera and of the English species they contain will be found in Mr. Shuckard's work.

POMPION. [Pumpkin.]

POMPONIUS SEXTUS, a distinguished Roman jurist. His age may be approximated to from several circumstances. He is supposed to be the Sextus mentioned by Gaius in connection with Julianus (ii. 218). In the extract from the 'Liber Singularis' of the 'Encheiridion' of Pomponius (*Dig.*, i., tit. 2, s. 2), we have a list of the various Roman jurists, ending with Salvianus Julianus, from which circumstance it may be concluded that he was at least younger than Julianus. A difficulty however arises from the fact of a Pomponius being often cited by Julianus (*Dig.*, iii., tit. 5, s. 6), and from there being cited in the 'Digest' both a Sextus Pomponius and a Sextus and a Pomponius. (*Dig.*, xxx., tit. 1, s. 32.) Sextus Pomponius is cited by Pomponius. (*Dig.*, xxviii., tit. 5, s. 41.) On the whole it seems likely that there was a Pomponius and a Sextus Pomponius who was sometimes simply called Sextus. But if there were two, it is difficult to say when they respectively lived or what they respectively wrote. Pomponius survived the emperor Antoninus Pius. (*Dig.*, l., tit. 12, s. 14.) In one passage he calls Gaius (*Dig.*, xlv., tit. 3, s. 39) 'Gaius noster.' From all these circumstances it may be concluded that a Pomponius lived under Antoninus Pius and survived him. If there was a Sextus Pomponius, he was older than Pomponius. The works of Pomponius, as cited in the Florentine Index, are thirty books 'Ad Q. Mucium Lectionum,' thirty-five to Sabinus, twenty books of Epistolæ, fifteen books of Variæ Lectiones, seven books to Plautius, five books of Fidei-commissa, five books of Senatus consulta, five books of Regulæ, and two books of the Encheiridion.

The 'Encheiridion,' as extracted in the 'Digest,' is called 'Liber Singularis.' It contains an historical sketch of the origin and progress of the Roman law, and a list of the law writers to the time of Pomponius, in which it is also mentioned what writers respectively belonged to the schools of Ateius Capito and Labeo, who lived in the time of Augustus, and were the founders or heads of two separate schools (scholæ).

POMPONIUS MELA. [Mela.]

POMPTINE or PONTINE MARSHES (*Paludi Pontine*, in Italian) is the name of a low marshy plain in the Papal State, about 24 miles long from north-west to south-east, from For. Appio to Terracina, and varying from eight to ten miles in breadth. It is bounded on the east by the Monti Lepini. On the west it is bounded by a range of downs from 30 to 60 feet high, which begin on the south at Mount Circeo, an insulated calcareous mountain 1600 feet high, which juts out into the sea, and thence run to the northwards parallel to and at the distance of from two to three miles from the coast, leaving a belt of land between them and the sea, which is partly covered by forests and partly occupied by lagoons. This belt has no water communication with the basin of the Pomptine marshes. From Mount Circeo eastward to Terracina, another ridge of downs of much smaller dimensions runs close to the sea-coast, and is cut through by the canal called Portatore di Badino, which is the great outlet of the waters of the Pomptine marshes. On the north and north-west the Pomptine marshes border on the dry plains of Cisterna and Sermoneta, from whence the general slope of the surface is to the south-east, in the direction of the length of the marshy plain, on one side of which the ground rises gently towards the Lepini ridge, and on the other towards the terrace or downs above mentioned. The greatest depression is towards the south-east extremity, where an extent of about three or four square miles is below the level of the sea. All the rest of the surface of the plain is above the sea-level, being about 18 feet at For. Appio at the north-west or upper end of the marshes, and declining gradually along the centre of the plain, until it is only five feet at the point where the waters flow into the canal or æstuary of Badino.

The rivers which flow into this basin are, beginning from the north,—1, La Tepia, a muddy stream which rises in the heights of Giuliano and Cori, east of Velletri; 2, the Ninfa, which has its source at the foot of the mountain on which Norma is built; 3, the Cavata, which issues out of a small lake near Sermoneta; 4, the Ufente, a clear perennial stream which rises at the foot of the Monti Lepini, near Casenuove, not far from Sezze; 5, the Amazeno, which rises in a deep valley of the Monti Lepini, called Vallecorsa, and drains a considerable tract of country before it enters the Pomptine plain by a narrow defile below Piperno; 6, the Pedicata, a smaller stream which rises in the mountains of Sonnino. The French engineer Prony demonstrates in his able work (*Description Hydrographique et Historique* *des Marais Pontins*, 4to., with an Atlas, Paris, 1822), that one-half at least of the water which flows into the plain of the Pomptine marshes is derived from subterraneous drainings of the more elevated neighbouring basins of the Sacco, the Liris, and the Anio, as the average quantity of rain which falls upon the whole extent of the Pomptine basin is not equal to one-half of the quantity of water which finds its way into the sea through the æstuary of Badino. The river Ufente alone, which issues out of a rock, having no apparent upper basin or drainage to feed it, is sufficiently large to turn mills and bear loaded boats near its source.

There is every appearance that the basin of the Pomptine marshes was once a gulf of the sea, which has been gradually filled up by alluvium from the mountains. The oldest historical records exhibit this tract as occupied by the Volsci, who had numerous towns, some of which were situated in the most marshy part of the country. One of these towns, called Suessa Pometia, which was destroyed by Tarquin the Proud, is supposed to have given its name to the whole region. The country was evidently very fertile, for we read in Livy (iv. 25) that in the year 322 of Rome the Romans in a season of scarcity sent to the Pomptine ager for a supply of corn. In the years 367-8 the tribune L. Sicinus proposed a distribution of the lands of that district among the poorer citizens. About 442 of Rome, the censor Appius Claudius Cæcus constructed the fine road which still bears his name across the length of the Pomptine region, the soil of which must have then been sufficiently compact to bear the great weight of the causeway. The level of the original ground on which it was constructed has been found to be about four feet above the sea-level, at a distance of 12 miles from the coast. But on arriving at the foot of the rock of Feronia, Appius found that if he continued the road in a straight line, he must pass through a soft marshy tract, and he was induced to deviate from the direct line in order to avail himself of the more solid ground which lay near the foot of the Monti Lepini. At some period of the century and a half that followed the building of the Appian way, the country seems to have undergone great deterioration, either from natural or civil causes, and to have become partly inundated, for we find the consul Cornelius Cethegus, in the year of Rome 592, applying himself to the draining of the marshes and restoring the land to cultivation, and it was then that new towns arose on the ruins of the antient towns of the Volsci, under the names of Tres Pontes, Tres Tabernæ, ad Medias, &c.

The civil wars and the devastation which accompanied them again caused the hydraulic works of the Pomptine marshes to be neglected, until Augustus made or restored several canals, especially a navigable canal which followed the line of the Via Appia, and upon which Horace performed part of his journey to Brundusium (*Sat.* i. 5). Nerva and Trajan restored parts of the Via Appia which had sunk, and Antoninus Pius constructed a port at Terracina. After this we find no more records of the Pomptine marshes till the reign of Theodoric, who turned his attention to the draining of this tract, and charged a patrician named Cæcilius Decius with the execution of his orders. After that epoch we know no more of the state of the country until the end of the thirteenth century, when Pope Boniface VIII., whose family, the Caetani, were feudal lords of Sermoneta and of the greater part of the Monti Lepini, constructed some works for the drainage of part of the marsh. Leo X. employed the engineer Giovanni Scotti to repair and enlarge the canal of Badino, which is the great outlet of the marshes. Sixtus V. constructed a lateral canal, which, running nearly parallel to the Via Appia, receives the waters of the western part of the marshes and carries them to the common æstuary of Badino. This canal is still called Fiume Sisto. Notwithstanding this, the Pomptine marshes were in a deplorable state when Pius VI. ascended the pontifical throne in 1774. All the canals were encumbered with mud, about 60,000 acres were under water, the Via Appia was covered with alluvium and aquatic plants, and a few sickly fishermen were the only inhabitants of the region. Lalande, in his 'Voyage en Italie,' gives a lamentable description of the appearance of the country in 1766. In 1777 Pius VI., after having consulted Boscovich, Ximenes, Manfredi, and other mathematicians, entrusted the draining of the Pomptine marshes to Rapini, an engineer of Bologna, who had acquired a reputation by his hydraulic labours in the territory of his native town. The pope began by purchasing that part of the ground which was entirely covered with water from those who had prescriptive rights to it. He then suggested to Rapini, in a letter dated 17th of January, 1777, that the best plan of drainage would be by digging a capacious canal along the whole length of the marshes parallel to the line of the antient Appian road, which should be restored at the same time. In 1778 the works began. Rapini began by clearing the canal of Badino as far as where it meets the Via Appia, and he then began to excavate a canal parallel to that road. As he proceeded on his work, which could only be carried on during the winter and spring months on account of the pestilential air of the summer months, he had the satisfaction of seeing the waters lower, and the old causeway of the Via Appia, with its arches and bridges, emerge from the stagnant lagoon in which it had been buried for ages. From seven to eight thousand workmen were employed for more than three years, and at last, in 1781, the excavation of the canal was carried as far as Forum Appii, at the upper extremity of the marshy regions. The canal, thus opened in a straight line of about 14 miles long, was appropriately named 'Linea Pia.' It is from 40 to 50 feet wide and 9 feet deep, and is embanked the whole length.

Rapini afterwards cleared the lateral or western canal, called Fiume Sisto, and introduced into it the waters of the Ninfa and of the Tepia from the upper part of the marshes. This important canal, which describes a curve of nearly 30 miles in length, is from 20 to 30 feet wide.

In the eastern part of the marshes a new bed was dug and embanked for the river Ufente, and was made to join the Amazeno at Ponte Maggiore, after which the united stream joins the Linea Pia. Two other canals, called Schiazza and Botte, were excavated parallel to the main canal, with cross cuts at the distance of one mile each, which open into the Linea Pia so as to drain the intermediate space.

Lastly, a branch of the Portatore, or great emissary, was made to run into the port of Terracina in the shape of an embanked and navigable canal. All these works, which lasted about fifteen or sixteen years, cost Pius VI. only nine millions of francs, or 360,000*l.* sterling. Rapini having died, his son-in-law Astolfi continued the works; but unfortunately the state of the papal treasury and the confusion resulting from the French revolutionary invasion prevented their completion. Some years after, when Napoleon took possession of the Papal State, a commission was appointed to superintend the hydraulic works of the Pomptine marshes, and 200,000 francs were granted annually for the purpose of draining them. A fresh embankment of the Amazeno, a rapid current, was effected, and the intermediate canal of Schiazza was lengthened, in order to drain more effectually the space between the central line and the Monti Lepini. With regard to the western portion of the marshes, several engineers advised that advantage should be taken of a colossal excavation called traditionally Rio Martino, but which probably dates from the Roman times. This canal is cut across the western downs, and affords a direct communication between the middle part of the marshes and the sea; it is about 5000 feet long, from 60 to 100 feet wide, and about 40 feet deep. By clearing and continuing this excavation to the sea, it was proposed to make it the common emissary of the Tepia and other streams which flow through the upper or north-west part of the marshes, and which are now apt to encumber the canal called Fiume Sisto with their deposits. But Prony objected to this plan, because he thought it necessary not to diminish the current of water which runs out through the æstuary of Badino. Consequently the Rio Martino has remained useless. Since the Restoration, all that has been done for the Pomptine marshes has been to maintain the drainage in the state in which Pius VI. left it, by keeping the canals clear and the dykes in repair. The greater part of the plain is covered with rich pastures, in which are fed numerous herds of horned cattle, and other parts of it are sown with rice, wheat, and Indian corn, and afford rich crops. In the spring, before the great heat renders the atmosphere unwholesome, it has the appearance of a most delightful region. But, except the post stations along the high road, and some scattered huts here and there, there is no permanent population throughout the whole of the plain. The great æstuary of Badino is between 70 and 80 feet wide; there is about 4 feet water over the bar, and nearly 10 feet water inside of it, where boats find a safe anchorage.

Further details concerning this interesting country are found in the works of Prony; Nicolai, *Dei Bonificamenti delle Terre Pontine;* Bolognini, *Memorie dell' antico e presente Stato delle Paludi Pontine;* and Tournon, *Etudes Statistiques sur Rome.*

PONANG. [Hindustan, vol. xii., p. 204.]

PONCE DE LEON, RODRIGO, born in 1443, was an illegitimate and younger son of John Ponce de Leon, Count of Arcos, a Castilian nobleman, and Doña Leonora Nuñez de Prado, a lady of rank. The brilliant qualities of the youth so far gained him the affection of his father, that he asked and obtained the royal sanction to bequeath him his title and estates, to the prejudice of legitimate heirs. He served his apprenticeship to the art of war in the various campaigns against the Moors, displaying on every occasion the greatest ability and personal courage. When scarcely seventeen years old, he obtained at Madroño a victory over the Moors, accompanied with a signal display of personal prowess. Having stopped to adjust his buckler, which was unlaced, he was suddenly surrounded by a party of the enemy; he however snatched a sling from one of them, and made so good a use of it, that after disabling several, he compelled the rest to take to flight; for which feat of arms the king complimented him with the title of the youthful David. At the death of his father, in 1469, Rodrigo succeeded him in his title, and soon after married the daughter of the Marquis of Villena, the minister of Henry IV., through whose influence he was raised to the dignity of Marquis of Cadiz. This alliance attached him to the fortunes of Henry, in his disputes with his brother Alfonso, and subsequently with Isabella, on the accession of the latter to the throne of Castile. Rodrigo did not engage in any open act of resistance; but retired to his estates, and occupied himself entirely in prosecuting an hereditary feud with the house of Guzman, a family which from antient times divided with his own the interests of Andalucia. In the glorious wars which put an end to the Mohammedan power in the Peninsula, the marquis took a very active part. Having early in 1482 received intelligence that the important fortress of Alhama was but slightly garrisoned, he marched up to it, and succeeded in scaling the walls and surprising the garrison. In 1483, he accompanied a marauding expedition against Malaga, headed by the grand-master of Santiago, Don Alonso de Cardenas, who entrusted to him the command of the centre; but being suddenly attacked and surrounded by considerable forces of the enemy, whilst in the intricate passes of the Axarquia, the Christian army was completely routed, and very few knights escaped alive. The marquis, after performing prodigies of valour, succeeded in extricating himself from the peril, and escaping with a few followers. During the siege of Velez (April, 1487) he saved the life of Ferdinand, who, having been surrounded by a party of the enemy, must inevitably have perished without his timely aid. He also greatly distinguished himself during the siege of Malaga (May, August, 1487) by repulsing a sally made by the garrison, and he was present at the surrrender of Baza (1488) and Granada (January, 1492). This gallant soldier survived only a few months the close of the Moorish war, to which he had so efficiently co-operated. He died in his palace at Seville, on the 28th of August, 1492, from the effects of a disorder brought on by the fatigues of his military life. At his death, Ferdinand and Isabella, with all their court, went for several days into deep mourning.

(Bernaldez, *Cronica de los Reyes Católicos, Genealogia de los Ponces de Leon;* Prescott, *Ferdinand and Isabella.*)

PONCE DE LEON, JUAN, one of the early Spanish discoverers in America, was a native of Leon in Spain, and when a boy was page to Pedro Nuñez de Guzman, Señor of Toral. From an early age he had been schooled to war, and served in the various campaigns against the Moors of Granada. He accompanied Columbus in his second voyage in 1493; and having subsequently distinguished himself in the campaign against the Indians of Higuey, he was appointed to the command of the conquered territory, as lieutenant of the governor of Hispaniola. In 1508, having received intelligence from the natives that the mountains of the neighbouring island of Boriquen, or Puerto Rico, abounded with gold, he applied to the governor Ovando for permission to make an expedition to the island, and having obtained it, sailed thither, in a caravel, with a few Spaniards, and several Indians to act as interpreters or guides. Ponce landed near the residence of the principal cacique, Agueybaná, who treated him and his suite with great kindness, and gave them a large quantity of gold. With these good tidings Ponce returned to Hispaniola, and obtained from the governor permission, as well as the necessary supplies, to undertake the subjugation of the island. Before the supplies were completed however, his patron Ovando was recalled, and succeeded by Don Diego Columbus, who deprived Ponce of his command, and appointed another governor over the island. In the meanwhile Ovando, who had now returned to Spain, having made a favourable representation of his merits, Ponce was re-appointed in 1509, and entrusted with the conquest of the island. After many hard-fought battles with the natives, who proved to be far more warlike than those of Hispaniola, and the death of their cacique Agueybaná, who fell in a skirmish, Ponce completed the subjugation of the island; notwithstanding which he was again deprived of the command, and replaced by Juan Ceron. Incapable of quiet life, Ponce soon turned his eyes to some other scene of conquest. He appears to have conceived the singular idea that there was yet a third world to be discovered, and he hoped to be the first to reach it; but as he was then fast advancing in life, and his constitution had been very much impaired by the fatigues and privations of former voyages, he decided to sail first to a certain island of the Bahama group, called Bimini, where, according to a tradition current among the natives of Puerto Rico, was a fountain possessing the power of restoring youth. In search of this marvellous fountain Ponce sailed, on the third of March, 1512, from the port of St. Germain in the island of Puerto Rico. Having arrived at the Bahamas, he visited all the islands, one after another, and drank of every fountain, river, or lake that he found; but his inquiries for the island of Bimini were all in vain. Ponce however was not discouraged; and after repairing his ships, he again put to sea, and shaped his course to the north-west. In this way, on Sunday, the 27th of March, he came in sight of what he supposed to be an island, which, from the circumstance of its being discovered on a Palm Sunday, and the ground being covered with flowers, was called 'Pascua Florida.' Ponce took possession of the country in the name of Ferdinand and Isabella, and again started in search of the desired island; but after some months of unsuccessful cruise, he returned to Puerto Rico, and thence to Spain, where he arrived in 1513. Having made a report of his voyage to the king, he was appointed Adelantado de la Florida, and in 1514 entrusted with the command of an expedition fitting out at Seville against the Carribees. This however proving unsuccessful, Ponce retired to Puerto Rico, where he resided until 1521, when, being roused by the fame of the recent exploits of Cortés [Cortes], he again fitted out two ships, and, having embarked almost the whole of his property, put to sea. In this manner he came upon the western coast of Florida, where he made a descent; but the Indians sallying forth to defend their shores, several of his men were slain, and himself wounded by an arrow in the thigh, of which he died soon after, at Cuba, in 1521.

(Herrera, *Historia de las Indias*, dec. 4, lib. ix., cap. viii., ix.; Navarrete, *Coleccion de Viages y Descubrimientos*, &c., vol. iii.)

PONCE, PEDRO, a Spanish Benedictine monk, in the convent of Oña in Old Castile, was born about the year 1530. He is considered the inventor of the art of teaching the dumb to speak, which he carried to such perfection as to make us doubt whether Braidwood, L'Epée, Sicard, and others accomplished more than he did. [Deaf and Dumb, p. 326.] According to Ambrosio Morales (*Antiguedades de España*, Alcalá, 1575, fol. 38), Ponce had to instruct two brothers and one sister of the Constable of Castile, and a son of the Gran Justicia of Aragon, all of whom were born deaf and dumb. These pupils made such progress, that after some time they not only were able to write correctly, but also to answer any questions put to them. One of them, Don Pedro de Velasco, who lived to be only twenty years of age, spoke and wrote Latin as well as his mother tongue, and was at the time of his death making considerable progress in the Greek language. His own account of himself is thus recorded: 'When I was a child, I knew nothing; I began first to write down the things which my master showed me, and afterwards I wrote down all the Spanish words in a book which was made for that purpose. Afterwards, with God's assistance, I began to spell, and then to pronounce, with all the force I could, though much saliva came from me,' &c.

Mr. Southey says that 'another of Ponce's pupils became a Benedictine monk, and was able to make confession, and explain his creed by word of mouth.' These facts would appear almost incredible, were they not universally attested by the best Spanish writers of the time, as well as by our countryman Sir Kenelm Digby, who, in his 'Two Treatises concerning the Body and Soul of Man' (Paris, 1644, cap. 28, n. 8), says, 'This priest brought the young lord to speak as distinctly as any man whosoever; and I have often discoursed with him whiles I wayted upon the Prince of Wales in Spaine.' According to the same author (p. 254) and to Juan de Castañiza (*Vida de San Benito*), Ponce wrote a treatise in Spanish, in which he explained his method, and laid down certain rules as the result of his observations; but this interesting work has been lost, though it is generally believed that Juan Pablo Bonet, who in 1620 published his *Reduccion de las Letras, y Arte para enseñar á hablar los Mudos*, 1620, 4to., saw and consulted it. Ponce died in 1584, and was buried in the convent of his order.

POND, JOHN, was born about 1767, and was successively at Maidstone grammar-school, under the tuition of Wales, known as astronomer to Captain Cook's expedition, and at Trinity College, Cambridge. Having been obliged, from the ill health which attended him almost through life, to spend several years abroad, he settled himself, on his return, at Westbury near Bristol, where he resided till his marriage in 1807. He then settled in London; and in 1811 was appointed to succeed Dr. Maskelyne as astronomer royal. He retired from this office upon a pension in 1835, and died September 7, 1836, at Blackheath. He was buried at Lee near Blackheath, in the same tomb with his predecessor Halley. (*Monthly Notice of the Royal Astronomical Society*, for February, 1837.)

Mr. Pond's attention was directed to astronomy by Wales, to whom it is stated that, when a boy, he pointed out some apparent imperfection of the Greenwich instruments, as shown in their published results. He did not continue this study at Cambridge, and missed the opportunity of acquiring that depth of mathematical knowledge which is necessary for the comprehension of the highest branches of the theory of gravitation. The branch of astronomy to which he devoted his subsequent life was the determination of the places of the fixed stars; and in knowledge of the instruments and methods necessary to be used, and sagacity in detecting and avoiding error, the opinion of those who are best able to judge places him second to none of his day. As a mere handler of instruments, his friend Troughton, one of the best of critics in such a matter, used to say that 'Mr. Pond had, within his knowledge, no equal or rival except Captain Kater.'

The circumstance which brought Mr. Pond into notice as an astronomer was the following:—when at Westbury, he became possessed of an altitude and azimuth circle by Troughton, and undertook a series of observations, from which he deduced (*Phil. Trans.*, 1806) that the quadrant then still in use at Greenwich for the determination of declinations had changed its form since the time of Bradley: a result which Troughton verified by actual measurement of the instrument. A mural circle (called Troughton's, from its maker) was accordingly ordered, in place of the quadrant; but it was not erected till 1812, when Mr. Pond, who had pointed out (or at least who had proved, for it had been suspected before) the error of the old instrument, was settled in his place at Greenwich. This circumstance would peculiarly connect his name with the mural circle (which from that time began to be looked upon as one of the essentials of an observatory), if other circumstances did not do this so much more fully, that the accident of his being the first Greenwich astronomer who used the instrument becomes comparatively insignificant. The memoir above cited says, 'Mr. Pond saw, almost intuitively, the vast superiority of this over every other form of the declination instrument, and for some years he and the artist who constructed it were perhaps the only persons who did clearly see and broadly assert that the operation of a circle did not depend upon having a bearing on each side, or a complete axis.' In 1825 the mural circle made by Mr. Jones, and intended for the Cape of Good Hope, was sent to Greenwich for examination. During this process Mr. Pond first used the two instruments for direct and reflected observations of the same star, a method which is thought to have been suggested by Troughton; and, at his request, the circle intended for the Cape was retained at Greenwich.* Mr. Pond is also the inventor of the method of observing in groups, described in the article CIRCLE (p. 189); and it is also to be noted that he was the very first astronomer who advocated what is now the universal practice, of depending upon masses of observations for all fundamental data.

In 1833 Mr. Pond had finished his standard catalogue of 1113 stars, which was then the largest of those which had any pretension to the same degree of accuracy. The controversy between Pond and Brinkley on the parallax of the fixed stars is a matter of history, on which it only concerns us here to say that the general opinion now is, that the former was right in his assertion that the latter did not prove the existence of a sensible amount of parallax. [PARALLAX.]

The works of Mr. Pond are: 1, the volumes of Greenwich Observations, published during his astronomership; 2, various Papers in the Transactions of the Royal and the Royal Astronomical Societies; 3, a Translation of the 'Système du Monde' of Laplace. His astronomical writings are condensed, and not addressed to any but those who have a thorough acquaintance with the subject. There is nothing of a popular nature in the usual work of an observatory; so that while few except astronomers knew more of the subject of this article than that one John Pond, Esquire, was noted in the almanacs and directories as astronomer royal, the following is the testimony of the Astronomical Society:—'It is not too much to say that meridian sidereal observation (which excludes the Herschelian branch of astronomy) owes more to him than to all his countrymen put together since the time of Bradley.'

PONDICHERRY, a considerable town on the sea-coast of the Carnatic, in Hindustan, formerly the principal seat of the French power in the East Indies, in 11° 57′ N. lat., 79° 54′ E. long., 85 miles south by west of Madras.

The first commercial expedition of the French which succeeded in reaching the East Indies by sea was composed of two vessels fitted out from a port in Bretagne (A.D. 1601); but the vessels were wrecked on the Maldive Islands before reaching their ultimate destination, and their commander returned ten years afterwards to France. A company of merchants sent out some vessels from a port in Normandy to Java (A.D. 1616 and 1619), but the success of this attempt was not such as to afford much encouragement. The next expedition was from Dieppe (A.D. 1633), where some merchants fitted out vessels and made several voyages. A company, established A.D. 1642, formed some settlements in Madagascar, but these in a few years dwindled almost to nothing.

In A.D. 1664, Colbert presented to Louis XIV. the plan of an India Company, which received the royal sanction. The first attempt of the new Company was to continue the settlements of Madagascar; but this attempt having failed, they turned their attention to the establishment of factories in Hindustan, and fixed the principal one at Surat on the coast of Gujerat (130 or 140 miles north of Bombay), at that time one of the largest and most commercial cities of Hindustan. Finding however that the competition of nations of more commercial character, and whose credit in the East was more firmly established, placed them at a great disadvantage, the French adventurers left Surat, and, supported by a strong squadron sent out from Europe, attempted to form an independent settlement at Trincomalee on the north side of Ceylon (A.D. 1672). From this place they were very soon driven by the Dutch, and sailing to the coast of the Carnatic, they took by assault the Portuguese settlement of St. Thomé, or Meliapoor, not far from Madras, from which they were again expelled (A.D. 1674), and the wreck of this unfortunate expedition took refuge at Pondicherry, a little town on the same coast, which they had purchased two years before (A.D. 1672), of the king of Visiapoor or Bejapoor. [BEJAPOOR.]

In following years they attempted to establish themselves in Siam, but the attempt failed (A.D. 1684-88), and they directed their chief attention to Pondicherry, which they strengthened with considerable fortifications. It was taken by the Dutch (A.D. 1693), but restored at the peace of Ryswick (A.D. 1697) with the fortifications greatly improved. The town at this period owed much to the wisdom and probity of M. Martin, its founder and subsequent governor. In the mean time the affairs of the India Company, by which the establishment had been formed, were going to ruin, through the mismanagement of those who directed it, the financial measures of the government, and the wars which were carried on near the close of the seventeenth and the beginning of the eighteenth centuries. In 1719 it was united with several other trading companies into one body, to which the government, influenced by the financial views of Law [LAW, JOHN], granted many privileges; but its affairs were conducted with little wisdom, except with regard to Pondicherry, the defences of which were further augmented. Dumas, who was sent out as governor, obtained from the court of Delhi the permission to coin money and the cession of the territory of Karical in the district of Tanjore.

---

* Here it remained until it was lately sent to its original destination. The direct and reflected observations are now made with one circle only.

During the government of Dumas, the nabob of Arcot was defeated and slain by the Mahrattas; and many of his family and subjects took refuge at Pondicherry, which was in consequence threatened by the victors; but the firmness of Dumas induced the Mahratta general to give up the enterprise and make a treaty with the French. About this time the French colony in Mauritius, or the Isle of France [MAURITIUS], was rising into importance under the care of La Bourdonnais; Bourbon had been colonised some time before [BOURBON]: both belonged to the India Company. The settlement of Chandernagore in Bengal, on the river Hoogly, 16 miles above Calcutta, was at the same time rising into importance under the management of Dupleix, who extended the commercial relations of the settlement in all directions. In 1742 Dupleix was removed to Pondicherry, and made director-general of the affairs of the Company in the East, which were at that time in their most prosperous condition.

In 1746 a French squadron, fitted out at the Isle of France by the activity of La Bourdonnais, arrived on the coast of the Carnatic, and having landed a considerable force, obliged Madras to surrender. But discord between Dupleix and La Bourdonnais injured the French interests, and the latter left the coast. Dupleix retained Madras, which La Bourdonnais had agreed to restore, and attempted, but without success, to capture Fort St. David, another English settlement. In 1748 Pondicherry was attacked by the English with a considerable fleet and army under Admiral Boscawen and Major Lawrence; but the siege was raised after several days, and the English retreated.

In 1749 Dupleix engaged in an attempt to raise two claimants, Mirzapha Jung and Chunda Saheb, to the offices of subahdar or viceroy of Deccan and of nabob of the Carnatic, by dispossessing the then occupants. The nabob of the Carnatic, An'-war-ad-dien, was defeated and slain, A.D. 1749, and the subahdar, though supported by the English, was killed by some traitors in his own army, with the encouragement of the French (A.D. 1750), and was succeeded by the claimant supported by Dupleix. Dupleix was appointed by the new subahdar governor of all the Mogul dominions on the coast of the Carnatic south of the river Kistna, in return for the aid he had given to his elevation. The claimant of the nabobship of the Carnatic was established as deputy of Dupleix at Arcot. An attack on Mahomed Ali, rajah of Trichinopoly, son of An'-war-ad-dien, was defeated by the intervention of the English, who sought to establish Mahomed as nabob of the Carnatic. The French resisted, and obtained support among the native powers, and severe but indecisive hostilities continued for some time. Negotiations were then tried, during which Dupleix was superseded, and a treaty was concluded which left Mahomed Ali nabob of the Carnatic (A.D. 1754). About this time the French had obtained of the subahdar of Deccan (Salabut Jung, brother and successor of Mirzapha Jung) the cession of an extensive line of coast in the Northern Circars; these by the treaty were to be given up, but the French appear to have retained them until, in the following war, they were expelled by the English.

In 1757 the war in the Carnatic was renewed: in 1758 the Count de Lally arrived at Pondicherry with strong reinforcements from France, and immediately attacked Fort St. David, about 16 miles south of that town, which he took by capitulation, and forced the English to abandon Devicottah, another of their posts. He next attacked the king of Tanjore, but unsuccessfully. Arcot and the black town of Madras were indeed taken, but Fort St. George (the fort of Madras) was relieved by an English fleet (1759), and Lally, with an exhausted commissariat and an empty paychest, retreated to Pondicherry. Subsequent hostilities were entirely to the disadvantage of the French; they were defeated at Wandewash, Arcot was retaken (A.D. 1760), and the English laid siege to Pondicherry, which surrendered early next year, and was subsequently demolished. The one or two posts which the French retained in the Carnatic followed its example; and Lally returned to Europe to perish by an iniquitous sentence on the scaffold.

At the peace of 1763 the French possessions in the Carnatic were restored. The management of the India Company, whose affairs were at a very low ebb, underwent considerable alterations. Some of their trading privileges were abolished, though in a few cases compensation was granted in the shape of an annual payment from the government or the parties benefited by the abolition. Subsequent changes (A.D. 1769) nearly annihilated the Company; its remaining privileges of exclusive trading were suspended; its vessels, the port of Lorient [LORIENT], and its Indian possessions, were given up to the government; which undertook, in return, the payment of most of the demands on the Company, and the creation of some perpetual annuities to meet the claims of the proprietors of the Company's stock.

In 1765 the rebuilding of Pondicherry was commenced, and in 1770 the population amounted to 27,000, almost entirely natives. But the superiority of the English in Hindustan was now decided. On the breaking out of hostilities between England and France in 1778, Pondicherry was taken by Sir Hector Monro after a gallant defence. The other French possessions were also seized; but some French officers and soldiers engaged in the service of Hyder Ali, and thus continued to oppose the power of England. In 1782 considerable armaments both from France and England arrived in India, and a body of 2000 French joined the troops of Hyder Ali. Several indecisive actions were fought by the hostile fleets under Suffrein and Hughes, and Trincomalee in Ceylon, which the English had just captured from the Dutch, was taken by the French; but Pondicherry and their other territorial possessions in India were not recovered till the peace of 1783. In 1793 they were again conquered by the English; restored by the peace of Amiens; again conquered in 1803; and again restored in 1814. The possessions of France in the East Indies now comprehend Pondicherry and Karical, with their dependencies on the Coromandel (or Carnatic) coast; Yanaon and its dependencies, with the factory of Masulipatam in the Northern Circars; Chandernagore and its territory, with Goretti and some other factories, in Bengal; and Mahé, and factories at Calicut and Surat on the western coast. They have also factories at Muscat and Mocha in Arabia. The island of Bourbon still belongs to the French: but Mauritius, or the Isle of France, has passed into the hands of the English. (*Malte Brun.*)

Pondicherry is built in a sandy plain not far from the shore, and consists of two parts, the white town and the black town. The white town is handsome; the streets are built with remarkable regularity, intersecting each other at right angles, and are of a uniform width. The houses are tolerably high, and have flat roofs; they are covered with stucco, white or yellow, and are adorned with fore courts or gardens. In the centre of the city is a spacious square planted with trees and laid out in walks, and open on the east side to the sea. The black town lies to the south of the white town, from which it is separated by a ditch or canal, with trees planted along the bank: it is laid out almost as regularly as the European quarter, but the houses are for the most part mere huts. Of the fortifications nothing remains but a brick tower, where the flag is hoisted. The French are debarred by treaty from restoring the fortifications, or from maintaining any force beyond what is necessary for the purposes of police. There are a government-house on one side of the square, a handsome building; a new bazaar, and at least two churches, one of them formerly belonging to the Jesuits' college, and the other to the Capuchin convent; the college buildings have been converted into a residence for the Catholic bishop and his clergy; the convent was destroyed by the English on the capture of Pondicherry in 1761. There is a grand pagoda in the black town, a building of vast size and grotesque architecture.

The population of the town and suburbs is computed to be 40,000. Trade is dull; the fiscal regulations of the British prevent the carrying on of any traffic with the interior. there is no harbour, but a tolerable roadstead. Indigo, sugar-cane, millet, dye and aromatic woods, and mulberry-trees are cultivated in the neighbourhood. The exports consist of rice, drugs, sugar, indigo, and blue linens. The imports are lace, and articles of dress, furniture, jewellery, and books. There are two courts of justice, a mint, a college, schools for whites and for blacks, a botanic garden, a mont de piété, or office for small loans, and several charitable institutions.

PONGO, an African word supposed to be corrupted from *Boggo*, and said to be applied indifferently to the *Chimpanzee*, the *Mandrill*, and the baboons of that country. Buffon appears to have been the first who used it to designate a gigantic species of *Orang-Utan*. Audebert restricts the appellation to the *Chimpanzee*. Wurmb first definitely applied the term to the *Pithecus Wurmbii*. Cuvier, together with most modern zoologists, follows Wurmb in this application. Mr. Swainson (*Classification of Quadrupeds*), speaking of *Pithecus*, says, 'This is the remarkable animal called *Pongo* by M. Wurmb; an ape, about whose natural station great diversity of opinion exists. M. Cuvier places it with the Oran-Outang; and expresses an opinion that the latter is merely the young. Illiger, on the contrary, considers it so closely allied to the baboons, that he calls it a *Cynocephalus*. From these opinions we may draw the inference that it is intimately connected with both, while subsequent information has incontestibly proved it is distinct from either. It is, in short, an ape with the aspect of a baboon.' We are of the same opinion with Professor Owen and others who take *Pongo* as the name or sign of the adult orang of the larger species, *Pithecus Wurmbii*.

PONIATOWSKI, STANISLAUS, COUNT, a Polish nobleman, born in 1678, who took the part of Stanislaus Leckzinski and of his protector Charles XII. of Sweden, against King Augustus and the Russian party, as it was called, in Poland. [Augustus II. of Poland; Charles XII. of Sweden.] He followed Charles in his adventurous expedition into Russia, with the rank of major-general in the Swedish army, and after the defeat of Pultawa materially helped the king to effect his escape with a handful of men into the Turkish territory. Having seen his master safely lodged at Bender, Poniatowski repaired to Constantinople as his agent, to forward his interests with the Sultan. He displayed in that difficult and dangerous mission all the resources of a most experienced diplomatist. Alone, without connections, the representative of a fugitive king, who was himself a kind of prisoner in the hands of the Turks, he contrived to engage the Porte to espouse the cause of Charles and to attack Russia, and he obtained influence enough to obtain the dismissal of several viziers in succession, for having thwarted his views.

The curious particulars of his negotiations at the Porte are related in a lively manner by Voltaire, in his 'History of Charles XII.' At last, when Charles resolved to quit Bender, Poniatowski followed his master into Germany, where he remained with Stanislaus Leckzinski, the protégé of Charles, who had been driven out of Poland by the Russian party. Poniatowski remained with Stanislaus till the death of Charles, when all hopes of seeing him restored to the crown of Poland having vanished, Poniatowski made his submission to King Augustus, who not only restored to him his property, but made him treasurer of Lithuania, general of the guards, and lastly, palatine of Masovia. After the death of Augustus he endeavoured to effect the restoration of Stanislaus Leckzinski, but did not succeed, and the elector of Saxony was elected king. [Augustus III.]

Poniatowski made his submission to the new king, who took him into favour, and made him, in 1752, castellan of Cracow, which was one of the highest dignities in the kingdom. Some time after he retired to his estates, where he died in 1762. He married a Princess Czartoriska, by whom he had two sons, one of whom became afterwards king of Poland [Stanislaus Augustus], and the other entered the Austrian service and became lieutenant-general of artillery.

PONIATOWSKI, JOSEPH, PRINCE, born at Warsaw, in 1763, was the son of Andreas Poniatowski, lieutenant-general of artillery in the Austrian service, and nephew to Stanislaus Augustus, the last king of Poland. He entered the Austrian service, and became colonel of dragoons and aide-de-camp of the emperor Joseph II., with whom he made a campaign against the Turks in 1787. In 1789 he returned to Poland, where he showed himself a warm supporter of the independence of his country. He fought against the Russians in 1792, but was obliged to resign his command in consequence of the king's weakness and partiality for Russia. In 1794, when the Poles again rose against the Russians, Joseph Poniatowski served under Kosciusko, but Kosciusko being defeated, he was obliged to emigrate, and he retired to Vienna.

In 1798 he returned to Warsaw, which was then under the dominion of Prussia, and the Prussian government restored to him part of his estates, where he spent several years. After the battle of Jena, in 1806, and the invasion of Prussia by Napoleon, the French armies advanced towards the Vistula. In this crisis he was appointed by the king of Prussia military commander of Warsaw, where he formed a national guard for the security of the city. In this capacity he received the French general Murat, who took possession of Warsaw, in November, 1806. At first he would not accept any service under the French, until Napoleon, having arrived at Warsaw, cajoled the Poles with fine though vague promises, talking, in his own oracular style, of 'the destinies of Poland being on the eve of being fulfilled,' &c. The Poles trusted to him, and a national army was formed, of which Poniatowski took the command, and which rendered great services to the French during the campaign of 1807 against the Russians. By the peace of Tilsit, Russia and Austria retained the greater part of Poland, and the duchy of Warsaw was given to the king of Saxony. Poniatowski remained minister at war for the duchy, but the Polish army was scattered among the French garrisons in Germany, and some regiments were drafted for service in Spain. When a new war broke out between Austria and Napoleon in 1809, Poniatowski, who had only a small force left with him, after fighting against the Austrians, was obliged to evacuate Warsaw, but he soon after invaded Galicia, and called the inhabitants to arms.

By the peace of Vienna (October, 1809), Galicia was taken away from Austria and united to the grand-duchy of Warsaw. When the war broke out between France and Russia in 1812, Poniatowski, who had in the mean time increased and disciplined the Polish army, obtained the command of the fifth corps of the 'grand army,' which was composed entirely of Poles. He fought bravely in several battles against the Russians, and entered Moscow with Napoleon. At the same time he maintained the strictest discipline in his corps, which did not share in the excesses committed by other portions of the invading army. In the disastrous retreat from Moscow the same corps distinguished itself by its orderly behaviour. Being obliged to evacuate Warsaw, Poniatowski withdrew into Saxony, and in the following campaign of 1813 Napoleon gave him the command of a mixed corps of French and Poles. He fought with his usual bravery in various battles, and was made a marshal of France by Napoleon just before the battle of Leipzig. A few days after, on the 18th of October, while protecting with a handful of men the retreat of the French, he was twice wounded, and being pressed by the enemy upon the banks of the river Elster, which was swelled by the rains, he spurred his horse into the river and disappeared in the water.

Joseph Poniatowski was not only an able and brave officer, but he was also a man of strict and upright principles, and his integrity was well known. Less confiding than most of his countrymen in the promises of Napoleon, he followed, from a sense of duty to his country, what he conceived to be the only chance left of regaining its independence. Joseph Poniatowski left no children.

PONS. [Charente Inferieure.]

PONS VAROLII. [Brain.]

PONT-A-MOUSSON. [Lavoro, Terra di.]

PONTE. [Bassano.]

PONTEFRACT, an antient borough, a market-town, township, and parish in the upper division of the wapentake of Osgoldcross, in the honour or liberty of Pontefract, and in the West Riding of Yorkshire. By the Reform Act the borough includes Ferrybridge, the castle precincts, Pontefract Park, and the townships of Tanshelf, Monkhill, Knottingley, and Carlton. These places, with the exception of Pontefract Park, which is extra-parochial, form the parish of Pontefract, contain nearly 10,000 inhabitants and send two members to parliament. The parish extends over 7790 acres. Pontefract Park comprises 1300 acres. The municipal borough is still confined to the township of Pontefract, and has four aldermen and twelve councillors. The honour of Pontefract belongs to the crown, as part of the Duchy of Lancaster; it has local courts, and a debtors' gaol. The Court Baron for the recovery of debts under five pounds is held at Pontefract once in three weeks, and by adjournment from thence, at Huddersfield, Bradford, Leeds, and Barnsley. The debtors' gaol is at Rothwell. Pontefract is 173 miles north-north-west of London, and twenty-four miles south-south-west of York.

This town is of great antiquity, and of considerable historical importance. Its origin and the etymology of its name are alike unknown. The legends of antient historians and the conjectures of those of later date are equally unworthy of notice. According to Camden its name was changed to Pontefract by the Romans. The place was called Kirkby in the time of the Saxons, and it is not improbable that it was one of the first places in England at which a church was erected and Christianity preached.

After the Conquest, Ilbert de Lacy received a grant of the place; in the tenth year of William, his vast possessions were confirmed to him. Soon after he began to build his castle, which partook of the features of castle, fortress, and palace. He is said to have called the name of the town *Pontfrete*, from some fancied resemblance to a place so called in Normandy, where he was born. The castle was built on an elevated rock, and it had a most extensive and picturesque view of the surrounding country. It was not commanded by any contiguous hill, and could only be taken by blockade. The wall of the castle yard was high, and flanked by seven towers. A deep moat was cut on the western side, where were also the barbican and drawbridge; there were other gates, which might be used as watch-towers, and some of them were protected by drawbridges. The dungeons were of a frightful nature. The area covered and enclosed by this immense building was about seven acres. [BRADFORD.]

Ilbert de Lacy was a great favourite with William, and received from him as a reward for his adherence and services one hundred and fifty manors in the west of Yorkshire, ten in Nottinghamshire, and four in Lincolnshire. These vast possessions were confirmed to his son Robert, called Robert de Pontefract, by William Rufus; they descended from him to his son Ilbert, and continued in the family till 1310, when Henry de Lacy, having no male children, left his estates to his daughter Alice, who was married to Thomas, earl of Lancaster, uncle to Edward II. In the quarrels between that weak-minded prince and his nobles, the Earl of Lancaster acted a very conspicuous part. He was taken prisoner with many other barons, and brought to Pontefract Castle, which had fallen into the hands of the royal army. Here he was imprisoned for some time, tried by his peers, some of whom were his mortal enemies, was convicted without being heard in his own defence, suffered many indignities, and was afterwards hurried away to execution. He obtained the favour of dying on the block, whilst the barons who were his adherents were hanged. Pontefract Castle was afterwards the scene of Richard II.'s imprisonment and death; but whether he was murdered or starved to death has not hitherto been satisfactorily decided. Here the Duke of Gloucester, afterwards Richard III., shed the blood, without any legal trial, of Anthony Woodville, Earl Rivers, Richard lord Grey, Sir Thomas Vaughan, and Sir Richard Hawse, in order to make more easy his accession to the throne. In the reign of Henry VIII. the fortress surrendered to the famous Robert Aske, captain-general of the Pilgrims of Graco; and during the civil wars between Charles I. and the parliamentarians the castle was frequently besieged and defended by both parties. The garrison, after having been reduced from 600 men to 100, surrendered, in 1649, to General Lambert, having first proclaimed Charles II. successor to the throne of his father, and done all to defend it that a garrison of brave men could do. Shortly after it was dismantled by order of parliament, and all the valuable materials were sold.' For 600 years the castle of Pontefract was the ornament and terror of the surrounding country; at the present day little even of its ruins remain. The area is now chiefly occupied by gardens, and a quarry of filtering-stones, which are in great request in all parts of the kingdom.

The parish church of Pontefract, dedicated to St. Giles, is small, and has no great pretensions to notice. The more antient church of All Saints, the original parish church, is in the form of a cross, with a handsome tower in the middle: it is mentioned by Rickman as deserving of attentive examination. This church probably dates as far back as the time of Henry III.; it is altogether in the style of that period The other places of worship are the Roman Catholic chapel, the Friends' meeting-house, and the Independent, Wesleyan, and Primitive Methodists' chapels.

The town has a subscription library, a mechanics' library, and a news-room. The free grammar-school was established in the reign of Edward VI.; it fell into neglect, and was complained of to the chancellor of the duchy in the 6th Elizabeth, and again about a century afterwards. It was re-chartered in 1792, by George III., and placed under the visitorial control of the chancellor of the duchy of Lancaster. It is one of the twelve schools that send candidates for Lady Elizabeth Hastings's exhibitions at Queen's College, Oxford. The master is allowed to take boarders.

The other charity-school of Pontefract is now merged in the national school; it has an endowment of 85*l.* a year, and receives ten guineas a year from the charity of Lady E. Hastings. This income is again augmented by annual subscriptions. 'When the king's grammar-school was re-founded in the reign of George III., the trustees of this charity (the charity-school) appropriated 150*l.* from its funds towards the erection of the said grammar-school.' (Boothroyd's *Pontefract.*) The British school, which is supported by small payments from the children, and subscriptions, was commenced in 1831, and re-established in 1837; the theatre having been purchased and divided into two rooms capable of accommodating 400 pupils of both sexes. The town-hall is a handsome building, which was erected on the site of the old moot-hall, at the joint expense of the county and the corporation; the borough and petty sessions are held in it. The spring quarter-sessions are held in the court-house during the Easter week, a commodious modern building, which was built at the expense of the West Riding. The gas-works were constructed in 1832, at an expense of 4200*l.* The races, formerly held yearly in September, are extinct; the course occupies a portion of the park district. There are at Pontefract a number of endowed alms-houses or hospitals, which mostly bear the name of their founders; they afford the usual benefits, and are open to the common objections made to such charities. The market is held on the Saturday, and is well supplied, and there are eight annual fairs for the sale of cattle. The general aspect of the town is neat, airy, and spacious; it is chiefly celebrated for its extensive gardens, nurseries, and liquorice-grounds; its soil is rich and deep. Great quantities of vegetables are supplied by Pontefract to Leeds, Wakefield, and other populous towns in the county. (*Communication from Yorkshire.*)

PO'NTIFEX was the name by which the Romans designated the members of the most illustrious of their great colleges of priests. The pontiffs are said to have been instituted by Numa Pompilius for the purpose of taking care that the laws relating to religion should be observed by individuals as well as by the state. Their original number, according to Livy (x. 6), was four, two for each of the tribes of the Ramnes and Tities. Cicero (*De Rep.*, ii. 14) says that their number was five, but he includes the Pontifex Maximus, or chief pontiff.

The minor pontiffs were a college of priests of which scarcely anything is known: Cicero mentions three members of it (*Harusp. Resp.*, 6), and Niebuhr (*Hist. of Rome*, i. note, 775) supposes that it belonged to the Luceres, who had no representative in the great college of pontiffs. The name of the minor pontiffs was afterwards transferred to the secretaries of the other pontiffs (pontifices majores: Liv., xxii. 57; Capitolin., *Vit. Macrin.*, 7).

When the great state-offices had become accessible to the plebeians, they also obtained the privilege of being represented in the college of pontiffs by members of their own order. This change was brought about in 300 B.C. by the Ogulnian law, by which the original number of pontiffs, through the addition of four plebeians, was increased to eight, or, including the chief pontiff, to nine. (Liv., x. 6, 9.) The chief pontiff however continued to be taken from the patricians to the year 254 B.C. (Liv., *Epit.*, xviii.) This number remained the same for more than two centuries, until in 81 B.C. the dictator Sulla raised it to fifteen. (Liv., *Epit.*, 89.) J. Cæsar added one more pontiff. (Dion Cass., xlii., p. 236.) In the early ages of the history of Rome the pontiffs were elected by the kings, but after the overthrow of the kingly power the college exercised the right of co-optation (Dionys. Hal., ii. 73; Livy, xl. 42), until 104 B.C., when the right of electing persons to the office of pontiff was partly transferred to the people by the Domitian law; for, according to this law the co-optation of the college was still necessary as a religious ceremony, after a person had been elected by the people. (Cic., *in Rull.*, ii. 7.) When Sulla increased the number of pontiffs, he at the same time gave back to the college the full right of co-optation; the tribune Labienus indeed, in 63 B.C., revived the Domitian law, but it was again abolished by Antony. (Dion Cass., xliv., p. 305.) The chief pontiff, who at first seems to have been appointed by the kings, was afterwards elected by the curies in the comitia curiata, and generally taken from the number of the pontiffs themselves, or from those who had held the highest offices of the state. (Liv., xl. 42, comp. with xxv. 5.) The functions of the college of pontiffs were not limited to the service of any particular deity. It had very extensive powers, and not only had the superintendence over all matters of religion, but even those which were in any degree connected with it, such as marriage, adoption by adrogation (Cic., *Pro Dom.*, 13), and funeral ceremonies. They had a direct judicial power, and might in some instances even punish with death. (Cic., *De Legg.*, ii. 9; comp. with Liv., xxii. 57.) The chief pontiff, whose office, like that of the other pontiffs, was for life, and who was not responsible either to the senate or the people, was supreme judge in all matters relating to or connected with religion, and from his sentence an appeal could only be made to the people in cases where a magistrate was fined or his person seized (Liv., xl. 42); for the few instances of later times where a tribune interposed and modified the sentence of the chief pontiff seem to have been anomalies. His powers extended over magistrates as well as private individuals; and the former, if acting contrary to the laws of religion, might be fined (Liv., xxvii. 51; Cic., *Philip.*, xi. 8; Liv., xl. 42), or compelled by the chief pontiff to resign their office. It also formed part of his duties to regulate the calendar, and to interpret the ceremonial laws, for he and his college were in the exclusive possession of the ritual books (commentarii sacrorum or libri pontificales), in which all religious rites were laid down, and which at all times were considered as decisive upon any point which belonged to their jurisdiction. The rules and regulations which guided the pontifices formed a large body of law, called 'Jus Pontificium.' (Cic., *De Or.*, i. 43; iii. 33; *Pro Dom.*, 13.) The oath tendered to a newly elected pontiff, not to profane the sacred rites by any untimely publication, most probably referred to these books. (Dionys. Hal,. ii. 133.) The chief pontiff had moreover to keep a kind of state archive (the commentarii pontificum, annales pontificum, or annales maximi), in which he recorded the memorable events of every year, and which were exhibited at his house for the inspection of the people. The assemblies of the curies could only be held when the pontiff had no religious grounds for preventing them, and their presence was indispensable at these meetings. (Gellius, v. 19; Dionys. Hal., ix. 41, comp. with x. 32.) Among the external distinctions of the pontiffs, were the toga prætexta, and the tutulus or galerus, a cap of a conic form adorned with an apex. They lived in public buildings on the Via Sacra (Suet., *Cæs.*, 46), or in the house of Numa (Plin., *Epist.*, iv. 11). The chief pontiff was not permitted to quit Italy (a rule first violated by P. Licinius Crassus); he was not allowed either to see or to touch a corpse, or even to visit a house in which there was a dead body. After the death of his wife, who, according to the laws, should always be a woman of great moral virtue, he was not permitted to marry again. (Plin., *Paneg.*, 83.) He also elected the vestal virgins, and superintended their moral conduct. From the time that Augustus assumed the office of chief pontiff, it was held by all his successors down to the time of Gratianus, who disdained this dignity. (Zosim., iv. 36, 9.) The title P.M., or PON. M., Pontifex Maximus, appears on some of the coins of the Roman emperors. [CALIGULA.] The mode of living of the Roman pontiffs does not seem to have been much more sober or simple than that of some priests of modern times. (Horat., *Od.*, ii. 14, 26, ff.; Martial, *Epigr.*, xii. 48, 12; Macrob., *Sat.*, ii. 9.)

PONTIUS PILATE. [PILATE, PONTIUS.]

PONTIVY. [MORBIHAN.]

PONTOISE. [SEINE ET OISE.]

PONTOON, or PONTON. This term is employed by the French to signify any barge or flat-bottomed boat; but in this country it is confined to those vessels which are used in the formation of floating-bridges for military purposes.

The conveyance of an army with its artillery and baggage across the rivers which intersect its line of march is one of the most difficult as well as the most important operations in military tactics. The occupation of an advantageous position in a given time, when the army acts offensively, materially influences the success of a campaign; and the favourable moment may be lost, if means should not be at hand to overcome the obstacle presented by a deep and rapid stream. But the failure or insufficiency of such means must be attended with the most fatal consequences to a retreating army, when it is prevented by a river from getting beyond the reach of an enemy; for its safety, in this case, depends upon the power of passing the river without delay, and upon the removal or destruction of the bridge immediately afterwards.

History presents us with innumerable instances, both of the ruin of armies caused by the want of means to make good their passage across rivers, and of the protection which armies have received when rivers have interposed between them and the superior forces of an enemy. To take an example from modern warfare, it may be observed, that during the retreat of Napoleon from Moscow, had it not been for the extraordinary care used by the chief of the French engineers to preserve the materials requisite for the formation of a bridge, the whole of the army must have been captured or destroyed on the banks of the Beresina.

The rapidity of warlike operations seldom allows bridges, at least those of considerable magnitude, to be constructed on piles or piers; and perhaps the only military work of this nature which need be hinted at is that which was formed by Cæsar across the Rhine. [BRIDGE.]

Bridges consisting of timber platforms supported on floating vessels appear to have been in use in all ages. But those which were thrown by Darius across the Bosporus, and subsequently over the Danube, and that which was formed by the order of Xerxes over the Hellespont at the time of his unfortunate expedition into Europe, deserve to be considered as the most famous works of that nature which were constructed by the antients: and Herodotus, who has preserved (lib. iv., 88) the name of the Greek engineer employed on the two first, has also given a full description of the last (vii. 36). He states that 360 vessels, anchored both at the head and stern, were disposed in parallel directions across the strait with their keels in the direction of the current, in order to diminish the strain on their cables; and that parallel to this line, but nearer the Archipelago, was another consisting of 314 vessels, similarly disposed. The vessels were connected together by cables, over which was laid a platform of planks covered with a bed of earth, and there was a rail on each side. Xenophon also relates (*Anabasis*, lib. ii., c. 4) that the Greeks, in their retreat, passed the Tigris by means of a bridge which was supported on thirty-seven vessels. Of such boat-bridges for military purposes the most remarkable, in modern times, is that which was formed, by the engineers of the British army, across the Adour, in the south of France, in 1814. It consisted of 25 chasse-marées, varying in burthen from 20 to 40 tons, which were moored at distances of nearly 40 feet from centre to centre. At first, hawsers resting on their decks were strained by capstans and made fast to some heavy guns which were laid behind the retaining walls on the sides of the river, and these ropes carried the planks which formed the roadway; but after a few weeks they were removed, and replaced by timbers, which from their steadiness were found preferable. The breadth of the river at the place where the bridge was formed is 810 feet, and booms were moored across, both above and below the bridge, for its protection.

The precise period at which pontoons, or flat-bottomed vessels, were first employed to support a bridge is unknown. Folard observes, in his observations on the fifth book of Polybius, that for passing rivers the Germans in his time used vessels formed of timber frames covered with leather: he adds that the Dutch troops had pontoons of wood covered with tin, and that the French took some of them at the battle of Fleurus, which was gained, in 1698, by the Maréchal de Luxembourg over the Prince of Waldeck. Mention is frequently made of pontoon-bridges, both in Germany and Italy in the beginning of the eighteenth century, particularly during the campaigns of Marlborough; and, from the speed with which they are said to have been executed when required, it is probable that a corps of men was then particularly employed in that branch of service.

The pontoons employed during the late war differed but little from those used in the times above alluded to: they were from 17 to 21 feet long; from 4 to 5 feet broad, and from 2 feet to 2 feet 3 inches deep. In the formation of the bridge, a rope was tightly stretched across the river; the vessels were then rowed to their places, and each was made fast at one end to the rope; another rope was then stretched across the river, parallel to the former, at the opposite ends of the pontoons, and to this rope those ends were made fast. When a strong current set obliquely across the river, the sides of every two pontoons were sometimes connected together by rope braces stretched diagonally across the intervals, in order that the effect of the current upon each might be counteracted by a like effect on the next; and, in very rapid streams, anchors were also thrown out from each or from every second or third pontoon according to circumstances.

Timber-baulks, or joists, were then laid from the shore to the first pontoon, from that to the next, and so on, at intervals from each other depending upon the breadth of the bridge or the weight to be supported. Every two in the direction of the length were attached together by a bolt, which allowed the bridge to yield to the rise or fall of the water. Above these timbers were placed the chesses, or flooring-planks, close together and perpendicular to the length of the bridge; and these were kept down by a riband or a plank, which was fastened over their extremities on each side of the bridge.

Colonel Pasley, to whom the department of military engineering in the British service is so much indebted for the improvements which he has introduced into every branch of art connected with practical fortification and siege operations, has for many years devoted particular attention to the subject of military bridges. The form of the old pontoons rendering them difficult to manage in the water, and their great weight, when it was necessary to transport them from place to place by land, causing them to be a serious encumbrance to an army on its march, that officer was led to construct the pontoons in the form of canoes, with decks, each end being shaped like the head of a boat, in order that they might be easily moved through the water by rowing, with either end foremost. They are constructed of light timber frames, covered, except the deck, with sheet copper; and each vessel is formed in two equal parts by transverse partitions, so that the demi-pontoons may be separated from each other when the bridge is to be conveyed on carriages by land with the army. When in the water, the parts are connected together by a rope, which passes through two perforations in the keel, near the place of junction, and by a rectangular frame of wood, which is laid along the deck, and attached to it by lashings. Each half-vessel is also divided into two compartments by a partition; and small pumps are provided, by which the pontoon may for a time be kept afloat, should a hole be made in its side by a shot or by any other accident.

Sir James Colleton, some years since, invented pontoons of wood of a cylindrical form, some of which have been occasionally employed in experimental operations; and cylindrical pontoons of tin, which were subsequently invented by Major (now Colonel) Blanchard, have lately been introduced into the service. These last have hemispherical ends, and are divided both longitudinally and transversely into several compartments by partitions of tin, both to increase their strength and to prevent them from sinking in the water in the event of their being accidentally perforated in any part. They possess the advantages of great lightness and buoyancy; but they have not the durability of copper vessels, and they must be very liable to be injured when transported by land, particularly if a march should take place under a hot sun. Some of Colonel Pasley's copper pontoons are said to have been in use above 18 years.

In 1836 the comparative merits of Colonel Pasley's and Colonel Blanchard's pontoons were tried upon the Medway, when large bodies of infantry and cavalry, besides three pieces of artillery, were made to pass over the river on bridges supported by vessels of the two kinds. The order of march was purposely such as to subject the bridges to the severest strains; and a superiority of steadiness on this occasion appears to have led to a preference in favour of the pontoons proposed by the last-mentioned officer.

The breadth and depth of one of Col. Pasley's pontoons are 2ft. 8in. The diameter of one of Col. Blanchard's cylinders is 2ft. 6in. The length of each kind of pontoons is 22 feet.

The manner of forming the bridge, with both kinds, is nearly the same. A rectangular frame, whose length is about equal to the breadth of the platform for the intended bridge (12 feet), is laid down longitudinally on the deck of the canoe, or on the surface of the cylinder, and is kept in its place by rope lashings; on the upper surface of this frame, in the direction of its breadth, are nailed pieces of wood in pairs, at equal intervals; the distance between every two in each pair being little more than equal to the breadth of a baulk, or joist (2½ inches), one extremity of which is to be received between them, and the number of pairs being equal to the number of baulks which are to support the chesses or planks forming the roadway. A raft is formed with two of these pontoons, by placing them parallel to each other, at a distance, from centre to centre, equal to about 12½ feet; the ends of two baulks, or transoms, as they are called, are made to rest upon the frames before mentioned, the distance between them being equal to the intended breadth of the bridge, and they are kept steady by having near each extremity a hole bored through them, into which enters an iron pin fixed vertically for the purpose in the frame: they are also made fast to the pontoons by ropes passing through rings on the decks. Three or more baulks are then laid down parallel to the transoms, with their extremities confined between the cross-pieces nailed to the frames as abovesaid: the chesses are laid close together above them, and their ends are kept down by ribands, which are attached to the transoms by lashings passing over them, and under the latter, at intervals. In those ribands are fixed rowlock pins, and, when the bridge is not formed, the ribands being then placed parallel to the lengths of the pontoons, at the sides of the raft, the latter may be moved on the water by the oars.

When the bridge is to be formed, a certain number of such rafts are rowed to their stations in a line across the river, the lengths of the pontoons being parallel to the banks, and there anchored; the distances between the nearest pontoons in two rafts being equal to that between the two pontoons in each raft. Then each raft carrying the materials which are to make a platform over the water between itself and the next, such platform is laid down in a manner similar to that which is employed in laying down the platform of the raft; and from each of the extreme pontoons a like platform is extended to the shore of the river.

When the banks are favourable, the complement of men attached to each raft of two pontoons, namely 1 non-commissioned officer and 6 privates, can dismount two vessels and their stores from the carriages, launch them, and form the raft in a quarter of an hour. All the rafts being put together at the same time, the whole bridge may be formed in another quarter of an hour. After the passage has been effected, the bridge can be dismantled in eight minutes, the rafts can then be taken to pieces, and the vessels and stores re-packed on the carriages in a quarter of an hour.

In order to convey the pontoons with an army, each is placed, with all its accompaniments, on a four-wheeled carriage. Col. Pasley however is enabled to use only a cart with two wheels for each pontoon; the latter being separated into two demi-pontoons, which are placed side by side above their stores. The shortness of these carriages enables them to be turned within a smaller space than would be required for a four-wheeled waggon.

The inconvenience attending the transport of pontoons, or the necessity of passing a river when they are not at hand, has induced commanders of armies to have recourse to bridges supported on rafts of timber or on empty casks, which in Europe can always be procured. Each raft may consist of four or more rough trunks of trees lashed together, and may be retained in its place by anchors, or by being made fast to a rope stretched across the river: the baulks and chesses are applied as in a pontoon bridge. Perhaps the greatest raft-bridge ever formed is that which was executed by General Sokolniki over the Niemen at Grodno, in 1792. Trunks of trees from fifty to sixty feet long, and from twenty to twenty-eight inches in diameter, were united by tens, and every ten were bound together at both ends by transverse braces, so as to form a raft, which, as all the large ends of the trees were placed contiguously, resembled the voussoir of a bridge. All the voussoirs, fifty-seven in number, were placed in the river, side by side, in an arc of a circle having its convexity towards the upper part of the river; and a sort of key-voussoir was formed by a vessel 116 feet long and 22 feet wide, which was moored in the river where the current was the most rapid. Baulks and planks were placed, as usual, above the rafts to form the road. The breadth of the river at that place is about 1080 feet. (Berard, *Equilibre des Voûtes.*)

A strong raft-bridge was formed by the Russians and Prussians over the Elbe near Dresden, in 1813: one course of logs disposed parallelwise to each other formed the bottom of each raft; cross-timbers were laid above these; and over them was a third course of timbers, each placed above the interval between two of those below it. The timbers were well lashed together; a strong cable was stretched across the river on each side of the bridge, which was further retained in its place by anchors, and a road was formed of planks as usual. While the British army was serving in Spain during the late war, the roofs of buildings were occasionally taken to form rafts: the rafters served as baulks; and, for want of nails, the planks were kept down to the timbers by ribands formed of young trees split in two longitudinally and tied by willow twigs.

A cask bridge is sometimes formed in the following manner:—a certain number of casks are placed side by side, so as to form a sort of floating pier, having their axes in horizontal positions; the casks are lashed to two gunwale timbers, as they are called, which extend along the upper side of the pier at the extremities of the casks; two of these piers are placed at an interval of about ten feet from each other, and they are connected together by the baulks which support the platform. As many of these rafts are prepared as may be necessary, they are rowed to their places in the line, and the bridge is formed in the same manner as the pontoon-bridge above described.

When the formation of a bridge extending over a river from one bank to another becomes impossible, numerous expedients are had recourse to for conveying troops across by means of what are called flying or moving bridges. We learn from Arrian that the army of Alexander passed the Indus by means of boats and rafts of timber, the latter being supported on bags made of skin and inflated with air; and in a similar manner the infantry of Hannibal is said by Livy to have crossed the Rhine. In India, at the present time, the passage of rivers is often effected by means of basket-boats, which are formed of split bamboos and covered with half-dressed hides. Each vessel is said to be capable of containing about thirty men.

In 1811, Capt. Squires, of the Engineers, formed a bridge over the Guadiana by fixing trestle-piers in the shallow parts of the river and mooring boats in the middle; but just as the bridge was finished, the river swelled and carried away the trestles. The boats were then converted into flying bridges, to convey over the cavalry and artillery; and a slight narrow bridge was made for the infantry with pontoons and casks, the latter being taken from the neighbouring villages.

For many interesting particulars relating to the passage of rivers in military operations, see Sir Howard Douglas's *Essay on Military Bridges*, second edition.

PONTO'PHILUS, Dr. Leach's name for a genus of Shrimps (*Egeon*, Risso).

PONTO'PPIDAN, ERIC, born at Aarhuus in Jutland, was the son of Louis Pontoppidan, a clergyman who wrote several ascetic works, besides a 'Theatrum Nobilitatis Danicæ, in quo familiæ illustrium heroum, aliorumque genere ac virtute excellentium virorum genealogia, recensentur,' 2 vols. fol. Eric studied at Fredericia, and afterwards at Copenhagen, where he took his degree in divinity. He was afterwards preceptor to several young noblemen, with whom he travelled; and subsequently he was appointed minister of a country parish in Holstein, and in 1735 he was numbered among the king's chaplains. In 1738 he was appointed to a chair of theology in the university of Copenhagen; and in 1747 he was made bishop of Bergen in Norway. He was the author of numerous works, both in Danish and Latin, upon historical, religious, and antiquarian subjects. The principal are:—1, 'Theatrum Daniæ veteris et modernæ,' 4to., 1730, being a description of the geography, natural history, antiquities, &c. of the kingdom of Denmark. The author afterwards treated the same subject at much greater length in a work written in the Danish language. 2, 'Den Danske Atlas,' in 7 thick vols. 4to., most of which were published after his death, and which give a complete and elaborate topographical description of Denmark, accompanied by maps, views, and plans of the various towns, engraving of curious coins, inscriptions, monuments, costumes, and other remarkable objects, with an introduction to the history of the country, the genealogy of its kings, and other particulars relative to its history. 3, 'Gesta et Vestigia Danorum extra Daniam,' 2 vols. 8vo., 1740. In this work Pontoppidan gives the history of the old Danish race; its migrations to Britain, France, and other countries; the exploits of its warriors, &c. In his narrative the author is considered as having allowed himself to be carried by national feelings beyond the bounds of critical discrimination. 4, 'Annales Ecclesiæ Danicæ,' 4 vols. 4to., a good history of the church of Denmark. 5. 'Marmora Danica selectiora,' in fol., in which the author copies a number of inscriptions of various ages, which elucidate the history of his country. 6, 'Det förste forsög paa Norges naturlige historie,' 4to., 1752, being an essay on the natural history of Norway, translated into English in 1755; a curious work, but exhibiting marks of considerable credulity, especially concerning the enormous sea-serpents, the kraaken, and other fabulous monsters. 7, 'Memoriæ Hafniæ,' a good description of the city of Copenhagen. 8, 'Origines Havnienses,' a history of the same city. 9, 'Glossarium Norvegicum,' or collection of obsolete words in that language, Bergen, 1749. 10, 'A Manual of Religion, in Danish, or Explanation of Luther's Catechism,' a work which has been translated into German and Icelandic, and is used in schools throughout all the Danish monarchy.

Pontoppidan died at Bergen, in 1764. His relative, Christian Joachim Pontoppidan, published two good maps of Norway in 1785 and 1795.

PONTUS, a country of Asia Minor, derived its name from the expression 'on the Pontus Euxinus' (ἐν Πόντῳ), and was used rather as a political than a geographical division of country. Under Mithridates the Great it included the whole of Paphlagonia and part of Bithynia; but the name is usually applied to the country between Colchis and the river Halys, and is consequently bounded on the west by Paphlagonia, on the south by Cappadocia, and on the east by Colchis. The boundary between Colchis and Pontus is differently given by different writers; Ptolemy places it as far as the Phasis, and Strabo at Trapezus. (Strabo, xii., p. 548.) On the south Pontus is separated from Cappadocia by a lofty range of mountains called Paryadres. The north-eastern part of Pontus is exceedingly barren, and was inhabited by various barbarous tribes, of whom Xenophon has given some account in the 'Anabasis.' The western part of the country, which is very fertile, is well drained by the Iris (*Yeshil-ermak*) and the Thermodon (*Thermeh*), and affords good pasture for numerous flocks. The district of Phanarœa was considered the most fertile part of Pontus, producing wine, oil, and many other things. (Strabo, xii., p. 556.)

The name of Pontus, as a separate kingdom, does not occur either in Herodotus or Xenophon. In the time of those writers the country appears to have been inhabited by various independent tribes; it was first erected into a separate kingdom by Ariobarzanes I., about the beginning of the fourth century before the Christian æra. According to the concurrent testimony of several antient writers, Ariobarzanes was descended from one of the seven Persian chiefs who overthrew the Magi, B.C. 521. (Florus, iii. 5; Diod., xix. 40; Polyb., v. 43.) Ariobarzanes was succeeded by Mithridates I., and Mithridates by Ariobarzanes II., B.C. 363; but it was not till the reign of Mithridates II., who succeeded Ariobarzanes, B.C. 337, that the kingdom of Pontus acquired any degree of political importance. In the troubles which followed the death of Alexander the Great, Mithridates was enabled to extend greatly his paternal dominions, whence he is frequently called the founder (κτίστης) of the kingdom of Pontus. [MITHRIDATES II.] Mithridates died B.C. 302, and was succeeded by his son Mithridates III., who died B.C. 266, leaving the crown to Ariobarzanes III., who expelled from the country, in conjunction with the Gallo-Græci, an Egyptian force sent by Ptolemy. Ariobarzanes III. was succeeded by Mithridates IV., who died about B.C. 190, leaving the crown to his son Pharnaces I. Pharnaces conquered Sinope (Strabo, xii., p. 545), and carried on war against Eumenes II., king of Pergamos. Pharnaces was succeeded by Mithridates V., surnamed Euergetes, and the latter by his son Mithridates VI., surnamed Eupator, B.C. 120. The war of Mithridates with the Romans, which ended in B.C. 63 by the conquest of Pontus and the death of Mithridates, is given under MITHRIDATES VI.

Pharnaces II., the son of Mithridates, who had deprived his father of the throne, was rewarded for his treachery with the kingdom of the Bosporus and the title of an ally of the Romans. (Dio., xxxvii. 14; Appian, *Mithr.*, c. 113.) The greater part of the kingdom of Pontus was annexed to the Roman province of Bithynia, and the remainder was given to Deiotarus, tetrarch of Galatia. In the civil wars between Pompey and Cæsar, Pharnaces attempted to obtain his hereditary dominions in Pontus, but he was defeated by Cæsar, in B.C. 47, and murdered after his escape to the Bosporus. (Suet., *Cæs.*, c. 35; Plut., *Cæs.*, c. 50; Appian, *Civ.*, ii. 91; Dio., xlii. 45-48.) Pharnaces left a son Darius, who was made king of Pontus by Antony, in B.C. 39 (Appian, *Civ.*, v. 75); but he was soon deposed, and Polemo appointed in his stead. (Dio., xlix. 25; Plut., *Anton.*, c. 38.) Polemo was killed in an expedition against the barbarians of Sindice, and was succeeded by his widow Pythodoris. (Strabo, xii., p. 556.)

Pontus was reduced to the form of a province by Nero (Suet., *Ner.*, c. 18), and was subsequently divided into three districts, called respectively Pontus Galaticus, Cappadocius, and Polemoniacus. In the time of Constantine another division of the province was made; the western part, which included Pontus Galaticus and Cappadocius, being called Helenopontus after Constantine's mother, and the eastern part preserving its name of Pontus Polemoniacus.

The history of the kings of Pontus is given in an appendix to the third volume of Clinton's 'Fasti Hellenici,' from which the preceding account has been chiefly taken.

After leaving Colchis, the first town of importance on the coast is Trapezus (*Trebizond*), a colony of Sinope. (Xen., *Anab.*, iv. 8, s. 22.) We learn from Arrian (*Periplus Pont. Euxin.*) that Trapezus was the most important town on the coast in the time of Hadrian. Tacitus also speaks of it (*Hist.*, iii. 47) as an antient and flourishing town. In the reign of Gallienus, Trapezus was taken and plundered by the Goths. (Zosimus, i., p. 32, 33.) In the thirteenth century it became the seat of a small empire under Alexius, a descendant of the Comneni (Gibbon's *Decline and Fall*, c. 61); and it retained its independence till the conquest of Constantinople by the Turks, to whom it was surrendered, A.D. 1461. Trebizond is still an important town. [TREBIZOND.]

Following the coast, the next town we come to west of Trapezus is Cerasus, afterwards called Pharnacia (*Kheresoun*), from Pharnaces, king of Pontus. Several antient writers say that Pharnacia and Cerasus were two different places; but since the antient Pharnacia is called at the present day Kheresoun, there cannot be much doubt that they are the same place, after the express testimony of Arrian (*Peripl.*) to that effect. Cerasus was a colony of Sinope (Xen., *Anab.*, v. 3, § 2), and was probably the place from which Lucullus first brought cherries into Europe. (Ammian., xxii. 8.).

West of Cerasus, on the coast, was Cotyora, an important town in the time of Xenophon, and also a colony of Sinope. (Xen., *Anab.*, v. 5, § 3-6.) In the time of Arrian it was a small village, which was owing to the inhabitants having been removed to the more modern town of Pharnacia. (Strabo, xii., p. 548.)

West of Cotyora and also on the coast near the river Thermodon was Themiscyra, celebrated in antiquity as the habitation of the Amazons. Themiscyra is mentioned by Herodotus (iv. 86). It was besieged by Lucullus in the war with Mithridates, and offered a formidable resistance to the Romans. (Appian, *Mithr.*, c. 78.) The last town of importance on the coast was Amisus (*Samsun*), which, according to Theopompus (*apud Strabon.*, xii., p. 547), was originally founded by the Milesians, but subsequently received an Athenian colony, and was called Piræus. It was greatly enlarged and beautified by Mithridates Eupator. (Strabo, xii., p. 547; Cic., *Pro lege Man.*, c. 8.) In the Mithridatic war it was taken by Lucullus, and subsequently came into the power of Pharnaces II. It was freed by Augustus from the tyranny of Straton, and in Strabo's time was in a flourishing condition. (Strabo, p. 547.) Pliny (vi. 2) calls it *liberum:* whence we may apparently conclude that in his time it had the Jus Italicum.

The most important towns in the interior were Amasia, Comana, Zela, and Neocæsarea. An account of Amasia, which was the birth-place of Strabo, is given under AMASIEH. Comana, surnamed Pontica, to distinguish it from a city of the same name in Cappadocia, was situated in the upper valley of the Iris. (Strabo, xii., p. 547.) It was a place of considerable mercantile importance, and was celebrated for its temple of the goddess Ma, who was supposed to answer to the Bellona of the Romans. There were 6000 slaves attached to the temple, the greater number of whom were courtezans. The office of high-priest was one of great honour and emolument. (Strabo, xii., p. 557-559.)

South-east of Comana was Zela (*Zeleh*), an antient temple, erected, according to Strabo (xii., p. 559), on the mound of Semiramis, and celebrated for a temple sacred to the goddess Anaitis. The priest of the temple was also sovereign of the town. Zela received an accession of territory from Pompey, and was made a city. (Strabo, xii., p. 560.)

Neocæsarea was situated to the east of Zela and Comana, on the Lycus. It is not mentioned by Strabo, but was a considerable place in the time of Pliny, and is spoken of by Gregory Thaumaturgus as the most important town in Pontus.

PONTYPOOL. [MONMOUTHSHIRE.]

PONZ, ANTONIO, a highly meritorious Spanish topographer and writer on the fine arts, was born in 1725, at Bexix, in the district of Segorbe in Valencia. His parents, who were persons of great respectability and considerable property, intended to bring him up for the church, and he was sent to pursue his studies accordingly, first at Segorbe, and afterwards at the university of Valencia, at both which places he gave proofs of more than ordinary ability and application. Yet, though he made sufficient progress in theology to be able to take the degree of Doctor, he had very little relish for it, while he had a decided inclination for the belles-lettres, for the study of foreign languages, and for the fine arts. His taste for the latter induced him to take lessons from his friend Antonio Richart, an artist of some repute at Valencia. His enthusiasm, if not his ability, determined him to renounce forthwith all idea of entering the church and to repair to Madrid, where he enrolled himself among the first pupils of the Academy of the Fine Arts. The course of instruction there given was far too methodical to suit his eager impatience, and he therefore determined to set out at once for Rome in the company of some Jesuits who were going thither. He proceeded to Italy in 1751, and, after visiting some other places, fixed himself at Rome, where he continued between nine and ten years, diligently examining all the chief antiquities and works of art, and also acquired considerable skill in the practice of painting, so as to be able not only to support himself, but to collect a number of the most valuable publications on art and antiquity.

From Rome he was attracted, in 1759, to Naples, by the discoveries made at Herculaneum and Pompeii, and the treasures of art he there met with so excited his enthusiasm, that he determined to visit Greece, Syria, and Egypt, and was deterred from that project only by the advice of Arostegui, the Spanish minister at Naples.

Ponz accordingly returned to Madrid; nor was it long before he obtained a commission that engaged him for a very considerable time. The king (Charles III.) was desirous of adorning the library of the Escurial with a series of portraits of eminent literary characters, and the choice fell upon Ponz, who was already spoken of as a person of very superior attainments. He passed between five and six years within the walls of the Escurial, where, when not occupied with his pencil, he found ample employment and recreation in the stores of literature and art there treasured up: he fancied himself, in short, in a second Rome. He there copied Raffaelle's celebrated Virgen del Pez, Guido's Virgen della Silla, and one or two other master-pieces.

Almost immediately after he had completed his labours at the Escurial, namely, the series of portraits placed in the upper library, he was appointed to visit the colleges, &c. of the Jesuits, then recently suppressed in Spain, for the purpose of taking an account of the paintings, &c. contained in them. It is to the circumstance of his being so employed that we are indebted for his 'Viage de España,' in 18 vols., a work of very great interest and value in itself, and not the less so because it affords a fund of information scarcely to be obtained from other sources. While it furnishes a most important contribution to the history of art, it is highly interesting on account of the original remarks and criticisms with which it is interspersed, and which attest the author's taste and learning. This publication and the different tours he made (chiefly through the southern provinces of the kingdom) occupied him from about 1771 to 1790, when his declining health prevented him from completing his plan. He died at Madrid, December 4, 1792.

Ponz was secretary to the Academy of the Fine Arts, to which office he was appointed in 1776, a corresponding member of the Royal Academy of History, and also mem ber of the Society of Antiquaries, London, and of several other learned bodies. Besides his principal work he published another in two volumes, entitled 'Viage fuera de España,' in which we meet with observations on some of the buildings in London.

PONZA, an island in the Mediterranean sea, off the coast of Naples, 20 miles south by west of Mount Circeo, and 35 miles south-west of Gaëta. It is about five miles long and from one to two wide, and in shape like a crescent, the concave side of which faces the mainland of Italy. On the same side is the harbour, which is a natural basin with a narrow entrance, surrounded by high ground, and perfectly safe in all weathers. The island is one continuous rock, mostly barren, but affording some pasture for cattle. Round the harbour are ranged some buildings, consisting of a castle, which is used as a state prison by the government of Naples, with a small garrison in it, and some other buildings, houses, and huts occupied by persons attached to the garrison and by fishermen. The Roman name of the island was Pontia. It was colonised by the Volsci from the opposite coast, and afterwards came into the possession of the Romans. About four miles west of Ponza is the smaller island of Palmarola, or Palmaria, and two miles north-east of Ponza is an uninhabited rock called Zannone. About 24 miles south-east of Ponza, and halfway between it and the island of Ischia, is the island of Vandotene, the antient Pandataria, whither Julia the daughter of Augustus was banished by her father in consequence of her dissolute conduct. Octavia the wife of Nero was also banished to Pandataria, and put to death there by order of her husband. Vandotene is about two miles long, and is inhabited by sailors and fishermen. East of Vandotene, and separated from it by a narrow channel, is the smaller island of Santo Stefano. The whole group of these islands is of volcanic formation.

(Fortis, 'Osservazioni Litografiche su l'Isole di Vandotene e Ponza,' in the 3rd vol. of the *Saggi Scientifici dell' Accademia di Padova*, 1794.)

POOLE, a corporate town on the coast of Dorsetshire, in 50° 43′ N. lat., and 1° 58′ W. long., 98 miles in a direct line south-west by west of St. Paul's, London, or about 116 miles from the General Post-office by the South-Western Railway to Southampton, and thence by Ringwood. The origin of Poole is unknown; it is supposed to have been an antient demesne of the crown granted to William Longespee, a natural son or descendant of Henry II. Longespee gave a charter to the burgesses of Poole, the date of which is not ascertained. This charter was confirmed by William Monteacute, earl of Salisbury, 45 Edward III., and by subsequent earls or by the crown. In 1365 Poole was made a magazine for the wars of Edward III. in France. After this period it decayed, but in the reign of Henry VI. it revived. It is likely that its early prosperity depended upon the vigour with which the war in France was carried on. In Leland's time it flourished, and in the reign of Elizabeth was resorted to by Spanish merchants. In the civil war it had a garrison of parliamentarians, who were troublesome neighbours to the royalist detachments in the county.

The town is upon a considerable inlet of the British Channel, which forms the harbour, and opens into the bay that lies between Hengistbury-head and Durlston-head. This inlet has a very narrow entrance which faces the east; it extends several miles inland, forming, when the tide is up, a large sheet of water, but presenting, when the tide is out, an assemblage of mud-banks divided by narrow channels. In the harbour are several islands; one of them, Brownsea island, having an area of several hundred acres, handsomely laid out, and some good buildings on it. The town occupies a peninsula on the north side of the harbour, and consists of several streets irregularly laid out, the principal of them running from north to south. The borough is co-extensive with the parish of St. James, and comprehends an area of 170 acres. The number of inhabited houses was, in 1831, 1315, besides 76 uninhabited and 11 building. The number of families was 1426, of persons 6459, besides 1119 mariners employed in registered vessels belonging to the port. The town had outgrown in some parts the corporate limits, and it may be calculated that its population in 1831 (exclusive of the mariners) was considerably above 7000, and has since then increased. A small suburb has grown up, separated from the town by an inlet of the harbour, over which there is a bridge. The houses in Poole are generally of respectable appearance, and some of them are of a superior class. The streets are paved: they are lighted and watched under a local Act. The guildhall was built in the middle of the last century, and there are a neat subscription and news room erected of late years, and a building for the public library. The church of St. James has been rebuilt of Purbeck stone; and there are an Episcopal chapel and several dissenting meeting-houses. There are a tolerably large gaol and house of correction for the borough, a custom-house, and an edifice of some antiquity, the king's hall or wool-house.

The trade which was formerly carried on with Newfoundland has much declined, but the coasting-trade has considerably increased. The quays have been much enlarged and improved, and the harbour is one of the safest and best on the Channel coast. The number of vessels from foreign parts which entered inwards in the years 1831, 1832, and 1833, averaged for each year about 100 with cargoes, and 20 in ballast; the average number which cleared outwards for foreign ports was above 110 with cargoes, and 45 in ballast; the number of coasters entered inward on the average of the same years was about 590 with cargoes, and nearly 350 in ballast; cleared outwards, nearly 1500 with cargoes, and 95 in ballast. The number of registered vessels belonging to the port in 1833 was 158. The clay found in the island of Purbeck is shipped here for the use of the potteries in Staffordshire or elsewhere; from 25,000 to 30,000 tons are shipped yearly. A considerable trade in corn is also carried on; and there are building-yards for vessels, and rope and twine walks. Sail-cloth is manufactured, and an active oyster and other fishery carried on.

The corporation of Poole, under the Municipal Reform Act, consists of 6 aldermen and 18 councillors. As the town is a county of itself, there is a sheriff annually elected by the burgesses. The borough had been much extended for parliamentary purposes, and the parliamentary limits have been adopted for municipal purposes until altered by parliament: it is divided into two wards. Quarter-sessions for the borough are held, and a weekly Court of Record, having unlimited jurisdiction in all cases, real, personal, or mixed. The sheriff holds a county court when necessary.

Poole returned two members to parliament in the 13, 36, and 42 Edward III.; it then discontinued sending them until 31 Henry VI., when the privilege was resumed, and has been continued ever since. The number of voters registered in the year 1835-36 was 498. The living of St. James at Poole is a perpetual curacy, of the clear yearly value of 307*l*., with a glebe-house; it is in the peculiar jurisdiction of Canford.

There were in the parish of St. James in 1833 twenty-nine infant or dame schools, with 455 children; an endowed free school with 22 boys; two Lancasterian schools, with 155 children; fourteen other day-schools, with 272 children; three boarding-schools, with 48 children; and five Sunday-schools, with 809 children: three of the Sunday-schools have lending libraries attached.

POOLE, MATTHEW, a learned non-conforming divine of the English Church, author of the well-known and useful book, 'Synopsis Criticorum Biblicorum.' He was born at York about the year 1624, and inherited from his family a good estate in that county. He was educated in Emmanuel College, Cambridge, but we have been unable to trace the circumstances of his history, till we find him, in 1662, in possession of the church of St. Michael le Querne in London, which he resigned, being unable to comply with the terms of ministerial conformity imposed by the Act of Uniformity passed in that year. Previously however he had exerted himself successfully in a scheme for the education of persons intended for the ministry, which was liberally patronised, of which, in 1658, he printed an account, in a book entitled 'A Model for the maintaining of Students of Choice Abilities in the University, and principally in order to the Ministry.'

Being ejected from his cure, and prohibited from the exercise of his ministry, he had leisure to devote himself to the completion of the great work which has made his name so extensively known. The design was nothing less than to bring into one view whatever had been written by critics of all ages and nations on the books of Holy Scripture. This, after ten years' labour, he completed, and the first two volumes appeared in 1669. These were followed by three other volumes, forming together five large folios, of which an extensive edition was printed. The work was perhaps as good as a work of the kind can be, and few will deny that it is a very valuable and useful abridgement; but synopses and abridgements are rather for the multitude than for scholars, who are rarely satisfied with the opinions of any author which are thus presented to them at second-hand and without that fulness of illustration which the author himself had given; yet, being written in the Latin language, it is manifest that the compiler contemplated a work adapted to the necessities and tastes of Biblical scholars. Its chief use may perhaps be said to be as a convenient body of exegetic criticism for Biblical students who are placed in situations which cut them off from convenient access to large libraries.

Besides this, there is an English work by the same author, 'Annotations on Scripture,' which was left by him unfinished, but completed by several of his non-conforming brethren. This work appeared in two volumes, folio, 1685.

He was also engaged in most of the controversies of his time: he attacked Biddle on the Socinian question; he published a defence of the non-conforming clergy in 1662; he wrote against the intrusion of laymen into the ministerial office; and he was the author of 'The Nullity of the Romish Faith,' 1666, and of other treatises in the controversy with the Papists. He retired to Holland to find the toleration which was denied him at home, and died at Amsterdam in 1679.

POOLE'S HOLE. [Derbyshire.]

POONAH, a city of Hindustan, in the presidency of Bombay and province of Aurungabad, is situated at the confluence of the rivers Moula and Mouta. It is about 80 miles south-east from Bombay, direct distance; in 18° 30′ N. lat. and 73° 52′ E. long.

Poonah stands on an extensive plain, or rather tableland, which is about 2000 feet above the level of the sea, and is bordered by hills which rise 1500 or 2000 feet above the plain itself. These hills are steep and rugged, and, previous to the conquest of the Mahrattas by the British forces in 1818, many of them were crowned by hill-fortresses, which are now however nearly all destroyed or fallen into decay. There are a few gardens in the suburbs of the city, but as both the gardens and the city lie in a hollow, the general appearance of the surrounding plain is naked and desolate.

Poonah was formerly the seat of the Mahratta sovereignty, and the residence of the Peishwa. It is not a handsome city, nor apparently of large size, though its extent must be considerable, since its population in 1819 was estimated by Mr. Elphinstone at 115,000, and Bishop Heber in 1825 was informed that it then amounted to about 100,000. The city is not walled, the houses are very irregularly built, and the streets are ill-paved and interspersed with peepul-trees. The bazars are mean: there are many pagodas, but none of them either large or handsome.

The palace of the Peishwa was large, and had a handsome quadrangle surrounded by cloisters of carved wooden pillars, but the external appearance was not striking. When Bishop Heber was there in 1825 the ground-floor of the principal building was used as a prison, and the floor immediately above as a dispensary; a large audience-chamber was fitted up as an infirmary for the natives, and a long gallery above this was converted into an hospital for the insane. A fire broke out in this palace in 1828, but we have not the means of ascertaining to what extent it was destroyed. Other small residences of the Peishwa were called 'Monday's Palace,' 'Tuesday's Palace,' &c. The most beautiful object is the temple of the goddess Parvati (the mountain-goddess), situated on an isolated and rather lofty hill immediately over the town, and at the bottom of which is a large tank surrounded by gardens.

A school for the instruction of the indigent was founded at Poonah in 1829.

The British have a military cantonment a little to the west of Poonah, which is laid out in wide streets and well arranged. It is much resorted to by visitors from Bombay.

The territory conquered from the Mahrattas in 1818 has, with the exceptions mentioned in the article Deccan, been divided into four collectorates, of which Poonah is one. Each collectorate is under the management of an officer with the title of collector, who is generally a military man, but who also exercises the functions of a judge of circuit and magistrate; but there is a chief commissioner over all, who resides at Poonah.

For an account of the Mahratta war and of the successive Peishwas who resided at Poonah, see the article Mahrattas.

The cave-temple of Carlee, to which reference is made in the article Aurungabad, is about a mile from Carlee, which is the last village on the great road across the Western Ghauts from Bombay to Poonah. The temple is hewn in the face of a rocky precipice, two-thirds up the side of a steep hill which is about 800 feet above the plain, and is approached by a narrow path winding up the side of the hill among trees and brushwood and fragments of rock. Besides the principal temple, there are many smaller apartments and galleries, in two stories, some of them beautifully ornamented. A mean and ruinous temple to Siva serves as a sort of gateway to the cave, and a similar small building stands on the right hand of its portico. The approach to the temple itself is under a noble arch filled up with a sort of portico screen in two stories of three intercolumniations below and five above. On the front of the portico, but a little to the left, is a high octagonal pillar, surmounted by three lions placed back to back. Within the portico, to the right and left, are three colossal sculptures of elephants, in alto-rilievo, with their heads, tusks, and trunks projecting boldly from the wall. On each of them is a driver, very well carved, and a palanquin, with two persons seated in it. The internal screen of the vestibule leading to the temple is covered with alti-rilievi of male and female figures, somewhat larger than life. The temple itself is about sixty feet long by thirty wide, surrounded on every side but that of the entrance with a colonnade of octagonal columns, the capitals of which consist of a large cap like a bell, finely carved, and surmounted by two elephants with their trunks entwined, and each carrying two male figures and one female. The roof is decorated with ribs of timber, which are not for support, but have a fine effect in the perspective of the interior. There is no image of Budda or any other idol in this temple.

(Heber's *Narrative of a Journey through the Upper Provinces of India in* 1824 *and* 1825; Mrs. Postans's *Western India in* 1838.)

POOR LAWS AND SETTLEMENT. A sketch of the early history of the English poor-law, down to the 43 Eliz., c. 2, will be found in the article Pauperism. Some account is also there given of the great evils which ensued from the subsequent maladministration of the law, and finally created the necessity for the Poor-Law Amendment Act (4 & 5 Wm. IV., c. 76). It will be convenient to state how the law stood previously to the passing of this Act, and then to notice some of its leading provisions.

Every indigent person, whether a native or a foreigner, being in any district of England or Wales, in which a fund is raised for the maintenance of the poor, has a right to be supplied with the necessaries of life out of that fund. This right depends on statute, and principally on the 43 Eliz., c. 2, which enacts that the churchwardens of every parish, and four, three, or two substantial householders there, to be nominated yearly under the hands and seals of two or more justices of the peace, shall be called overseers of the poor. [Overseers.] Under this statute overseers could be appointed for parishes only. This proved very insufficient, because many large and populous districts were not situate within any parish, and consequently no overseers whatever could be appointed for them; and also because many parishes themselves were of such magnitude that one set of overseers could not properly attend to all the poor. To supply this defect, the 13 & 14 Car. II., c. 12, authorised the appointment of overseers in any township that was either extra-parochial or was part of a parish so large as to require distinct sets of officers for the management of its poor. Townships are sometimes created also by local acts.

It is the duty of these overseers to raise and administer the fund for the relief of the poor of their district. This fund, which is called the poor-rate, they are directed by the statute of Eliz. in parishes, and by the statute of Car. II. in townships, to raise 'weekly or otherwise, by taxation of every inhabitant, parson, vicar, and other, and every occupier of lands, houses, tithes impropriate, propriations of tithes, coal-mines or saleable underwoods in the said parish, in such competent sum and sums of money as they shall think fit, &c. according to the ability of the parish.'

These provisions are still however, even since the 4 & 5 Wm. IV., c. 76, very inadequate. Overseers cannot be appointed, nor can a poor-rate be levied in any place that was not anciently either a parish or a township. Many districts which are very populous at the present day form no part of any parish or township; and the poor of such districts, if unable to remove themselves to a parochial division of the country, where they will be entitled to relief, may, as far as the law is concerned, perish from want.

The rate may be made according to the exigencies of the place, which, whether parish or township, may conveniently in either case be called a parish, for any period not less than a week nor exceeding a year. The rate, which is made in writing, gives the names of the persons rated, a description of the property for which they are rated, and the amount payable by them; it contains also a declaration, signed by the parish officers, that the rate is, to the best of their belief, correct, and that they have used their best endeavours to make it so. The rate so made and signed must be taken to two justices for their assent, which is called the allowance of the rate, and public notice of such allowance must be given on the Sunday following, or the rate will be entirely void.

As the statute expressly mentions both inhabitants and occupiers, inhabitants were held liable to be rated in proportion to their ability within the parish, although they had no property there which was capable of occupation, and occupiers of property therein were held liable although they resided elsewhere. Accordingly both real corporeal property and personal property within the parish may be assessed, as constituting 'the ability of the parish;' real corporeal property, as land or houses, may be assessed, wheresoever the occupier resides, and personal property, if the owner is resident within the parish. Incorporeal real property, since it is not the subject of occupation, seems not to be rateable unless incidentally, when, as in the case of the tolls of a canal, it is, as it were, annexed to and enhances the value of corporeal real property, which is the subject of occupation. As it is the occupier and not the owner of real corporeal property who is rated for it, it will be obvious that the term 'real property' is not used in the poor-laws according to its strict legal sense, and that the occupier of a house is rated for it, although he has a mere chattel interest in it. The term 'personal property' is also used in a restricted sense; it denotes stock in trade, and such things as are not at all of the nature of realty, and excludes chattels real. The assessment is laid in respect of the revenue or annual profit of the property rated, whether real or personal. Such property therefore as is incapable of yielding profit is not rateable. The assessment upon land and houses, &c. is calculated upon an estimate of their net annual value, which is defined to be the rent at which they would let from year to year, free of all tenant's rates and taxes, and tithe commutation rent-charge, if any, and deducting the probable average of annual costs of repairs, insurance, and any other expenses which may be necessary to maintain the premises in a state to command such rent. Personal property was not rated unless it had, as it were, a local existence; and therefore neither stock in the funds nor money was rateable. Furniture also was exempted, because it yielded no profit. In practice the only kind of personal property ever rated, and that in very few places, was stock in trade and ships. The rating of this species of property was attended with many disadvantages. The rate was to be made on the profit, which was defined to be not the whole profit, but the excess after payment of debts. Thus it was nearly impossible to ascertain the rateable amount of such property, and the proprietor might always evade the tax by residing out of the parish. So long however as personal property was rateable by law, the omission of it in the rate was a ground of appeal, because all persons liable are to be rated equally according to their ability. The inconvenience of this state of things induced the legislature during the present session of parliament (1840) to enact (by 3 and 4 Vict., 4, c. 89) that no inhabitant should be rated for his stock in trade or other property. The word 'inhabitant' may now be considered as struck out of the statute of Elizabeth; nobody will have to contribute henceforward to the poor-rate except in his character of occupier. Personal property therefore is no longer rateable.

It is unnecessary to make any detailed remarks on tithes and other property which, by the statute of Elizabeth, are expressly made chargeable.

If a parish is unable to furnish a sufficient sum for the maintenance of its poor, any other parish in the same hundred, with the sanction of two justices, or in any other part of the county, with the sanction of the justices at quarter-sessions, may be called upon to assist the less solvent parish. This is called rating parishes in aid.

The overseers are to collect the rate from the persons rated. If a person rated do not pay when called upon, the overseers may obtain a summons from two justices, requiring him to show cause why a warrant should not issue to levy the rate by distress and sale of his goods; and, if no sufficient cause is shown, the payment is enforced accordingly. The party so summoned may show for cause that the rate itself is void, or that he is not liable; he may also, with the consent of the overseers, be excused, if it appear that he is unable to pay through poverty. He may also appeal against the rate, and notice of appeal deprives the magistrates of their jurisdiction to distrain until the appeal is decided, unless the objection is solely on the ground of overcharge, in which case the warrant may issue for such a sum as the property was rated at in the last valid rate. The appeal againt the rate on the ground of inequality, unfairness, or incorrectness in the valuation of the property rated may be to justices at petty-sessions, from whose decision a second appeal lies to the general quarter-sessions. The appeal, on the above grounds, may also be taken to the quarter-sessions in the first instance. If the objection be to the principle of the rate itself, or it is intended to dispute the liability of the property to be rated, the appeal lies to the quarter-sessions only. In all these cases of appeal, notice of appeal and of the precise objections to the rate must be given to the parish-officers, and also to any rated inhabitants that may be interested in opposing the appellant, as, for instance, where his ground of complaint is that they have been under-rated.

The overseers, who in some parishes act under the direction of a select vestry, and are assisted by assistant overseers, are to apply the poor-rate to the relief of the poor of their parish. The poor of the parish are, in one sense, all those who happen to be in the parish at the time of their being in distress; for the parish in which they happen to be is bound to afford such paupers immediate, or, as it is called, casual relief. But if the same parish were bound also to afford continued relief to, or permanently to maintain, all the destitute who should come within it, the burden of supporting the poor might press very unequally upon different parishes. Paupers would then, influenced by their own fancy, or instigated to exonerate some other parish, have the power of fastening themselves for ever on any particular parish, or of roaming at pleasure from one parish to another in unrestricted vagrancy. The 13 & 14 Car. II., c. 12, was passed to obviate these evils, and is the foundation of the present law which determines the parish that a pauper belongs, and gives the power of removing him to it. This law is called the law of settlement. The statute enables two justices, upon complaint made by the churchwardens or overseers of the poor of any parish, to any justice of the peace, within forty days after a person coming to settle there, in any tenement under the yearly value of 10*l*., by their warrant to remove such person to the parish where he was 'last legally settled, either as a native, householder, sojourner, apprentice, or servant, for the space of forty days at the least.' Later statutes have greatly modified the heads of settlement here enumerated, and have added others; they have also made a pauper irremovable, until he has become chargeable to the foreign parish by receiving relief from it, either in person or through the hands of his wife or children.

The following are the settlements that subsisted at the passing of the Poor-Law Amendment Act:—settlement by birth, parentage, marriage, hiring and service, apprenticeship, renting a tenement, estate, office, payment of rates. Settlements may be divided into two general classes; being, first, natural or derivative settlements, as by birth, parentage, or marriage, to the perfection of which residence in the parish is unnecessary; secondly, acquired settlements, including all the remaining settlements above mentioned, and to these residence for forty days in the parish is necessary. The following were the modes of acquiring the various settlements which have been enumerated:—1, settlement by birth.—In order that children may not be separated from their parents, the settlement of the father during his life, and the settlement of the mother after his death, is the settlement of the children. But legitimate children who have no known settlement are settled in the place of their birth; so also are illegitimate children, for they can derive neither settlement nor any thing else from their parents. Children however, during the age of nurture, which continues till they are seven years of age, must not be separated from their parents, and are therefore to be supported in the parish where their parents happen to be, at the expense of the parish of their birth settlement. 2. Settlement by parentage.—The settlement of the father, or, if he have none, the maiden settlement of the mother, is communicated to legitimate unemancipated children. After the father's death their settlement shifts with that of the widow, until she marry again, in which case the settlement of her new husband is not communicated to them. A child is said to be unemancipated so long as he forms part of the parent's family. A child is emancipated when he gains a settlement of his own, or, being of the age of twenty-one, lives apart from and independently of the parent, or contracts some relation inconsistent with his continuing a subordinate member of the parent's family, as by marrying or enlisting as a soldier. Any settlement of the parent acquired after the child's emancipation is not communicated to him. 3. Settlement by marriage.—To prevent the separation of husband and wife, the settlement of the husband is communicated to the wife; she can acquire no settlement during marriage; and, if he have no settlement, she cannot be separated from him by removal to her maiden settlement. 4. Settlement by hiring and service is acquired by a person unmarried, and without unemancipated children, hiring himself for a year into service, abiding for a year in the same service, and residing for forty days in any parish within the year, and with a view to the service. A general hiring, that is, a hiring where nothing is said as to the duration of the contract, is considered a hiring for a year. The service for the year need not be wholly under the hiring for a year, it is sufficient if part of the service be under such hiring; the residue may be either under another hiring, or under no hiring at all. The settlement is gained in the parish where the servant last *completes* the residence of forty days—the forty days need not be consecutive days; if the servant reside thirty-nine days in parish A, then forty days in parish B, and finally another day in A, A, where he last completed a residence of forty days, will be the place of his settlement. All the forty days must be within the compass of a single year, but it is sufficient if the residence for any part of the forty days be under the yearly hiring. 5. Settlement by apprenticeship is gained in the parish where a person bound by deed as an apprentice last completes a residence of forty days in his character of apprentice. No service is required, but the apprentice during the necessary period of residence must be under his master's control. 6. Settlement by renting a tenement is acquired by hiring and actually occupying a tenement at the rent of at least 10*l.* a year, payment of rent to that amount, and residence for forty days in the parish where the tenement is. By actual occupation is meant that no part of the tenement must be underlet. 7. Settlement by estate is gained by the possession of any freehold, copyhold, or leasehold property, and residence for forty days in the parish where the estate lies. If the estate come to a party in any way except by purchase, the value of the estate is immaterial; but a purchased estate confers no settlement if the price given was under 30*l.* But a person residing on his estate, whatever may be its value, is by Magna Charta irremoveable from it while so residing, although he may have gained no settlement in respect of it. 8. Settlement by office is gained by executing any public office in a parish, such as the office of constable, sexton, &c. for a year, and residing there forty days. The office need not be of a parochial nature, but it must be at least an annual office. 9. Settlement by payment of rates.—In order to acquire this settlement a person must have been rated to and have paid the public taxes of a parish, in respect of a tenement hired at a rent of 10*l.* a year, and have paid that amount of rent, and resided forty days in the parish of the tenement. This head of settlement therefore includes all the requisites of settlement by renting a tenement, except the requisite of actual occupation.

All persons whatsoever, whether natural born subjects of England and Wales, Scotchmen, Irishmen, or foreigners, may gain a settlement in this country. A chargeable pauper is to be removed to the place where he last acquired a settlement. It is often very difficult to find out the place of such last settlement; this is so more especially in cases of settlement by hiring and service and apprenticeship, where the residence, being unconnected with anything of a fixed nature, as a tenement or office in any particular parish, may be continually shifting, the settlement consequently shifting with it, until the last day of the service or apprenticeship. Paupers who have no settlement must be maintained by the parish in which they happen to be, as casual poor, unless they were born in Scotland or Ireland, or in the islands of Man, Jersey, or Guernsey, in which case they are to be taken under a pass-warrant of two justices to their own country. When a pauper has become chargeable, and it is sought to remove him, he is taken before two justices, who inquire as to his place of settlement, and, if satisfied, upon his examination and such other evidence as may be laid before them, make an order for his removal thither. The parish to which he is removed may dispute its liability by appeal to the quarter-sessions, when the order of removal will be quashed, unless it appear that the pauper is settled in the appellant parish.

The Poor-Law Amendment Act (4 and 5 Wm. IV., c. 76) has made no change in the law respecting the rateability of property or the mode of collecting the rate. The act does not apply itself to the rate until collected; it then takes up the rate for the purpose of securing a better distribution of it. To this end the administration of relief to the poor throughout England and Wales is subject to the control of three commissioners. Their powers, and the new agency established for the administration of relief under their direction, have been already described. [PAUPERISM.] In parishes or unions where there are guardians or a select vestry, relief is to be given solely by such guardians or vestry, or by their order, unless in cases of urgent distress. In these cases an overseer is bound to give temporary relief in articles of absolute necessity, but not in money, and, if he refuse, he may be required to do so by a magistrate's order, disobedience to which is visited by a penalty of 5*l.* In parishes which have no guardians or select vestry, the management and relief of the poor is still left to overseers, subject to the control of the commissioners. But, with the exceptions above stated, the task of relieving the poor is wholly withdrawn from overseers, these officers, from ignorance or corrupt motives, having been generally found incompetent to the discharge of so important a duty. They are still however entrusted with the making and collection of the poor-rate, which they are to pay over to those who have the distribution of it. The general discretionary power which magistrates formerly exercised in ordering relief is also withdrawn. But a single magistrate may still order medical relief, when called for by sudden and dangerous illness; and two magistrates may order relief to adult persons, who from age or infirmity are unable to work, without requiring them to reside in the workhouse. Relief to able-bodied persons cannot be given out of the workhouse, unless with the sanction of the commissioners. In substance, the wants of the poor are as amply supplied as before the Act, but the manner of administering relief is so regulated, by subjecting the applicants for it to the discipline of a workhouse and to other restraints, that the condition of a pauper, living upon the parish fund, is depressed, in point of comfort, below that of the labourer. Thus a ready test is applied to distinguish real and pretended destitution, and a powerful incentive to work is held out to all who can find employment.

The means also of obtaining employment are increased by enlarging the market for the poor man's labour. This is the result of a relaxation in the law of settlement, and particularly of settlement by hiring and service. The old law had been found to obstruct the free circulation of labour by confining the poor to their own parishes. The labourer himself, from attachment to old scenes and associates, was often unwilling to engage himself for a year in a strange parish, lest, by acquiring a settlement there, he should incur, at some future time, a permanent separation from home: the farmer, on the other hand, had an equally strong objection to hire a strange labourer on such terms as to burden his parish with a new settler.

By the Poor-Law Amendment Act a settlement by hiring and service cannot be acquired for the future; but the Act does not interfere materially with settlements previously acquired. Settlements by office and by apprenticeship in the sea service or to a fisherman can no longer be acquired. Settlement by renting a tenement is clogged with the additional qualification that the occupier must have been assessed to the poor-rate, and paid the same for one year. Settlement by estate, like any other settlement, when once gained, used to endure till it was superseded by some new settlement; but now it is converted to a temporary settlement, and to be retained so long only as the proprietor shall live within ten miles of the estate. Settlements by marriage and by payment of rates are untouched. Settlement by parentage and settlement by birth are both affected to this extent, that illegitimate children born after the passing of the Act are to follow the settlement of their mother, until the age of sixteen, or until they acquire a settlement in their own right; instead of taking, as formerly, the settlement of the place of their birth. The effect of this change in the law is that an unmarried woman, whose pregnancy in itself made her chargeable, is no longer hunted from the parish in which she happens to be, in order that the parish may not, by the birth of the child therein, be permanently charged with its maintenance. The old law of settlement was full of legal difficulties and refinements, and the effect of the change in the law has been to relieve parishes from a frightful mass of litigation.

A great change also has been introduced in the general law of bastardy. Formerly the putative father was liable for the support of a bastard, on the unsupported oath of the mother that he was the father of it. Before the birth of the child, he might be called upon to give security to provide for the child, and, if unable to give such security, might be committed to prison; and, after its birth, an order of filiation might be made upon him by two justices out of sessions. By the new Act neither the mother nor the putative father of a bastard can be punished, as was formerly the case. Female incontinence is checked by making the mother liable to maintain her child in the first instance. The putative father is resorted to only in the event of her inability, and no order of maintenance can be made upon him, except at quarter-sessions, and the evidence of the mother must be corroborated in some material particular. By a still more recent Act the order is to be made at petty-sessions, unless the putative father desire that the case may be heard at the quarter-sessions, and give security to abide by the judgment of that court.

Any person who marries a woman having children, whether legitimate or illegitimate, is made liable to maintain them until they attain the age of sixteen, or until the death of the mother.

The compulsory provision for the poor, which has been introduced into Ireland, by 1 and 2 Vict., c. 56, has been already noticed. [PAUPERISM.]

A compulsory provision for the poor has been in force for about two centuries in Scotland. The Scotch law resembles in many respects the English law, but has been more wisely administered. In Scotland however the able-bodied have no legal right to relief. (Monypenny on the 'Scotch Poor-Law;' *Edin. Rev.*, vol. lix., p. 425.)

(Bl.'s *Comm.*, 359; Nolan's *Poor Laws:* Burn's *Justice*, 'Poor;' and Gambier *On the Law of Settlement.*)

POPAYAN. [GRANADA, NEW.]

POPE, ALEXANDER, was born in London, May 22, 1688. His parents were Roman Catholics, and his father, who, according to Pope's own account, was of a noble family, kept a linen-draper's shop in the Strand. In his early years, his father retired to Binfield in Windsor Forest, and here Pope formed his first plans of study, and, while yet a child, determined to be a poet. The 'Pastorals' were composed when he was sixteen, but not published till he was twenty-one (1709), in Tonson's 'Miscellany.' He next produced the 'Essay on Criticism,' and not long after appeared the 'Rape of the Lock,' and 'The Temple of Fame,' a partial imitation of Chaucer. In 1713 he published 'Windsor Forest,' and soon after this date the proposals for a subscription to a version of the 'Iliad.'[*] The whole work was completed between his twenty-fifth and thirtieth year. The fame which it procured for Pope, joined, as is probable, to his own ill-temper, lost him the friendship of Addison, but probably raised him to the place which Addison had filled as leader of the literature of the day. In the translation of the 'Odyssey,' Pope was helped by Broome and Fenton. Pope translated twelve books, Broome eight, and Fenton four.

In 1728 he published 'The Dunciad,' and in 1733 the Essay on Man,' which however was not avowed till the next year, when he wrote his 'Characters of Men, or Moral Essays. These were preceded and followed by 'Imitations of Horace,' and in 1742 the list of his poems concludes with an additional book of 'The Dunciad,' in which Cibber takes the place of Theobald, the original hero. About this time his health declined, and on the 30th May, 1744, he died of asthma and decay of nature.

To enumerate the friends of Pope would be to give a list of the great men of the time. One of his failings was to desire the acquaintance of men of fashion, and his literary supremacy gave him that of men of learning, so that he commanded a very large circle. Among them were Addison, with whom he quarrelled; Swift, to whom he addressed the 'Dunciad;' Atterbury, on whose trial he appeared as a witness for the defence; Bolingbroke, to whom he is said to have owed the maxims of the 'Essay on Man;' and Voltaire.

Pope was short and deformed. It is surprising that he should have lived so long as he did, having both physical infirmity and hard study to contend against, with the addition of a violent temper, over which he had so little control, that he could not avoid showing anger by the very contortions of his countenance. Perhaps there is nothing in the history of literature more remarkable than the popularity acquired by Pope. To attain, in the estimation of a great nation, to the first rank among her poets, themselves the greatest which any nation has to boast, is no mean distinction; but that it should have been acquired on the strength of such poems as Pope has left, is not less wonderful. An enumeration of his principal works will show that, with one or two trivial exceptions, his very subjects were borrowed from some other writer. His 'Pastorals' are a mixture of Virgil and Theocritus, and have little to recommend them, except what is common to all the verses of his school, a beautiful flow of words and an epigrammatic turn of expression. This by convention has received the name of poetry, but if by poetry we mean anything more than ingenious thoughts put into ornamented language, if poetry is indeed to be what the Greeks understood by it, a creation, we shall find little of it here. Even the 'Messiah,' beautiful as it undoubtedly is, has little claim to the title of a poem. Indeed, it professes nothing more than to be an imitation.

The 'Essay on Criticism' is worth notice, as, combined with Pope's preface to his works, it shows very clearly what influence was most predominant in forming the prevailing style of versification in his time. That any man possessed of any measure of poetic spirit should be so tremblingly alive to what others said of him, as in his second work to employ himself in canvassing the merits of critics and the rules of criticism, is certainly not what we might expect. He who has given birth to a high production of the imagination cannot help feeling that its merit rests upon other grounds than the decisions of any man or party of men, and remains satisfied in the pleasure which the exercise of any noble faculty always gives, without troubling himself to inquire what 'the critics' have said upon it, or what is the general verdict of his readers. At the time when Pope wrote however, authorship was reduced to a kind of system. The end in view was to please the readers: the readers themselves were almost entirely of one and that a limited class; the class who read were members of the fashionable world, and frequented coffee-houses, the clubs of those days. At these coffee-houses some one presided; and hence by getting the ear of this president, or, what was better, by taking his place, an author became in great measure the judge of his own work. Dryden's literary supremacy could never recur among us, for it requires a confined class, and a very peculiar state of society to secure so general a reputation. However Dryden obtained it, and, by doing so, set the fashion. The booksellers favoured it, for nothing could be so convenient to them as to have under their command the rulers of literature; and the effect of all this was to make Pope an imitator of Dryden, and all the other poets of the day imitators of Pope, as the person whose style was the most approved by those whom Addison and Pope and their contemporaries call 'the town,' the only literary tribunal then in being. If we were to give a reason for the predominant influence possessed by 'the town' in Pope's days, an influence which continued till the French revolution, we should ascribe it to that revulsion in favour of the court which succeeded the Restoration, and which the unpopularity of James was unable to destroy, joined to the influence which French manners and modes of thought had acquired to the prejudice of the old English spirit of the early part of the seventeenth century.[*]

---

[*] A full account of the bargain with Lintot, the price of the work, &c., are given in Johnson's 'Life of Pope.'

[*] A curious instance of Pope's omnipotent authority is given in the notice of SURREY.

The preface which Pope prefixed to his works is quite as remarkable as the 'Essay on Criticism,' in assuming, as it does from beginning to end, that the proper object of a writer is to please. It is curious also, as a memorial of that fashion which poets then followed in dedicating their work to some great man, and in rehearsing patron's names and titles; all which follies Pope ridicules, though at the same time he is governed by the spirit which dictated them, and boasts that he had been 'encouraged by the great, commended by the eminent, and favoured by the public in general.'

Translations and imitations are an important part of Pope's works. Of these the most remarkable are the versions of the 'Iliad' and 'Odyssey,' perhaps the most generally read of all his writings. It is of course pretty well known at present that Pope's claims to the name of a translator are very small. He has contrived to throw an air of Virgilian elegance and courtliness over the simple verses which formed his subject, but it would be hard to show a more thorough disguise than that which the 'Iliad' puts on in Pope's English, and this in spite of his very frequent use of Chapman's version. All scholars will admit that Pope has latinized the 'Iliad,' a very prevalent fault in his day, when Latin held a place so much more important than Greek in the estimation of literary men. For his imitations of some parts of Chaucer this apology may be made, that they were written very early. A comparison of their style with that of Mr. Wordsworth's 'Prioress's Tale,' shows what might have been done, but between Pope and Chaucer there is about the same difference as between a conservatory and a bank of wild flowers in a forest.

In Pope's days it was the fashion to be a philosopher, whence it was necessary for Pope to compose a philosophic poem. It might perhaps have been well to weigh a little the consequences which theories like those of 'The Essay on Man' would have in practice, before making them the foundation of a system; but this was no part of Pope's scheme, and out of his materials, supplied, as is thought, by Bolingbroke,* he has written a poem, many lines of which are immortal, while the sentiments are mostly very mischievous, and the facts not seldom fictions.

In his imitations of Horace, Pope has been most happy: indeed, where the parties have so much in common, it was to be expected that the imitator would be successful. Dazzling point and harmonious verse are combined in these delightful compositions, which are worthy of all praise. Indeed these are the characteristics which have given Pope his popularity. But they do not constitute poetry, nor is the man who possesses them only, therefore to be considered a poet. To Pope they were doubtless temptations too strong to be resisted. He who could write so well in the fashion was not likely to sacrifice fame by writing better against the fashion.

One important poem remains unnoticed, 'The Dunciad;' in which we may trace Pope's chief excellencies, and the subject being one to which his manner is peculiarly adapted, the poem on the whole appears to be the most perfect of his compositions. In 'The Dunciad' too we may discover Pope's true merit—that of having been the first to wage successful war against that crowd of verbal critics and worthless rhymsters which overran literature. The manner in which he holds up to ridicule the poets, booksellers, and critics of the time is admirable, and the number of lines of 'The Dunciad' which are in constant use as quotations, are the best proof how stinging the satire must be. Theobald was the first hero of 'The Dunciad,' and owed his exaltation to having attacked with success the mistakes in Pope's edition of Shakspere. He was succeeded in a subsequent issue by Colley Cibber, who stands as such in the present poem.

An excellent parallel has been drawn by Dr. Johnson between Dryden and Pope. It is perhaps too favourable to the latter, but shows a clear insight into the merits and faults of both. We cannot speak so favourably of the defence of Pope's 'Iliad.' To imply, as Dr. Johnson does, that the advance of civilization required the addition of Ovidian graces in a translation, shows an ignorance of the true principles of the art. Indeed it is hard to point out a good work of the kind from the time of Dryden downwards, with the exception of Dryden's Virgil, until we come to Coleridge, Cary, and the other successful translators of our own day, Dr. Johnson's own translations of Juvenal and Pope's of Horace only excepted. It thus appears that the Latin was the only tongue which met with successful translators from Dryden to Coleridge; Dryden's own style, and the character of the times, having joined to give all verse a Virgilian or Ovidian character.*

It only remains to state that as a prose writer Pope is considered to have attained considerable merit. His style is elegant and cautious, much more correct and much less attractive than Dryden's. Pope's Works, with his last corrections, and notes and a commentary by Warburton, were published in 1751 and 1760, London, 9 vols. 8vo. There is a modern edition by Roscoe, London, 10 vols. 8vo.

(Johnson's *Lives of the Poets*; Wordsworth's *Supplement to the Preface to his Poems.*)

POPE (*Papa*, in Latin) is the title assumed by the bishop of Rome as head of the Roman Catholic Church. The word papa, or papas, meaning 'father,' is used by the Greeks to denote a presbyter. In the early ages of the church it was given to the bishops in general. (Ducange, *Glossarium;* Moreri, *Dictionnaire Historique.*) Gregory VII., in a council held at Rome, A.D. 1076, decreed that the title Papa should be given only to the bishop of Rome, as a mark of superior respect.

There are three offices or dignities united in the person of the Roman pontiff. He is—1, the primate or head of the Roman Catholic world; 2, he is bishop of Rome and metropolitan of its province; 3, he is the temporal sovereign of the Papal State. His authority and the manner of his administration in the last-mentioned capacity are described under PAPAL STATE.

Considered as pontiff and primate of the Roman Catholic church, the pope has a very extensive spiritual authority over the members, both clerical and lay, of that communion. The limits of this authority are however variously defined even by Roman Catholic theologians. We cannot do better than quote on this subject the definition given in a work of considerable repute and written with great discrimination, which is entitled 'Bibliothèque Sacrée, ou Dictionnaire Universel, Historique, Dogmatique, Canonique, Géographique, et Chronologique des Sciences Ecclésiastiques, par les Révérends Pères Richard et Giraud, Dominicains; réimprimé avec additions et corrections par une Société d'Ecclesiastiques,' 20 vols. 8vo., Paris, 1822. Under the head 'Pape,' section iii., *De la Puissance et Authorité du Pape*, we read as follows:—1. 'All Catholics acknowledge that the pope holds by divine right a primacy of honour, of precedence, and of authority and canonical jurisdiction in the whole church, because he is the successor of St. Peter, to whom Jesus Christ granted those privileges. (*Matthew*, x. 2, and xvi. 17-19.) But is the pope infallible in his decisions concerning law or discipline? Is he above the general council? Has he any power, direct or indirect, over sovereigns and kingdoms? Divines are very much divided in opinion upon these questions.'

2. 'We may consider the pope either as a private and individual doctor of the law, or as the sovereign pontiff speaking "ex cathedrâ" in his quality of head of the universal church, to which church he proposes something to be believed as an article of divine faith, under pain of heresy, and this he does after having prayed, having consulted the sacred college of cardinals, and employed the other customary means in order to ascertain the truth. Now the French theologians in general, agreeably to the fourth proposition of the Gallican church, maintain, that even in this case, when he speaks "ex cathedrâ," the pope is not infallible, and that his decisions become infallible only after they have been accepted by the church, either in council assembled or dispersed in its various congregations throughout the world The Italian divines, on the contrary, commonly assert that the pope is infallible when he speaks "ex cathedrâ," independently of the consent of the church. They ground their assertion on the passage in St. Matthew, "Tu es Petrus," &c. "How," say they, "can the church be infallible, if the foundation upon which it is built be not infallible? Does the church rest upon Peter, or Peter upon the church?" To this their opponents reply—1, that the rock upon which the church is built means faith, and not the person of Peter; 2, that the promise of infallibility was made to the whole church, and not to Peter individually; 3, that all the passages which are quoted from the Scriptures or the fathers in favour of the infallibility of the pope apply not to the individual who is seated on the chair of St. Peter, but to the

---

* See the Poem itself, iv. 333.

* See the preface to Hoole's 'Tasso' for the contempt in which old translations were held.

chair itself, to the see of Rome, the Roman church, the whole succession of the Roman pontiffs, the universal church in short.' The writer of the 'Bibliothèque Sacrée' winds up these conflicting statements by saying, 'This question is not one of faith.' To this remark however some will object, that the question is considered as one of faith at Rome, for as the Roman (or, as the French call them, the ultramontane) canonists assert the infallibility of the pope by divine right, it follows that they consider the belief in that infallibility, and in all the decisions emanating from it, as matters of faith; and as long as this controversy remains unsettled, a door is always open to schism, as it happened in the council of Basle, and the alleged unity of the Roman Catholic church is only nominal and precarious.

3. 'The same theologians who assert the infallibility of the pope, assert also his superiority above the general councils, and that he has the right of dissolving them, transferring them to a different place, of approving or condemning, reforming or abrogating their decisions. Those divines, on the contrary, who maintain that the pope is not infallible, maintain also that he is subject to the general councils both as to faith and discipline. This is the opinion of the French clergy, embodied in the second of the four propositions of the Gallican church, promulgated in 1682, which 'approves the decision of the council of Constance, declaring the councils general to be superior to the pope in spiritual matters.' The assertors of this proposition say that 'the pope is the head of the faithful nearly in the same manner as the general of a monastic order is the head of all the members of that order, to whom however he is subject when they are assembled in a general chapter.' It may be observed here, that besides the council of Constance, which decided this question of the superiority of the general councils over the pope, there is the council of Basle, which asserted the same principle, and that the council of Basle is reckoned by the French theologians among the legitimate councils of the church, but is not so reckoned by the canonists of Rome. [PRAGMATIC SANCTION.]

4. 'There are some writers who pretend that the pope has by divine right a direct power, both spiritual and temporal, over the whole world. Others maintain that he has at least an indirect power in temporal matters, inasmuch as he can dispose of kingdoms and crowns, and transfer them from one prince to another whenever that is required for the welfare of souls. Lastly, other divines are of opinion that neither the pope nor the church has any power, direct or indirect, in the temporal matters of kingdoms and states, that they cannot in any case depose kings, nor release their subjects from their oath of allegiance. In support of their argument, these divines show that Jesus Christ made open profession of poverty, that he solemnly declared that his kingdom was not of this world, and they allege other passages as equally decisive; and they say that the Saviour bequeathed to the church a purely spiritual authority, to be exercised in preaching, baptising, instructing, and loosening or binding sinners. The early fathers have said that the church has only the spiritual sword to keep its children within the path of duty. The most celebrated universities of Germany, France, and Spain have confirmed this opinion, which is that of the Gallican church and of Bossuet himself. The contrary opinion, namely, that the popes have a temporal jurisdiction over kings and principalities, is not of older date than the time of Gregory VII.'

Such are the statements of orthodox Roman Catholics in a work which condemns all heretics and Jansenism, for the Jansenists assert that the pope has no authority over the bishops, but only a superiority of rank; that all the bishops are vicars of Christ, and that the pope is the first among them, and that his jurisdiction is not to confer episcopacy, but only to watch over the conduct of the other bishops, &c. These opinions of the Jansenists are found, among other works, in the 'Acts of the Synod of Pistoia held by De Ricci' (*Atti e Decreti del Concilio Diocesano di Pistoia dell' anno* 1786), which were condemned by Pope Pius VI. As for the Protestant and Reformed churches, they do not acknowledge any authority or jurisdiction in the pope, except over his own diocese as bishop Rome, or at most over the other dioceses of the province of Rome as metropolitan. The Greek, Armenian, Jacobite, and Nestorian churches likewise disclaim his authority. Several Roman Catholic writers have endeavoured to trace the growth of the supremacy of the Roman see over the churches of the West, which supremacy they assert was once limited to the provinces which constituted, under the Christian emperors, successors of Constantine, the vicariate of Rome, namely, Etruria, the March of Ancona, Valeria, Apulia, Calabria, Lucania, the Abruzzi, Sicily, Sardinia, and Corsica. These provinces were under the lay jurisdiction of an imperial vicar. The rest of Italy, with Rhætia, constituted the vicariate of Italy, of which Milan was the capital. Both vicariates were subject to the prefect of Italy, who had also under his authority the provinces of Africa and Illyria. The provinces which formed part of the vicariate of Rome were called 'suburbicariæ,' and their diocesans acknowledged the bishop of Rome as their metropolitan. Such is the opinion of Father Sirmond, and of Du Pin, in his 'De antiquâ Ecclesiæ Disciplinâ,' and of Giannone, in his 'Storia civile del Regno di Napoli.' They contend that until the reign of Valentinian III. the metropolitan authority of the bishop of Rome did not extend beyond the suburbicarian provinces. Allatius, Baronius, Maimbourg, and others, on the contrary, contend that the bishop of Rome was by right the metropolitan of the whole West, if not of the whole Roman empire. Gregory I. (the Great) however disclaimed the title of Œcumenic or universal bishop, and in token of humility assumed that of 'Servus Servorum Domini,' the 'Servant of the Servants of the Lord,' which his successors have continued to place at the head of their briefs and decretals.

In his quality of bishop of Rome, the pope delegates his authority as ordinary to a prelate called Vice-Gerente, who is generally a bishop in partibus. In his quality of metropolitan of the province of Rome, he has under him the bishops called Suburbicarii of Ostia and Velletri, of Porto and Santa Rufina, of Sabina, of Frascati, of Albano, and of Palestrina. As primate of the Roman Catholic church, he has under him the following sees:—In the Papal State, 8 archbishops and 59 bishops; in Tuscany, 3 archbishops and 17 bishops; in the kingdom of the Two Sicilies, 23 archbishops and 73 bishops; in the Sardinian monarchy, 7 archbishops and 34 bishops; in the duchy of Parma, 4 bishops; in the duchy of Modena, 4 bishops; in the duchy of Lucca, 1 archbishop; in the Austrian empire, 13 archbishops and 71 bishops; in the rest of Germany, 5 archbishops and 20 bishops; in Switzerland, 4 bishops; in Belgium, 1 archbishop and 5 bishops; in France, 14 archbishops and 66 bishops; in Spain, 8 archbishops and 49 bishops; in Portugal, 3 archbishops and 14 bishops; in Russian Poland, 5 archbishops and 13 bishops, of whom 2 archbishops and 3 bishops belong to the united Greek church; in Ireland, 4 archbishops and 23 bishops; in the states of Spanish America, 6 archbishops and 35 bishops; in Brazil, 1 archbishop and 10 bishops; in the Spanish colonies, 1 archbishop and 7 bishops; in the Portuguese colonies, 2 archbishops and 10 bishops; in Hayti, 1 bishop; in the French settlement of Algiers, 1 bishop, lately appointed; in Canada, 2 bishops; in the other English colonies and dependencies, 2 archbishops and 2 bishops; in the United States, 1 archbishop and 11 bishops. (Serristori, *Statistica d'Italia.*) There are besides several bishops in partibus infidelium in Turkey, China, Barbary, &c. In England and other Protestant countries the vicars apostolic exercise the episcopal functions over that part of the community which follows the Roman Catholic faith. The total number of people who profess the Roman Catholic religion in Europe is roughly calculated at about 112 millions, or about one half of the population of Europe. The countries of which the population is exclusively Roman Catholic are,—1, Italy; 2, Spain; 3, Portugal; 4, the kingdom of Belgium. In America, the Spanish and Portuguese states are also exclusively Catholic. Roman Catholic congregations are scattered about various countries of Asia, but in small numbers.

For the manner in which the pope carries on the spiritual government of this extensive flock see CATHOLIC CHURCH and CONCORDAT. The form of election of the pope is given under CONCLAVE. For the history of the popes see their respective names, ADRIAN, ALEXANDER, BENEDICT, BONIFACE, CALIXTUS, CLEMENT, EUGENIUS, FELIX, GREGORY, HONORIUS, INNOCENT, JOHN, JULIUS, LEO, MARTIN, NICHOLAS, PASCHAL, PAUL, PIUS, SERGIUS, SIXTUS, STEPHEN, URBAN, &c. The reader may refer also to the *Vitæ et Res Gestæ Pontificum Romanorum ab Initio nascentis Ecclesiæ usque ad Urbanum VII.*, by Ciaconio, Cabrera, and Vittorello, fol., Rome, 1630.

The chronology of the earlier popes is often obscure, and the dates are uncertain. The following table is chiefly founded on Petau's 'Rationarium Temporum.' According to the chronology of the Roman Church, the apostle St. Peter was the first bishop of Rome, and suffered martyrdom, A.D. 57. He is said to have entrusted in his lifetime the see of Rome to Linus, a native of Etruria, who died in the year 68. Linus was succeeded by Clemens Romanus, who died about A.D. 100. Some chronologists place Anacletus or Cletus between Linus and Clemens, whilst others place him after Clemens. [CLEMENT I.] Evaristus, a native of Palestine, is recorded as bishop of Rome about the year 100, and was succeeded by Alexander I. about 109. Alexander I. was succeeded by Sixtus I., a Roman, in 119. Sixtus was succeeded, in 127, by Telesphorus, a Greek, who is said by Irenæus to have suffered martyrdom about the year 138. Hyginus, a native of Athens, succeeded Telesphorus, and was succeeded, in 142, by Pius I., a native of Aquileia. Pius was succeeded, in 151, by Anicetus, a native of Syria. Anicetus was succeeded, in 161, by Soterus, who was succeeded, in 170, by Eleutherus, in whose time Irenæus visited Rome. Eleutherus was succeeded, in 185, by Victor I., a native of Africa. To Victor succeeded Zephyrinus, A.D. 197. Zephyrinus was succeeded, in 217, by Kallistus or Calixtus I., who governed the see of Rome through a period of comparative tranquillity under the tolerant reign of Alexander Severus. Calixtus was succeeded, in 222, by Urban I. Pontianus succeeded Urban in 230, and died in exile. He was succeeded, in 235, by Antherus, who a few months after his election suffered martyrdom, during the persecution of the Christians by Maximinus. He was succeeded by Fabianus, A.D. 236. Fabianus was succeeded, in 252, by Cornelius, whose election was contested by Novatianus, a Roman presbyter, who is the first antipope recorded in history. Cornelius was succeeded, in 253, by Lucius I. To Lucius succeeded Stephen I., in the same year. Stephen had a warm controversy with Cyprian, bishop of Carthage. Stephen was succeeded by Sixtus II., in 257. Sixtus was succeeded by Dionysius, A.D. 259. It was under Dionysius that the heresy of Paul of Samosata broke out. Dionysius was succeeded by Felix I. in the year 270. Eutychianus succeeded Felix in 275, and was suceeded, in 283, by Caius, who is said to have been a relative of the emperor Diocletianus. Caius was succeeded, in 296, by Marcellinus. Marcellinus died A.D. 305, and after a vacancy of three years Marcellus was elected in 308. Eusebius succeeded Marcellus in 310, who was succeeded in the same year by Melchiades, in whose time Constantine defeated Maxentius and took possession of Rome. Melchiades was succeeded, in 314, by Sylvester I., during whose pontificate Constantine convoked the great council of Nicæa, to which Sylvester sent two priests as his legates. In that council it was decreed that the bishop of Rome should be primate over the churches of those provinces which in civil matters were subject to the jurisdiction of the 'Vicarius Urbis,' or imperial vicar of Rome.

Date of election.
A.D.
336. Marcus, a native of Rome, succeeded Sylvester I.
337. Julius I., a native of Rome.
352. Liberius, a Roman, banished by Constantius.
   Felix, substituted by Constantius, is considered by most as an intruder.
366. Damasus I., a Spaniard, elected after the death of Liberius.
   Ursicinus, antipope against Damasus.
384. Siricius, a Roman, succeeded Damasus.
398. Anastasius I., a Roman.
401. Innocent I., native of Albano.
417. Zosimus, a Greek.
418. Boniface I., a Roman.
422. Celestinus I., a Roman.
432. Sixtus III., a Roman.
440. Leo I. of Rome, called the Great.
461. Hilarius, a native of Sardinia.
467. Simplicius, a native of Tibur.
483. Felix III. of Rome.
492. Gelasius I. of Rome.
496. Anastasius II. of Rome.
498. Symmachus, a native of Sardinia.
514. Hormisdas, a native of Frusino.
523. John I., a Tuscan
526. Felix IV., a native of Beneventum.
530. Boniface II. of Rome.
532. John II. of Rome.

A.D.
535. Agapetus I. of Rome.
536. Sylverius, a native of Campania.
540. Vigilius, a Roman.
555. Pelagius I., a Roman.
560. John III. of Rome.
574. Benedict I. of Rome.
578. Pelagius II. of Rome.
590. Gregory I. of Rome, styled the Great.
604. Sabinianus, a native of Tuscany.
607. Boniface III. of Rome.
608. Boniface IV., a native of Abruzzo
615. Deusdedit or Deodatus I. of Rome.
619. Boniface V., a Neapolitan.
625. Honorius I., a native of Capua.
638. Severinus of Rome.
640. John IV., a native of Dalmatia.
641. Theodorus, a Greek.
649. Martin I. of Tudertum.
654. Eugenius I. of Rome.
657. Vitalianus, a native of Signia.
672. Deusdedit II. of Rome.
676. Domnus I. of Rome.
678. Agathon, a Sicilian.
682. Leo II., a Sicilian.
684. Benedict II. of Rome.
685. John V., a native of Syria.
686. Conon, a native of Thrace.
687. Sergius I., a native of Palermo.
701. John VI., a native of Greece.
705. John VII., a native of Greece.
708. Sisinius, a native of Syria, died a month after.
708. Constantine, a Syrian.
715. Gregory II. of Rome.
731. Gregory III., a Syrian.
741. Zacharias, a Greek, crowned Pepin, king of France.
753. Stephen II. survived his election only a few days.
753. Stephen III. of Rome.
757. Paul I., a Roman.
763. Stephen IV., a Sicilian.
772. Adrian I., a Roman.
795. Leo III., a Roman, crowned Charlemagne emperor, A.D. 800.
816. Stephen V., a Roman.
817. Paschal I., a Roman.
824. Eugenius II., a Roman.
827. Valentinus, a Roman, died in less than two months after.
827. Gregory IV., a Roman.
843. Sergius II., a Roman.
847. Leo IV., a Roman.
   Between Leo and his successor some chroniclers place JOAN.
855. Benedict III., a Roman.
858. Nicholas I., a Roman. Schism of PHOTIUS began.
867. Adrian II., a Roman.
872. John VIII., a Roman.
882. Martin II., called by some Marinus I.
884. Adrian III., a Roman.
885. Stephen VI., a Roman.
891. Formosus, bishop of Porto.
   Sergius, antipope, and after him Boniface, styled by some VI.
896. Stephen VII., a Roman.
897. Romanus, a Tuscan, died after four months.
897. Theodorus II., a Roman, died in less than a month.
897. John IX. of Tibur.
900. Benedict IV., a Roman.
903. Leo V., a native of Ardea.
   Christopher, antipope.
904. Sergius III., the favourite of Marozia and the Tuscan faction.
911. Anastasius III., a Roman.
913. Lando, a native of Sabina.
914. John X., a Roman, died in prison by the Tuscan faction.
928. Leo VI., a Roman.
929. Stephen VIII., a Roman.
931. John XI., son of Sergius III. and of Marozia.
936. Leo VII., a Roman.
939. Stephen IX., a Roman.
943. Martin III., called by some Marinus II.
946. Agapetus II.
956. John XII., Ottaviano Conti, nephew of John XI

A.D.

He was the first who changed his name on his assumption.
963. Leo VIII., styled antipope by some
964. Benedict V., a Roman.
965. John XIII., a Roman.
972. Benedict VI., was killed in the tumult of Crescentius.
973. Domnus II., a Roman.
974. Benedict VII., of the Conti family.
983. John XIV., put to death by Cardinal Franco.
Franco, antipope, by the name of Boniface VIII
985. John XV., a Roman, died in a few months.
986. John XVI., a Roman.
996. Gregory V., a German: Crescentius put to death by Otho III.
999. Sylvester II., Gerbert, native of Auvergne.
1003. John XVIII., a Roman.
1009. Sergius IV., a Roman.
1012. Benedict VIII. of Tusculum, of the Conti family.
1024. John XIX. of Rome, brother of the preceding.
1033. Benedict IX., nephew of the preceding, deposed.
Antipope, Sylvester, bishop of Sabina.
1044. Gregory VI. of Rome, abdicated.
1047. Clement II. of Saxony (bishop of Bamberg).
1048. Damasus II. (Poppo, bishop of Brixen).
1049. Leo IX., bishop of Toul. Final separation of the Greek church.
1055. Victor II., bishop of Eichstadt.
1057. Stephen IX. Frederick, abbot of Monte Casino
1058. Benedict X., by some styled antipope, abdicated.
1059. Nicholas II. of Burgundy.
1061. Alexander II. of Milan.
1073. Gregory VII., Hildebrand, a monk of Soana in Tuscany.
Guibert, antipope, assumed the name of Clement III.
1086. Victor III., a native of Beneventum.
1088. Urban II., a native of France.
1099. Paschal II., a native of Tuscany.
Antipopes, Albert and Theodoric.
1118. Gelasius II., a native of Caieta.
1119. Calixtus II., a native of Burgundy.
1124. Honorius II., Cardinal Lamberto, bishop of Ostia.
1130. Innocent II., a Roman.
Anacletus, antipope.
1143. Celestinus II., a Tuscan.
1144. Lucius II. of Bologna.
1145. Eugenius III. of Pisa.
1153. Anastasius IV., a Roman.
1154. Adrian IV., Nicholas Breakspeare, an Englishman.
1159. Alexander III. Cardinal Orlando Bandinelli of Siena.
Cardinal Octavian, antipope, by the name of Victor.
Cardinal Guido, antipope, by the name of Paschal.
Calixtus, antipope.
1181. Lucius II., Cardinal Ubaldo of Lucca.
1185. Urban III., Uberto Crivelli, archbishop of Milan.
1187. Gregory VIII. of Beneventum, died in two months.
1188. Clement III., Paul, bishop of Præneste.
1191. Celestinus III., Cardinal Hyacinthus, a Roman.
1198. Innocent III., Cardinal Lotharius of Signia.
1216. Honorius III., Cardinal Savelli of Rome.
1227. Gregory IX., Cardinal Hugo of Anagni.
1241. Celestinus IV. of Milan, died in a few days.
1242. Innocent IV., Cardinal Sinibaldo Fieschi of Genoa.
1254. Alexander IV., Cardinal Rinaldo Conti of Anaqui.
1261. Urban IV., James, patriarch of Jerusalem, a Frenchman.
1265. Clement IV., Guy of St. Gilles in Languedoc.
1272. Gregory X., Tebaldo Visconti of Piacenza.
1276. Innocent V., Cardinal Peter, a native of Tarentaise.
1276. Adrian V., Ottobono Fieschi of Genoa, died in a month.
1276. John XXI. of Lisbon.
1277. Nicholas III., Cardinal Orsini of Rome.
1281. Martin IV., Cardinal Simon de Brie, a Frenchman.
1285. Honorius IV., Cardinal James Savelli of Rome.
1288. Nicholas IV., Cardinal Jerome of Ascoli.
1294. Celestinus V., Pietro da Morrone of Abruzzo, abdicated.
1295. Boniface VIII., Cardinal Benedetto Caetani of Anagni.
1303. Benedict XI., Cardinal Nicholas of Treviso.
1305. Clement V., Bertrand of Bordeaux, removed the Papal See to Avignon.
1316. John XXII., James of Cahors in France.

A.D.

Nicholas, antipope, in Italy.
1334. Benedict XII., James Fournier, a Frenchman.
1342. Clement VI., Peter Roger of Limoges in France.
1352. Innocent VI., Stephen Aubert of Limoges.
1362. Urban V., William Grimoard, a Frenchman.
1370. Gregory XI., Peter Roger, a Frenchman, restored the Papal See to Rome.
1378. Urban VI., Bartolomeo Prignano, a Neapolitan.
Antipope, Clement, at Avignon.
1389. Boniface IX., Peter Tomacelli of Naples.
Antipope, Pedro de Luna, a Spaniard. [BENEDICT, ANTIPOPE.]
1404. Innocent VII., Cosmo Migliorati of Sulmona.
1406. Gregory XII., Angelo Corrari of Venice, abdicated at Constance.
1409. Alexander V., Peter Philargius of Candia.
1410. John XXIII., Cardinal Cossa, deposed by the Council of Constance.
1417. Martin V., Otho Colonna, a Roman.
1431. Eugenius IV., Gabriel Condulmero, a Venetian
Schism between the Pope and the Council of Basle.
Felix, antipope. [AMADEUS VIII.]
1447. Nicholas V., Cardinal Thomas of Sarzana
1455. Calixtus III., Alfonso Borgia, a Spaniard.
1458. Pius II., Æneas Sylvius Piccolomini of Siena
1464. Paul II., Peter Barbo of Venice.
1471. Sixtus IV., Francis della Rovere, a Genoese
1485. Innocent VIII., Gian Battista Cibo, a Genoese.
1492. Alexander VI., Rodrigo Lenzoli Borgia, a Spaniard.
1503. Pius III., Francis Todeschini Piccolomini, died in a month.
1503. Julius II., Julian della Rovere, a Genoese.
1513. Leo X., Giovanni de' Medici, son of Lorenzo the Magnificent.
1522. Adrian VI. of Utrecht, preceptor of Charles V.
1523. Clement VII., Giulio de' Medici, nephew of Lorenzo.
1534. Paul III., Alessandro Farnese of Rome: convoke the Council of Trent.
1550. Julius III., Giovan Maria Giocci of Rome.
1555. Marcellus II., Cardinal Cervini of Montepulciano, died in a month.
1555. Paul IV., Gianpietro Caraffa, a Neapolitan.
1559. Pius IV., Giovanni Angelo Medichini of Milan closed Council of Trent.
1566. Pius V., Michele Ghislieri of Alessandria in Piedmont.
1572. Gregory XIII., Hugo Buoncompagni of Bologna.
1585. Sixtus V., Felice Peretti of Montalto in the March of Ancona.
1590. Urban VII., Gian Battista Castagna, a Genoese, died in a few days.
1590. Gregory XIV., Nicola Sfrondati of Milan.
1591. Innocent IX., Gian Antonio Facchinetti of Bologna.
1592. Clement VIII., Ippolito Aldobrandini, a native of Fano.
1605. Leo XI., Alessandro de' Medici of Florence, died in a month.
1605. Paul V., Camillo Borghese of Rome.
1621. Gregory XV., Alessandro Ludovici of Bologna.
1623. Urban VIII., Maffeo Barberini, a Florentine.
1644. Innocent X., Gian Battista Pamfili of Rome.
1655. Alexander VII., Fabio Chigi of Siena.
1667. Clement IX., Giulio Rospigliosi of Pistoia.
1670. Clement X., Emilio Altieri of Rome.
1676. Clement XI., Benedetto Odescalchi of Como.
1689. Alexander VIII., Pietro Ottoboni of Venice.
1691. Innocent XII., Antonio Pignatelli of Naples.
1700. Clement XI., Gian Francesco Albani of Urbino.
1721. Innocent XIII., Michel Angelo Conti of Rome.
1724. Benedict XIII., Vincenzo Maria Orsini of Rome.
1730. Clement XII., Lorenzo Corsini of Florence.
1740. Benedict XIV., Prospero Lambertini of Bologna.
1758. Clement XIII., Carlo Rezzonico of Venice.
1769. Clement XIV., Gian Vincenzo Ganganelli, born near Rimini.
1775. Pius VI., Angelo Braschi of Cesena.
1800. Pius VII., Gregorio Barnaba Chiaramonti of Cesena.
1823. Leo XII., Annibale della Genga, native of Romagna.
1829. Pius VIII., Cardinal Castiglioni of Cingoli.
1831. Gregory XVI., Mauro Capellari, born at Belluno.

POPERY is a word often used in England in an invidious sense to denote the Roman Catholic religion in general, but more particularly those tenets of the Roman church which are most obnoxious to those who dissent from it, such as its avowed exclusiveness, its intolerance, which is founded on the belief that out of its pale there can be no salvation, and its consequent authoritative tone and determined proselytism. For a zealous Catholic there can be no truce with what he considers to be error, and his duty is to reclaim as many as he can to the bosom of his church.

In an encyclic letter of the present pope, dated 15th August, 1832, and addressed to all patriarchs, archbishops, and bishops, the principle of allowing liberty of conscience to the people is censured as 'absurd, erroneous, and delirious, derived from the corrupt source of indifferentism. For the liberty of error is death to the soul.' It was in compliance with this declaration that La Mennais in the following September dissolved the society which he had established 'for advocating religious liberty.' (*Affaires de Rome*, par M. F. de la Mennais, Bruxelles and London, 1836, with copy of the 'Encyclic Letter,' and other documents.)

POPERINGEN is a flourishing town in the province of West Flanders, in the kingdom of Belgium, twenty-six miles south by west of Ostend, situated on a canal called the Schipvaert, and has 10,000 inhabitants. The churches, of which there are seven, viz. two parish churches and five belonging to the convents, are well-built edifices. The inhabitants have considerable manufactures of coarse woollens and serge, several oil-mills, and carry on a profitable trade, especially in hops, which are very extensively cultivated in the neighbouring country, and are of very superior quality, being preferred even to those of Alost. (Stein; Hassel.)

POPPY. [PAPAVER.]

POPULATION, the number of people in any country or division of a country, or in a city or town.

The circumstances which determine the proportion of the population to the area of any given country, are the first elements which we must take into the account in considering their social condition. In the lowest stage of human existence, that in which men depend on hunting and fishing for a subsistence, they are scattered over an immense surface in order to obtain food; and as the animals which they pursue become scarce in one part, they remove to another. Though the numbers of a tribe may not average one individual to a square mile, the difficulties of procuring subsistence are often so great, that frequent hunger and occasional famines have always characterised the savage state. Many of the tribes of North America which live near and among the Rocky Mountains are actual examples of this precarious mode of existence; and the white men who hunt the fur-bearing animals in the same regions are subjected to these inconveniences of a savage life. The purely pastoral state admits of a greater relative proportion of population; but the necessity of frequent removal from place to place in search of pasture does not admit of this proportion surpassing a certain limit, which is determined by the capabilities of the uncultivated land to feed their flocks and herds. If agriculture be resorted to, and the occupation of the shepherd be exchanged for that of the husbandman, the tract over which the former wandered with their flocks will sustain a much larger population. In the early stages of agriculture, the implements of labour are few and imperfect; the clothing of each family is the produce of household industry; and only a limited number of non-agriculturalists is needed to satisfy the demands of the community. When a more minute division of employments takes place; and the husbandman is solely engaged in raising food, while others are employed in making clothing and supplying all the other wants of the population, the labour of the community becomes much more productive, and food being consequently raised in greater quantities, this change is followed by an increase of the population; and when machines for abridging human labour are introduced, a further stimulus is given to the increase of population. An intelligent, healthy, and industrious population, who possess a good soil and abundance of mineral wealth, are enabled by improvements in machinery and labour-saving contrivances, not only to supply their own wants, but those of other countries in a less advanced state. When a country has succeeded in introducing the products of an extensively diversified industry into the markets of the world, and thus enjoys a far larger amount of commerce than it could command if its foreign trade were determined by the mere extent of its territory, instead of the industry, enterprise, and intelligence of its inhabitants operating on its natural resources, the population may be increased almost indefinitely, with a continual increase in the comforts which it enjoys. In the savage state, a tract of several hundred square miles is overstocked by as many individuals: in nations which have reached the highest degree of civilization hitherto known, the population is as great to one single square mile.

Under all the diversity of circumstances in which the inhabitants of different parts of the world exist, their numbers are limited by the means of subsistence. If the population increases faster than the food for their support, poverty and misery ensue, and death thins their numbers, and brings them to a level with the means of subsistence. This effect may take place whether the population be one to a square mile or several hundreds. Hence the proportion of births, marriages, and deaths to the population, is as important an element in ascertaining the physical condition of the population of any country as the proportion of their numbers to each square mile.

The evils which arise when the population increases more rapidly than the means of subsistence had not escaped the notice of two of the most eminent writers of antiquity Plato and Aristotle. (Plato, *Laws*, v., and *Republic*, v.; Aristotle, *Politik*, vii. 16.) In later times, this truth had been seen by Dr. Franklin, Sir James Stewart (*Treatise on Pol. Econ.*, book 1), Mr. Townsend (*Essay on the Poor-Laws*), and other English and French economists. Their views attracted little attention at the time when they wrote. In England especially, during the eighteenth century, a false opinion prevailed that the population was diminishing; and subsequently the demand for men during the long war with France rendered the evils of a redundant population almost imaginary in general estimation. The decennial census of the population during the present century, the transition from war to peace, and the commercial embarrassments and periods of public distress which have been experienced, have contributed to enlighten the public mind; and the writings of the late Mr. Malthus have powerfully aided in producing correct views upon the questions of population. His 'Essay on the Principle of Population' was first published anonymously in 1798. This work was suggested by a paper in Godwin's 'Inquirer,' and the author's object was to apply the principle of population in considering the schemes of human perfectibility, and other speculations on society to which the French revolution had given birth. Hume (*Populousness of Ancient Nations*), Wallace (*Dissertation on the Numbers of Mankind in Antient and Modern Times*), and Dr. Price's writings of more recent date, were the authors from whom Mr. Malthus deduced the main principle of his Essay. In 1803 appeared a second edition, to which Mr. Malthus affixed his name, and which might almost be considered as a new work. The author had in the interval directed his attention to an historical examination of the effect of the principle of population on the past and present state of society, and the subject was for the first time treated in a comprehensive and systematic manner. A third and fourth edition appeared a few years afterwards. The fifth edition, containing several additional chapters, was published in 1817. The sixth and present edition, which contained few alterations, was published in 1826. The title of the work as it at present stands is as follows:—'An Essay on the Principle of Population, or a view of its past and present Effects on Human Happiness, with an Inquiry into our prospects respecting the future removal or mitigation of the evils which it occasions.' The following is a brief summary of its leading principles.—Mr. Malthus's propositions are—that population, when unchecked, goes on doubling itself every twenty-five years, or increases in a geometrical ratio; while the means of subsistence, under the most favourable circumstances, could not be made to increase faster than in an arithmetical ratio. That is, the human species may increase as the numbers 1, 2, 4, 8, 16, 32; while the increase of food would only proceed in the following ratio, 1, 2, 3, 4, 5, 6. Thus if all the fertile land of a country is occupied, the yearly increase of produce must depend upon improved means of cultivation; and neither science nor capital applied to land could create an increased amount of produce beyond a certain limit. But the increase of population would ever go on with unabated vigour, if food could be obtained, and a population of twenty millions would possess as much the inherent power of doubling itself as a population of twenty thousand. Population however cannot increase beyond the lowest nourishment capable of supporting life; and therefore the difficulty of obtaining food forms the primary check on the increase of population, although it does not usually present itself as the immediate check, but operates upon mankind in the various forms of misery or the fear of misery. The immediate check may be either *preventive* or *positive;* the former being such as reason and reflection impose, and the latter consisting of every form by which vice and misery shorten human life. Thus a man may restrain the dictates of nature which direct him to an early attachment for one woman, from the fear of being unable to preserve his children from poverty, or of not having it in his power to bestow upon them the same advantages of education which he had himself enjoyed. Such a restraint may be practised for a temporary period or through life, and though it is a deduction from the sum of human happiness, the evil is not to be compared in extent with that which results from the positive checks to population, namely, unwholesome occupations, severe labour, and exposure to the seasons, extreme poverty, bad nursing of children, excesses of all kinds, the whole train of common diseases and epidemics, wars, plagues, and famines.

The preventive and the positive checks which form the obstacles to the increase of population are resolvable into, 1, moral restraint; 2, vice; and 3, misery. *Moral restraint* (considered as one of the checks to population for the first time in the second edition, 1803) is the prudential restraint from marriage, with a conduct strictly moral during the period of this restraint. Promiscuous intercourse, unnatural passions, violation of the marriage bed, and improper arts to conceal the consequences of irregular connections, are included under the head of *Vice.* Those positive checks which appear to arise unavoidably from the laws of nature may be called exclusively *Misery.* Such are the checks which repress the superior power of population, and keep it on a level with the means of subsistence.

The 'Essay on Population,' as the following analysis of its contents will show, places the question in every light which can elucidate the truth. It is divided into four books, the first of which notices the checks to population in the less civilised parts of the world and in past times. The second book passes in review the different states of modern Europe (most of which Mr. Malthus visited in the interval preceding the publication of the second edition), and he points out the checks to population which prevail in each. Chapter xi. of this book is 'On the Fruitfulness of Marriages;' chapter xii. 'On the Effects of Epidemics on Registers of Births, Deaths, and Marriages; and chapter xiii. is devoted to 'General Deductions from the preceding view of Society.' The third book comprehends an examination of the different systems or expedients which have been proposed or have prevailed in society, as they affect the evils arising from the principle of population; in the first three chapters, the systems of equality proposed by Wallace, Condorcet, Godwin, &c. are considered. Several chapters are devoted to the consideration of poor-laws; corn-laws (first in connection with bounties on exportation, and secondly under restrictions on importation); the agricultural system; the commercial system; and the combination of both. The last two chapters are, 'Of increasing Wealth as it affects the Condition of the Poor;' and a summary containing 'General Observations.' The fourth book treats of 'Our Future Prospects respecting the Removal or Mitigation of the Evils arising from the Principle of Population.' Chapter i. treats 'Of Moral Restraint and our Obligations to practise this Virtue.' Chapter ii. is 'Of the Effects which would result to Society from the prevalence of Moral Restraint.' Chapter iii. is 'Of the only effectual Mode of Improving the Condition of the Poor.' And the last chapter is 'Of our rational Expectations respecting the Future Improvement of Society.'

Perhaps no author has been more exposed to vulgar abuse than Mr. Malthus. He was accused of hardness of heart, and represented as the enemy of the poorer classes, whereas no man was more benevolent in his views; and the earnestness with which he engaged in his work 'On Population' arose from his desire to diminish the evils of poverty to their lowest possible amount. His mind was philosophic, practical, and sagacious; his habits, manners, and tastes, simple and unassuming; his whole character gentle and placid. The last edition of his 'Principles of Political Economy' contains an interesting memoir of his life and writings by Dr. Otter, late Bishop of Chichester, who had known him intimately for half a century. A list of Mr. Malthus's works and writings is given in page 42 of this 'Memoir:' it is a matter of regret that they have never been published in a collected form. Several of the most valuable productions of his pen appeared in the Edinburgh and Quarterly Reviews. We must refer the reader to the above 'Memoir' for a further account of Mr. Malthus. He was born at Albury, near Guildford, in 1766; was a fellow of Jesus College, Cambridge, and entered holy orders: he afterwards married. In 1804 he was appointed Professor of History and Political Economy at the East India College, Haileybury, the duties of which he fulfilled to the time of his death, in December, 1834. Mr. Malthus was a Fellow of the Royal Society and member of the National Institute of France. It is not creditable to those who had the distribution of ecclesiastical patronage, that Mr. Malthus never held any preferment in the church. From this brief notice of the individual whose name is so intimately identified with the theory of population, to the elucidation of which the best part of his life was devoted, we turn to the subject of the present article.

Although circumstances may sometimes occur in which the tendency of population to outstrip the means of subsistence may be counteracted, and food may for a time increase faster than population, yet this only gives an impulse to the latter, and the former proportion is quickly re-established provided no improvement takes place either in the prudential habits of the people or in the elevation of their tastes and desires. The poverty and misery which are observable among the lower classes of the people in every country can in a great degree be accounted for by a reference to the principle of population. It is evident, for example, that the rate of wages depends, for one of its elements, on the proportion between population and means of employment, or in other words, capital; and that any alteration in either directly affects wages. If population has increased while the funds for employing labour have remained stationary, the competition of labourers will cause the rate of wages to decline. If, on the other hand, capital has increased faster than population, or capital has been concentrated on any given spot more rapidly than population, wages will rise in the former case, and in the latter will be higher than in other places where the same thing has not taken place. Thus, occasionally in some parts of the United States, so many emigrants with capital will flock to a single spot, that the wages of carpenters, tailors, and others, whose labour is in immediate demand, will become very high compared with any other place that has not been recently settled. The tendency of population to increase is the same under all circumstances, but this is not the case with capital; for in proportion to the capital already accumulated, the difficulty of adding to it becomes greater, that is, the field for the employment of capital becomes less extensive. Under such circumstances wages would have a constant tendency to fall, if the checks to population did not interpose; but it depends upon the people themselves whether the level is to be maintained by vice and misery, or by habits of prudential restraint. The latter may always be depended upon for securing to them a fair proportion of the necessaries of life.

The great problem of society is to maintain the most beneficial proportion between population and food—'to unite the two grand desiderata, a great actual population and a state of society in which squalid poverty and dependence are comparatively but little known.' Disheartening as the evils resulting from the principle of population may at first sight seem, they are capable of mitigation. This principle may even be regarded as one of the great springs of human improvement—as the parent of invention and the stimulus to exertion—which preserves society from that state of imbecility and decline into which it would fall if not urged onward by some extraordinary power. It is the interest of all members of society, and is particularly incumbent on those who have the power, to use their best exertions to elevate the habits, tastes, and moral feelings of the people; and by this means to render every successive material improvement conducive to the happiness of society. If this be not done, as much wretchedness as we find in the lower stages of society may co-exist with the highest efforts of art and science and the greatest perfection in all the processes of industry. Even the introduction of vaccination or any similar means of diminishing mortality is of little avail provided the number of marriages continues the same without any corresponding increase of the resources of society, and the average mortality will not be diminished, but disease will be fatal under other forms. Every improvement which tends to increase the quantity of human food, and every invention which enriches society by cheapening the processes for obtaining the necessaries of life should be accompanied by a corresponding advance in the intellectual and moral character of a nation, in order to secure all the advantages which these improvements are calculated to confer.

Mr. Malthus's theory is now generally accepted as the true exposition of the principle of population. Many of the objections that have been urged against it are hardly worthy of notice. Some are content to quote the Scripture command, 'Increase and multiply,' forgetful of the moral obligations which are imposed in connection with it. Others have imagined that they have discovered a supernatural law of fecundity which varies with the fluctuating circumstances of society. Dr. Price, Mr. Godwin, and Mr. Sadler entertained this notion. Mr. Malthus's reasons for not replying to Mr. Godwin's work are stated in the appendix to the sixth edition of the 'Essay on Population.' The fallacies of Mr. Sadler's work are most ably exposed in the 'Edinburgh Review,' No. 102. Mr. Senior is the only economist of any distinction who has objected to the theory of Mr. Malthus. He contends, in his 'Two Lectures on Population,' for the doctrine that 'the means of subsistence have a natural tendency to increase faster than population.' The appendix to these 'Lectures' contains a correspondence between Mr. Malthus and Mr. Senior on their respective views: it exhibits the latest views of Mr. Malthus, though, after forty years' anxious reflection on the subject, he had no change to make in his opinions. The latest work on population (published in the middle of 1840) is 'The Principles of Population, and their Connection with Human Happiness,' by Archibald Alison, Esq.

The disputes about the principle of population, like those which have arisen in many other questions of a like kind, are mainly owing to the ambiguity of language: in fact they are very little more than questions about the consistent use of words. If we analyse the proposition of Mr. Senior, it will appear that it is not easy to conceive with clearness the meaning of its terms. The words 'means of subsistence' may signify the subsistence which is obtained from spontaneous products of the earth and from the natural increase of animals. The products of the earth may be said to have a natural tendency to increase, or naturally to increase, or rather to be produced; and it may, for argument's sake, be admitted, though it is not true, that animals have the same kind of natural tendency to increase, or are in like manner naturally increased, or rather are produced. There is no other natural tendency to increase, or natural increase, or natural produce, that we can conceive, if the word 'natural' is to have its ordinary acceptation. The increase of population, or the produce of new population, may be said to be natural, exactly in the same sense in which the increase or produce of animals generally may be called natural. If then this should be the sense of the word 'natural,' the proposition means that vegetables and animals (not including man) have a natural tendency to increase faster than man, who is also an animal—a proposition which is not worth the trouble of discussion.

But this is not the meaning of the writer who maintains this proposition: he is evidently speaking of human labour and its products when he is speaking of the 'means of subsistence.' The term 'means of subsistence' therefore contains the notion of human labour; and 'means of subsistence' are the products obtained by human industry applied to material objects. Everything 'natural' therefore is by the very force of the term 'means of subsistence' excluded from these words; for it is not of natural produce simply that the writer is speaking, but of that which human labour produces: in other words, though nature (to use the vulgar term) co-operates, the thing produced is not viewed as nature's product, but as the product of human labour. There is then nothing 'natural' in 'the means of subsistence,' and therefore there is no natural tendency to increase in the means of subsistence; and consequently the comparison contained in the proposition between things that have no natural tendency to increase, and things that, in a sense, have a natural tendency, is unmeaning. Whether then the assertion be that 'there is a natural tendency in population to increase faster than capital' (Mill), or 'that the means of subsistence have a natural tendency to increase faster than population' (Senior), in either case the use of the word 'natural' is incorrect, and not only tends to cause, but does cause confusion. It should be observed that in enunciating this proposition, Mr. Senior sometimes omits the word 'natural.'

Again, the natural tendency of population to increase is simply the desire and the power to gratify the animal passion, the consequence of which is the physical union of the sexes and the production of their kind. But this tendency (to use again this very vague expression) is positively checked by want of food and other things necessary for human sustentation and health. If food and such other things could be had to an indefinite amount without any labour, so far as food and such other things only are necessary to its increase, population would go on continually increasing. But the actual conditions of obtaining food and such other things are human labour; that is, the labour of those animals, who, if supplied with all that they want without any labour, *might* go on increasing indefinitely. It appears then that this so-called natural tendency of population to increase has no *effect*, that is, it remains a tendency; that is, it is nothing at all in results, unless man labours; and the amount of his labour, in considering this question, is quite immaterial. It is unimportant whether it consists in making a plough and ploughing the earth, or plucking an apple from a tree and eating it. The whole proposition then may be developed thus:—The means of subsistence are only produced or had by man's labour: these 'means of subsistence' so produced have no natural tendency to increase, except so far as man has a natural tendency to increase. Now, man has in a sense a natural tendency to increase, that is, he has a desire and a capacity to increase, and he can increase if he has the means of subsistence. But he must have the means of subsistence first; and if the actual means of subsistence are only sufficient for the actual population, there can be no increase of the population till the means of subsistence are increased. The 'means of subsistence,' at any given time and in any given nation, signify those things which the individuals of that nation require according to their several stations and the habits of society: they may be the bare means of sustaining life; or they may be those things also which Mr. Senior has well defined under the heads of 'decencies' and 'luxuries.' If, while the means of subsistence remain the same, the population lower their scale of living, it may increase further, for the relative means of subsistence are by the supposition increased. It is true that this lowering of the scale of living is an evil, inasmuch as it tends to make society move in a retrograde direction: there is also a limit to the extent to which the scale of living can be lowered. The antecedent condition then on which the increase of population depends is its own labour, for it cannot increase without the increase of the means of subsistence, and such increase is the effect of labour only.

We can never contemplate human society in its origin. We must contemplate it in its progress and development. All theories as to how man *began* to propagate and gain the means of subsistence are useless towards the solution of any problem that concerns his condition. We know this, and no more: at any given time and in any given state of society there is a certain population which subsists in a certain mode by and out of the means of subsistence which it then has; and these means are partly the product and accumulation of the actual generation and partly the accumulation of their progenitors. If the means of subsistence (thus understood) of that population are sufficient, and no more than sufficient, any increase of the population must be preceded by increased labour, or by labour rendered more productive. We cannot suppose the population to increase first, and then the additional means of subsistence to be produced; for by the supposition the actual population has only sufficient, and that which is 'increase' must be fed out of some other store.

If it is said that children may be born and die immediately, or very soon, the answer is, they either die before they have partaken of the means of subsistence, in which case they no more enter into the reckoning than 'means of subsistence' produced but not enjoyed, because from some accident or cause these 'means' perished before they could be used; or the children did live to partake of the means of subsistence, in which case they are properly included in the word 'increase.'

Now the fact is, that in some countries the means of subsistence are barely sufficient for the existence of the actual population; in others they are more than barely sufficient. In the former case there can be no increase of population until there has first been an actual increase, in the means of subsistence; in the latter there may be an increase of the population before there is an increase of the means of subsistence, and this increase of population may go on without any increase in the means of subsistence, until the people have reached the lowest limit of subsistence.

It is clear then that the 'means of subsistence' (as above explained) must be first, and increase of population may then follow, and generally does follow to the full amount of these increased means of subsistence; and further, population may and sometimes does increase beyond the amount of such increased means, but it is then of necessity checked by actual suffering in the whole or in a part of the society. And this, we conceive, is the meaning of Mr. Malthus's proposition.

There seems to be an error (or rather, looseness of expression in most writers) in the mode of comparing the rate of increase of the two things, 'means of subsistence' and 'population.' There can be no useful comparison of the rate of increase between these two things except this: a given population may attain its increase, which is proportionate to the antecedent increased means of subsistence, in a less time than these increased means of subsistence were produced; or it may take a longer time. There is also no question about a *tendency* to increase either in the one thing or the other; the question is about an actual increase, which can only take place under the conditions already stated.

The question is perplexed, and its true statement rendered difficult by the fact that an increase of the whole means of subsistence and an increase of the population may be, and generally are, going on at the same time; and it seems to have been supposed that this increase of population, during a given time, is owing to the *then* increasing means of subsistence. But this cannot be true if it shall be admitted that a given amount of population cannot be increased, unless the actual amount of the means of subsistence of that population is first increased, or, which is the same thing, the rate of living is reduced. If some writers on this subject have not meant what is here imputed to them, they have certainly not sufficiently guarded themselves against the imputation.

There is still another consideration which perplexes the question. For very short periods it is certainly conceivable, and it is very probably the case, that sometimes population is increasing (in a certain sense) at a faster rate than the means of subsistence; that is, taking short intervals, it will or may be found that the population, during such intervals, has outstripped the means of subsistence existing at the end of such intervals, and a part of it must therefore die. These deaths consequently take place either in the whole population, or among those whose means of subsistence are reduced; for some parts of the community may and do enjoy, under such circumstances, as much as they did before, while others do not. In practice, a deficient allowance is not distributed among all, but some suffer and others do not. But on the other hand it is conceivable, and it may be true, that for short intervals the means of subsistence may sometimes be increasing more rapidly than the contemporaneous increase of population; that is, the actual population may possess and be producing and accumulating the means of subsistence more than sufficient for the sustentation of themselves and of the addition to the population made during the time of such production and accumulation. Now this is certainly the fact in many societies, as to part of the society; one part is producing and accumulating more than is necessary for the increase of the population which it is producing: this is the case with many of the middle classes in all industrious communities. At the same time another class is increasing its population at a greater rate than the means of subsistence applicable to such increase: the check to such an increase is obvious. There is no reason why this may not be true of a whole population, as it is of a part.

On the whole, the experience of mankind proves that the sexual passion will, if unrestrained, always increase the population by new births up to the level of the means of subsistence at each moment existing; while the appetite for labour, by which the means of subsistence are produced, is easily satisfied. It would not seem strange then, if during short intervals the propagation of the species has been so active as to have outstripped the means of subsistence existing at the end of such intervals. But though the population during short intervals may so increase, its increase at the end of a series of such consecutive intervals can only be the effect of a previous increase in the means of subsistence; always supposing the condition of the people not to be growing worse, for there may be, as already observed, an increase of population up to the limit of a bare subsistence, without any actual increase in the whole means of subsistence. Therefore the increase of the means of subsistence, that is, the products of human labour, are the antecedent conditions of any actual increase, and the increase of population may be to the amount of such increase, but cannot surpass it. If for short periods the increase of population does surpass the increase on which by the supposition it depends, the increase is checked; and on taking the account at longer intervals, there is, or may be, no actual increase of the population. If for short periods the increase of the means of subsistence surpasses the increase of population, this is made up in the next periods by an increase in the population. There is then, or may be, a constant fluctuation for short periods, the population and the means of subsistence alternately increasing with greater rapidity. But any increase of population, even for a short period, supposes a previous increase of the means of subsistence over those which the actual population found to be merely sufficient before the commencement of such short period; whatever may be the comparative rates of increase between the two during such short period. It seems then that in the sense here explained population may so rapidly increase that at the end of an interval from the commencement of which the increase of population is reckoned, the means of subsistence existing at the commencement of such interval, and which were sufficient for the then population and something more, added to the means of subsistence produced during such interval, may be insufficient to support the population existing at the end of such interval, in the same way in which the population existing at the commencement of such interval was living; and, on the other hand, the means of subsistence existing at the end of such interval may be more than sufficient to support the population existing at the end of such interval in the same way of living. At the end of any long interval, if there is an increase of population, as compared with the commencement of such interval, there has been during such interval, on the whole, a balance on the side of the means of subsistence, provided the mode of living has not been lowered; and à fortiori, there must have been such balance, if the mode of living has been raised; that is, the means of subsistence at the commencement of such interval, and those produced during it, have been sufficient to produce and leave in existence at the end of such interval, a larger population than at the commencement of it. This excess on the side of the means of subsistence, if distributed equally through every moment of the long interval, would leave at the end of each such interval a surplus of subsistence, the antecedent condition of an increase in the following interval. The actual fact may be that in some intervals population has passed a little beyond what was provided at the beginning of and during such intervals, the consequence of which is a diminution in its rate of increase in the next interval, and sometimes an increase of deaths. In discussing this question, it is always actual increments that are to be considered, and both for short and long periods. The tendency is nothing; for a tendency of any kind, that is, a capacity to or for a given end, means nothing in such speculations as these, unless it becomes an effect.

The principle of population is stated by Mr. Malthus with more precision than by some writers who have adopted his opinions; and though it seems to us that his language is not always quite free from objection, his real meaning is perfectly so. His correspondence with Mr. Senior shows this. The importance of right notions on this subject must be our apology for this further attempt at explaining it.

PO'PULUS. [ROME.]

PORCELAIN. [POTTERY.]

PORCELLA'NA, Adanson's name for the testaceous form known to modern zoologists by the name of *Marginella*. The name is now in general use for a genus of *Crustacea*. [PORCELLANIANS.]

PORCELLA'NIANS, a tribe of *Anomurous Crustaceans*, placed by M. Milne Edwards next to the *Pagurians*, and immediately preceding the section of *Macrurous Decapods*.

M. Milne Edwards observes that this small tribe is principally composed of crustaceans which have quite the port of the *Brachyura*, but which are distinguished from all the *Decapods* of which that author had previously treated by their fan-like caudal fin, more or less resembling that of the *Macrura*. He states that he only knows a single genus having this conformation, viz. the *Porcellanæ*. He has however thought fit to arrange in the same division *Æglea*, which establishes the passage between the *Porcellanæ* and the *Galatheæ*, and which have hitherto been approximated to the last, as well as *Megalops*, which form is perhaps nothing but the young state of some genus of the preceding family, whose development is not complete. To distinguish between these three genera it is sufficient to recollect that in the *Porcellanæ* and the *Ægleæ*, the fifth pair of feet are filiform and bent back above the others, whilst in *Megalops* they are formed like them, and that the *Ægleæ* have the body elongated and the abdomen very stout, whilst the *Porcellanæ* have the body nearly circular and the abdomen very delicate. Provisionally, M. Milne Edwards arranges *Monolepis* of Say in this tribe, which form M. Milne Edwards says that he has not examined, but which he thinks ought to be considered as young crustaceans whose true characters are not known.

Porcellana. Lam.

Generic Character.—General form resembling that of the *Brachyura*. *Carapace* ordinarily as wide as it is long, suborbicular and depressed above. *Front* advanced above the insertion of the internal antennæ, and even capable of covering them completely when they are bent back, without there being, nevertheless, antennary fossets. *Eyes* small and lodged in a sort of *orbit*, the upper wall of which is well formed, but the limits of which are not determined externally and internally except by the antennæ, and whose inferior border is very short and scarcely projecting: this last border is prolonged externally, and there is between the kind of crest thus formed and the border of the carapace a deep furrow, from which the *external antenna* springs; these appendages are inserted consequently outside the eyes; their basilary portion is composed of three cylindrical joints, the second of which is the greatest, and their terminal stem is very long. The *buccal frame* is quadrilateral, but much too small to receive the external *jaw-feet*, which, in bending back, are applied against the lower border of the front. These last appendages are very large; their second joint presents on the internal side a large lamellar dilatation with rounded borders, and its anterior and external angle is prolonged so as to form a more or less stout tooth; the third joint is much smaller and nearly triangular; the joints which follow diminish successively, and are furnished internally with very long hairs; there is also, as ordinarily, an external stem or pulp, terminated by a small multi-articulate filament, but there is no *flagrum*. The *sternal plastron* is very wide and nearly circular. The anterior *feet* are very large and more or less flattened; the arm is very short and never reaches much beyond the carapace; but the carpus is very long, and presents in general a lamellar prolongation, which advances above the superior border of the hand when it is bent back. The pincers are strong, and little or not at all dentated. The three succeeding pairs of feet are nearly cylindrical, and terminated by a conical tarsus; the last pair are very slender, bent back above the base of the others, and terminated by a small didactylous pincer. The *abdomen* is wide but lamellar, and bent below against the sternum; it is composed of seven distinct rings in a large fan-shaped fin consisting of five blades, and formed by the last segment and by the appendages of the preceding ring; the basilary piece of these appendages is very short, and carries two great oval blades nearly of the same size, ciliated on their edges, and divided backwards. The median piece of this fin does not reach beyond the lateral appendages, and presents furrows which seem to indicate that it is formed by the soldering of the seventh abdominal ring with a pair of lamellar appendages belonging to this same segment. The underside of the abdomen is more or less membranous, and presents in the male a single pair of appendages fixed to the second ring, and each composed of a small cylindrical stem terminated by an oval lamella. In the female are found two or three pairs of oviferous feet, which are fixed to two or three rings which precede the penultimate ring, and each composed of a multi-articulate stem. Lastly, the *branchiæ* are fourteen on each side, and are disposed in bundles of two above the external jaw-foot and the anterior foot, and of three above the three succeeding pairs of feet; there is however but one above the posterior foot. (M. E.)

M. Milne Edwards divides this genus into the following sections:—

§ 1. Species whose front is entire and does not present lateral teeth.

a. Front triangular.

Example, *Porcellana violacea*. Length about an inch.

Locality.—The coasts of Chile.

N.B. The species belonging to this section appear to have a wide geographical range: some are recorded from New Zealand, New Ireland, Java, and the Isle of France, as well as Chile.

a, a. Front straight or slightly rounded.

Example, *Porcellana sculpta*. Colour reddish with great white spots. Length about three lines.

Locality.—The coasts of Java.

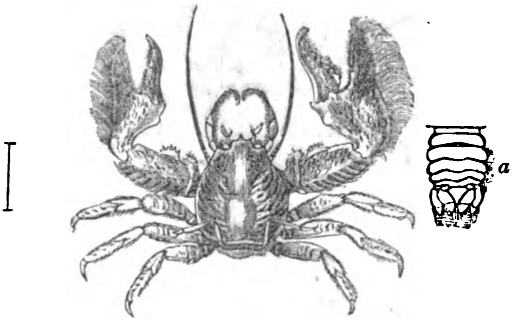
Two other species are recorded, one of them from the China seas: the other is *Porcellana viridis*, Gray, *Zool. Misc.*; *Pisidia viridis*, Leach.

§ 2. Species whose front is divided into three or five teeth or lobes.

b. Hands very wide and flattened. Pincers triangular.

Example, *Porcellana platycheles*. Length about 7 lines. Colour brownish.

Locality.—Coasts of England and France.



Porcellana platycheles. *a*, tail unfolded.

b, b. Hands long, narrow, and thick; pincers slender.

Example, *Porcellana longicornis* (*Pisidia longicornis*, Leach; *Cancer longicornis*, Penn., *Brit. Zool.*). Length about 3 lines.

Locality.—Coasts of England and France.

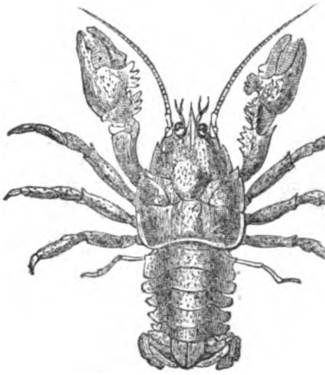
M. Milne Edwards thinks that the division of this genus into two, under the name of *Pisidia*, as well as *Porcellana*, by Dr. Leach, has been effected without sufficient reason. M. Desmarest, though he adopts it, shows that the former genus is established upon insufficient characters; therefore M. Milne Edwards thinks that it ought to be abandoned.

Æglea. Leach.

Generic Character.—*Carapace* depressed and much longer than it is wide, divided into two portions by a furrow which separates the stomachal from the cardial and branchial regions: these last are dilated, and terminated externally by a trenchant border. The *front* is armed with a rostrum, at the base of which is seen on each side a notch which represents the orbit. *Ocular peduncles* very short and directed forwards. *Internal antennæ* inserted below the ocular peduncles, and their very short stem bent back between those organs and the base of the rostrum; their basilar joint globular. *External antennæ* inserted on the same line as the internal ones, in the lateral angle of the carapace; their peduncle composed of four joints, the three first of which are extremely small, and the fourth cylindrical and more elongated. *Buccal* frame wider forwards than backwards, and not separated from the epistome. *External jaw-feet* pediform; their second and third joints scarcely larger than the three last, and exceeded by the palp. *Sternal plastron* triangular and very wide at its base, which is situated between the fourth pair of feet. Last segment of the thorax very moveable and fairly developed. Anterior *feet* of moderate length, but stout and convex, directed forwards and not outwards as in the *Porcellanæ*, and bent back below; the claw is strong and slightly hollowed out into a spoon-shape at the end. The three succeeding pairs of feet are slender and moderate; their tarsus styliform and rather elongated. Posterior feet slender, cylindrical, nearly filiform, terminated by a rudimentary claw, and bent back above the base of the others, or even in the branchial cavity. *Abdomen* shorter than the carapace, and habitually recurved below against the thorax, so tht it is impossible to straighten it completely; it is very wide, and furnished above with seven crustaceous segments, but completely membranous below. The fin which terminates it is very wide, but its median piece (formed by the seventh abdominal ring) is small, and does not form a fan with the lateral pieces, which are distant from it, and supported on a very long basilar joint. In the male, the first five rings of the abdomen are completely deprived of appendages; but in the female there are four pairs of false oviferous feet, which are simple, nearly membranous, and each terminated by a small oval blade. (M. E.)

M. Milne Edwards remarks that this genus, in his opinion, approaches the *Porcellanæ* more nearly than the *Galatheæ*, next to which they had been hitherto placed; but the conformation of the abdomen of the *Ægleæ* seems to him to indicate that their natural position is in the section of *Anomura*. [Galatheidæ.]

Example, *Æglea lævis*. Length about two inches.
Locality.—Coasts of Chile.



Æglea lævis.

Megalops, Leach.

M. Milne Edwards observes that the small crustaceans designated by this generic name has much analogy with the *Galatheidæ* as well as the *Porcellanidæ;* and if they be really animals arrived at their entire development, they would seem to establish the passage between the *Anomurous* and *Macrurous Decapods;* for their abdomen, though it does not present at its extremity five blades united into a fan-shape, as in the last, is very much developed, and serves for natation. But he is led to believe that they are only the young of some anomurous crustacean; and that when the form has been better studied, it will be erased from the list of genera which compose the order of *Decapods*, or, at least, will be assigned a different place and other characters. [Megalops.]

Monolepis, Say.

M. Milne Edwards is inclined to believe that this genus ought not to be retained, and that it has only been established on young crustaceans not arrived at their complete development; but not having himself observed them, he cannot form a decisive opinion on this point. They appear, he adds, to have the greatest analogy with *Megalops* and young *Dromiæ*. The reader is referred to Mr. Say's paper on the subject, in the 'Journal of the Academy of Philadelphia;' to Desmarest's work (*Consid. sur les Crust.*); and to the 'Histoire Naturelle des Crustacés' of M. Milne Edwards. The species recorded are both American.

PORCE'LLIO. [Isopoda, vol. xiii., p. 55.]

PORCH (from the Latin *porticus*), a general term for any projection forming a covered space immediately before the entrance to a building, open in front, and more or less enclosed at its sides. The distinction between a porch and a portico is, that, however important it may be as a feature, the former appears only a subordinate part of the building to which it is attached; whereas the other [Portico] may be the whole of a front: therefore, though the term porch is usually employed only in speaking of Lombardic, Norman, Gothic, and similar styles, it would be more correct and convenient to apply it, without regard to style, to what bears the character of a porch. By attending to such distinction, misconception would sometimes be prevented: for instance, if the Athenæum Club-house, London, were described as having a Doric portico, any one unacquainted with the design would imagine that the order was carried up as high as the general entablature of the building; whereas by terming it a Doric porch, such misconception would be avoided.

As far as we are aware, the only instance of a porch in Greek architecture is that in the octagonal structure called the Tower of the Winds, or that of Andronicus Cyrrhestes, which has a small prostyle portal on two of its faces, north-east and north-west, each consisting of a simple distyle, or two columns and their entablature, surmounted by a pediment; and which therefore may be regarded as the prototype of those ornamental compositions for doors and windows, so greatly affected in Italian architecture, which present a *microstyle* application of the orders, that is, small columns adapted not to the entire structure, but to subordinate parts of it.

When portico fronts were laid aside, as partaking too much of the previous Pagan temple; when columns began to be not only attached to the building, but employed as microstyle decorations to its different external stages or stories, often very irregularly, and generally connected together by arches; in short, when the Roman style was transformed into and superseded by the Byzantine—or what Mr. Wightwick terms the Constantinal—and the Lombardic styles, porches began to be important features, subordinate indeed in size to the structures to which they were attached, but principal in regard to embellishment, being frequently composed of groups of small columns, elaborately wrought, and some of them often placed on the backs of lions or other animals, and supporting a series of concentric arches or archivolt mouldings equally enriched. Here microstyle embellishment may be said to have been carried to such a height as to be ultimately lost sight of: the columns became at length mere subsidiary members, and a combination of vertical mouldings or shafts cut out of the receding angles constituted the general splay of the whole portal, which was thus extended in appearance ad libitum, without regard to the size of the actual doorway or aperture itself, a very important advantage as regards design. In the Norman-Gothic style, the porches or portals are little more than a modification of the similar features in Byzantine and Lombardic architecture. Of porches however strictly so called, that is, portals projecting out from the edifice, so as to form a sheltered external vestibule, we have few Norman instances, and those do not occur in the principal front, but at the sides of buildings. The same also is the case in Gothic architecture, where, though we often meet with spacious and magnificent portals, especially in continental examples, we do not find advanced porches brought out beyond the general plan of the building in front; the porch being there almost invariably enclosed within the lower part of the structure, even where it may be said to project with respect to that part of the front which is seen above it, but on a different plane, as for instance in the front of Westminster Hall, Winchester Cathedral, &c., although in those cases the entrances are placed rather within deep recesses than porches. In church architecture, entrances of the last-mentioned kind hardly ever occur at the west end or front, but were frequently made very conspicuous features in the side elevations, of which we have striking instances in the beautiful north porches at Salisbury and Wells cathedrals, both of which advance out very considerably.

In our antient domestic architecture, on the contrary, the porch, where it occurs at all, forms a marked, though not always a central feature, in the principal front. When it projects from the main structure, it is usually carried up so as to have a room, or else what forms a bay in a room, over it; and it is not unfrequently carried up higher than the rest, so as to form a kind of tower; or else the porch is recessed within the building, and presents externally merely an open arch. In many Elizabethan buildings, the porch, though forming a narrow compartment of the whole front, is profusely ornamented, even where the rest is quite plain. Kirby, in Northamptonshire, the seat of Lord-Chancellor Hatton, offers a most elaborate, not to say extravagant, example of the kind. In modern imitations of our older domestic architecture, it is now usually the practice to form the entrance porch in such manner that carriages can drive into it, by making an arch of sufficient width on each of its returns or sides. But as it is generally managed, the effect is seldom good, or indeed tolerable. Even that which forms the state entrance in the quadrangle at Windsor Castle is by no means unexceptionable.

PORCHESTER CASTLE. [Hampshire.]

PO'RCIA. [BRUTUS.]

PORCUPINES, *Hystricidæ*, a family of rodent quadrupeds.

The genus *Hystrix* of Linnæus embraces those *Rodents* whose covering consists, for the most part, of a kind of offensive and defensive armour, in the shape of spines or quills, instead of hairs.

Cuvier, who places the *Porcupines* between the genus *Myopotamus* [COYPOU] and the genus *Lepus*, observes that they are to be recognised at the first glance by the stiff and pointed spines with which they are armed, after the manner of the *Hedgehogs* among the *Carnassiers*. Their molars are, he proceeds to state, four in number, with a flattened crown, variously modified by layers of enamel, which leave deep intervals; their tongue is rough with spiny scales; their clavicles are too small to be applied to the sternum and omoplate, and are only suspended by ligaments. Many of them live in burrows, and have much the habits of Rabbits. Their grunting voice, joined to their large and truncated muzzle, has, he says in conclusion, caused them to be compared to the Hog, whence their French name *Porc-Epic*, and, he might have added, their English appellation.

He divides the group into, 1, the Porcupines properly so called (*Hystrix cristata*, Lin.); 2, *Atherura*, Cuv. (*Hystrix fasciculata*, Lin.); 3, *Les Ursons* (*Eréthisons*, F. Cuv.; *Hystrix dorsata*, Lin.); and, 4, *Les Coendous* (*Synætheres*, F. Cuv.; *Hystrix prehensilis*, Lin.; and *Hystrix insidiosa*, Licht.).

Mr. J. E. Gray makes the '*Histricidæ*' the second family of the order *Glires*, with the following character:—

Cutting teeth two in each jaw, lower truncated; grinders 4—4 in each jaw, rooted, compound; tongue and body covered with spines; clavicles none.

† Tail short.

1. '*Histrix*.' 2. *Acanthia*.

†† Tail elongated.

3. *Erythizon*. 4. '*Spygurus*.' 5. '*Simthurus*,' F. Cuv. (Synetheres ?).

This family is placed by Mr. Gray between the *Muridæ* and *Leporidæ*.

Mr. Bennett (*Zoological Gardens*) remarks that all the Porcupines have four cheek-teeth on each side of either jaw, furnished with distinct roots, nearly equal in size, irregular but somewhat circular in outline, presenting in the young state, on the surface of their crowns, several tubercles, of various size and form. He goes on to observe that, as the teeth are worn down, in advancing age, these tubercles give rise to as many elliptical layers of enamel occupying the centre of the tooth, while its circumference is marked, both internally and externally, by a folding inwards of the outer coat. He well describes their other leading features and peculiarities. 'Their tongues,' says he, 'are roughened by papillæ, like those of cats; their heads generally short and truncate; their nostrils large and open; their ears and eyes comparatively small; and their general form short, thick, and clumsy.'

With regard to the arrangement of this natural family, proposed by M. F. Cuvier, the same author observes that the French zoologist has attempted to subdivide it into smaller generic groups, dependent chiefly on his own theoretic notions of the value of the slightest modifications in the form of the skull and teeth in the discrimination of genera. Some variations in the number of toes, and still more remarkable peculiarities in the structure of the tail, are brought in aid of this subdivision; but Mr. Bennett remarks that he can scarcely admit the justice of M. F. Cuvier's views, unless when supported by a marked difference in the mode of life, such as exists between the burrowing porcupines of the old continent, the arboreal species of North America, and the prehensile-tailed climbers of the south. Mr. Bennett, however, though not without some hesitation, adopts the views of M. F. Cuvier with regard to *Atherura*, which he considers as furnishing the type of a new genus, to which he would add, as a second species, the *Landak* of Marsden's 'History of Sumatra.'

Mr. Swainson expresses a suspicion that the genus *Hystrix* is one of the most typical in the order *Rodentia*, and he observes that M. F. Cuvier appears moreover to have distinguished the five types of forms which Mr. Swainson thinks every natural group is sure to contain.

The typical or *Common Porcupine* has, says Mr. Swainson in continuation, the spines of very great length, but the tail is very short.

The next type is M. F. Cuvier's subgenus *Erethizon*, in which, Mr. Swainson observes, the proportions of the European species are, as it were, completely reversed. The hair of the body, which in *Hystrix* is much shorter than the spines, in this type is considerably longer; while the spines themselves are so short that at a distance they are scarcely seen. The tail also is nearly half as long as the body.

The third subgenus, he remarks, has the tail, which is short in *Hystrix*, and moderate in *Erethizon*, of considerable length, and it is further distinguished by being prehensile. 'A more important circumstance,' continues Mr. Swainson, 'for considering this animal as the type of a subgenus could not possibly be named. One half of the tail is covered with spines, and the other with scales. There is no doubt that M. F. Cuvier is perfectly right in supposing that the species described by Azara is different from that mentioned by Buffon. We ourselves in fact, although unable to transport the skins, have seen two very different kinds of these prehensile-tailed porcupines in the forests of Brazil; and no doubt others exist in that vast continent. This fact however is sufficient to show that M. F. Cuvier, one of those "amateurs of generic divisions," as he is spoken of by a modern compiler, has founded this genus upon the most solid principles. The Indian porcupines constitute the subgenus *Acanthion*, and they differ very remarkably from all the preceding; the spines are no longer round, but assume the flattened appearance of strips of parchment; indeed M. Cuvier remarks that in one species, the *Hystrix fasiculata* of Linnæus, the spines of the body are flattened like a sword-blade; the tail is long and terminated by a bundle of spines, "flattened like strips of parchment." There must be something very different in the habits of these Indian porcupines from those of America and Europe; nor would an ordinary observer class them in the same genus; for we even find that Desmarest, one of the best zoologists of France, considers the animal in question as belonging to the genus *Mus*, or in other words, a species of spined rat. Thus much for the distinctions of the subgenus *Acanthion*, of which three species have already been discovered.'

The last subgeneric group noticed by Mr. Swainson is *Sphigurus*, and, in further proof that M. F. Cuvier has unconsciously marked out the circular arrangement, and defined the natural subgenera of the genus *Hystrix*, Mr. Swainson remarks that the two most typical, *Hystrix* and *Acanthion*, agree in their teeth, while the three aberrant types, namely, *Erethizon*, *Synætheres*, and *Sphigurus*, possess certain modifications, constant among themselves, but sufficiently distinct from the former.

In the arrangement at the end of the volume (*Classification of Quadrupeds*) from which we have quoted, the genus *Hystrix* stands at the head of the second division of the Glires (*clavicles rudimentary or none*), and Mr. Swainson adopts the following subgenera, established by M. F. Cuvier, but rejects *Atherura*, as being only an aberrant species:—*Acanthion*, *Erethizon*, *Synætheres*, and *Sphigurus*. The genus *Hystrix* is followed by that of *Lepus*.

Mr. Waterhouse, in his tabular view of the distribution o the *Rodentia*, laid before the Zoological Society of London, in November, 1839, makes the subfamily *Hystricina* consist of the *Hystricidæ*, the *Octodontidæ*, the *Chinchillidæ*, and the *Caviidæ*. To Europe and North Asia he gives one species of *Hystricidæ* (*Hystrix*). To North America one (*Erethizon*). To Africa one (*Hystrix*). To India and the Indian Islands two, viz. one *Hystrix* and one *Atherura*. To South America and the West Indian Islands he gives five, viz. three of *Cercolabes* and two of *Synætheres*.

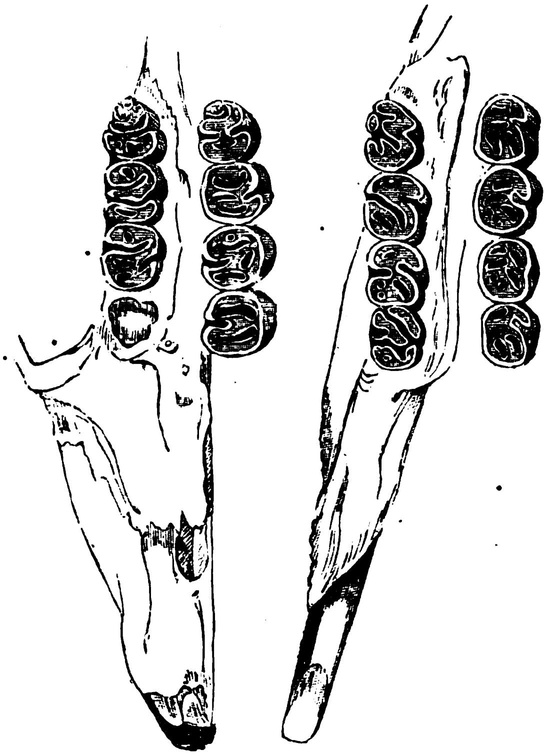
We proceed to lay some of these forms before our readers.

Hystrix, Linn.

This genus is distinguished by the head being more or less convex, and by the development of the bones of the nose, which are very much extended; temporal and orbital fossæ very small; parietal bones depressed, occipital and sagittal crests projecting very much, tail short, not prehensile, feet plantigrade, the anterior tetradactyle, the posterior pentadactyle, armed with large nails.

M. F. Cuvier gives to the Porcupines (*Hystrix* and the *Acanthions*) the following—

Dental Formula:—Incisors $\frac{2}{2}$; molars $\frac{4-4}{4-4} = 20$.



Teeth of Hystrix (F. Cuv.).

Example, *Hystrix cristata*, the *Italian* or *African Porcupine*, or *Common Porcupine*.

Description.—When full grown about two feet in length; longest spines exceeding a foot. General colour grizzled dusky black, resulting from an intermixture of various shades of white, brown, and black. Upper part of the head and neck furnished with a crest of long lighter-coloured hairs capable of being raised or depressed at pleasure. Hair on the muzzle and limbs very short, almost black on the limbs; that of the neck and under parts brownish, and of considerable length. On the fore-part and sides of the neck a whitish band; all the remaining parts of the back and sides, including the rump and upper parts of the hinder legs, armed with spines, which are longest on the centre of the back. The spines almost of the thickness of a goose-quill in the middle, supported at the base by a slender pedicle, and terminating in very sharp points, striated longitudinally and ringed alternately with black and white; the rings an inch or more broad. Their usual position is lying nearly flat upon the body with the points directed backwards; when the animal is excited they are raised by the means of the subcutaneous muscles, almost at right angles with the body, and then present a very formidable appearance. They are not capable of being detached at the pleasure of the animal. The tail-quills are, as it were, cut off in the middle, and consequently open at the ends, and produce a loud rustling noise when the animal agitates its tail. (Bennett.)

Hystrix cristata.

This is the ὕστριξ (Hystrix) of Aristotle and the Greeks, and according to Agricola, the ἀκανθοχοιρος (Acanthochœrus) of the latter; *Hystrix* of the antient Italians; *Istrice* of the modern Italians; *Porcépic* of the French; *Stachelschwein*, *Dornschwein*, and *Porcopick* of the Germans.

Habits, Food, &c.—The Porcupine is a nocturnal animal, sleeping in its burrow during the day, and coming forth at nightfall to seek its food, consisting principally of roots, fruits, and tender leaves. Thunberg states that its usual food near the Cape, where it is called *Yzer-varken*, is the root of that beautiful plant the *Calla Æthiopica*, which grew even in the ditches about the gardens; but he adds that it will frequently deign to put up with cabbages and other vegetables, and sometimes commits great depredations in those gardens. The story of its power of shooting its quills to a distance at its enemy is merely glanced at by Aristotle (*Hist. Anim.*, ix. 39), but dwelt upon by Pliny with his usual love for the marvellous. (*Hist. Nat.*, viii. 35.) Ælian, Oppian, and Claudian have repeated this tale with exaggerations. In suddenly raising his spiny armour, a loose quill may be detached by the porcupine; but the power of ejaculation to a distance does not exist. There are usually several openings to the porcupine's burrow, and it hybernates, but only for a short time. Mr. Bennett quotes Thunberg, not without observation on his credulity, for the use which he was told the Ceylonese Porcupine makes of the tail-quills. Thunberg was informed that it had 'a very curious method of fetching water for its young, viz. the quills in the tail are said to be hollow, and to have a hole at the extremity; and that the animal can bend them in such a manner as that they can be filled with water, which afterwards is discharged in the nest among the young.' Pennant says, 'These animals produce a bezoar; but according to Seba, only those which inhabit Java, Sumatra, and Malacca. These bezoars were very highly valued, and have been sold for five hundred crowns a piece. It has also been pretended that a stone was procured from the head of this animal infinitely more efficacious than other bezoars (Tavernier); but this may be placed among the many impositions of Oriental empirics.' In September, 1833, the secretary of the Zoological Society called attention to a young *Hystrix cristata* which had been recently brought forth in the menagerie, being the first instance of such an occurrence in this species, and respecting which he added that observation of the young while sucking confirmed the correctness of Blumenbach's statement that the nipple is nearly axillary.

Geographical Distribution.—'Hystrices,' says Pliny (*loc. cit.*) generat India et Africa.' Agricola, in his book, *De Animantibus subterraneis*, remarks, 'Hoc animal gignit India et Africa, unde ad nos nuper allatum est.' Pennant states that it inhabits India, the sand-hills on the south-west of the Caspian Sea, Southern Tartary, Persia, Palestine, and all parts of Africa. He adds that it is found wild in Italy, and is brought into the markets of Rome, where it is eaten, but that it is not originally a native of Europe (for this last he quotes Agricola). The specimens from Italy are generally rather smaller, and have shorter quills. See further the quotation from Mr. Waterhouse's tabular view cited above.

Lieut.-Col. Sykes has described a species under the name of *Hystrix leucurus*, *Sayal* of the Mahrattas, as *Hystrix caudâ albâ*. He states that the animal appears to be distinct from the European species, which it closely resembles in form and covering. It is nearly a third larger. All the spines and open tubes of the tail are entirely white, which is not the case in *Hystrix cristata*. The spines of the crest also are so long as to reach the insertion of the tail. The ears are much less rounded, and the nails are shorter, infinitely deeper and more compressed, and with deep channels below. The white gular band is more marked; and, finally, the Asiatic species is totally destitute of hair—spines, where wanting, being replaced by strong bristles even down to the nails. (*Zool. Proc.*, 1830, 1831.) Mr. Hodgson notes this species among the mammalia of Nepaul, as inhabiting the central and lower regions. (*Zool. Proc.*, 1834.)

Atherura, Cuv. (*Acanthion?* F. Cuv.)

Neither the head nor the muzzle convex; tail long but not prehensile; feet like those of *Hystrix*.

Example, *Atherura cristata, Hystrix fasciculata*, Shaw; *Le Porcépic à queue en pinceau*, Buff.

Cuvier describes this species as having the spines of the body hollowed into a furrow forwards, and having the tail terminated by a fasciculus of horny flattened strips (lanières cornées aplaties) constricted at intervals (etranglées d'espace en espace).

Mr. Bennett (*Gardens and Menagerie of the Zoological Society*) remarks that although tolerably described and figured by Buffon, this species had been lost to science until within two years from the time he wrote (1830), when it was recovered almost simultaneously both in its original habitat and in a very distant quarter of the globe. Sir Stamford Raffles, he observes, had cursorily referred to it, and he presumes that the authority on which it was formed into a new genus by Cuvier was a skeleton and skin transmitted from India by M. Diard in the year 1828. Nearly at the same time, he tells us, a living individual was brought to England and presented to the Zoological Society by Lieutenant Vidal, who accompanied the expedition for the formation of the projected colony at Fernando Po, where these animals were found in such plenty as to afford a staple article of food to the inhabitants. It has been conjectured, he adds, on very probable grounds, that they are not indigenous in the island, but had been brought thither from the East by the Portuguese, who were formerly settled there; but he observes that the space interposed between the two regions can scarcely be regarded as conclusive evidence of their having been introduced into the colony, while there are such striking instances of animals common to India and the west of Africa as are furnished by the lion, the leopard, &c.

Mr. Bennett proceeds to state that in the teeth and in the organs of motion it corresponds, as Baron Cuvier has noticed, with the common Porcupine, from which it differs chiefly in the form of the head; the line of its profile, instead of being elevated into a curve of large extent, passing in almost a straight direction from the occiput to the extremity of the nose. In these respects, Mr. Bennett remarks in continuation, it agrees with M. F. Cuvier's genus *Acanthion*, founded on this very character observed by the latter on two skulls preserved in the Paris museum, the one from Java, the other, in all probability, from Africa. These coincidences would have induced Mr. Bennett to consider the two genera as identical, were it not that Baron Cuvier has omitted all mention of that established by his brother, although the materials for comparison were fully at his disposal: M. F. Cuvier moreover enumerates them both in his genera of *Mammalia*.

Mr. Bennett further observes that Linnæus founded his *Hystrix Macroura* on Seba's figure; but Buffon having quoted neither Seba nor Linnæus, Dr. Shaw took it for granted that this was a different animal, and consequently gave it a new name—*Hystrix fasciculata*. Mr. Bennett entertained however but little doubt, notwithstanding some trifling discrepancies in the figures, that Sir Stamford Raffles was right in his conjecture that they both represent one and the same species.

The following is Mr. Bennett's accurate description:—'The differences between this species and the common Porcupine are obvious at the first glance. Its general colour is nearly the same, but with less intermixture of brown. The upper parts of the body, the outer sides of the limbs, and the head, neck, and face, are of this dusky hue; but the under parts, inside of the limbs, fore part of the neck, and throat, are of a greyish white, with the exception of a darker band which crosses the breast in front of the fore legs. The spines commence upon the back of the head, where they are little more than an inch in length, and extend to the root of the tail, occupying nearly the whole of the back and sides. The longest are scarcely more than from four to five inches in length, and extend to the root of the tail, occupying nearly the whole of the back and sides. They are mostly white at the base and black towards the extremity, but many of them are black throughout, and others black above and white beneath. All of them are marked on the upper surface by a deep and broad groove running the whole of their length, and terminate in very sharp points. The skin in which they are implanted appears perfectly white, and where the spines are most numerous, is scarcely furnished with a single hair. A few slenderer spines running into long black bristles are occasionally intermixed with the others. The greater part of the tail is bare both of hairs and spines, and covered only by flat blackish scales disposed in rings, the tip alone being surmounted by a tuft of long flat bristles having the form neither of hairs nor of quills, but bearing a close resemblance, as Buffon has aptly remarked, to narrow slips of parchment cut in an irregular manner. This tuft is of a whitish colour, and about two inches in length. The entire length of the body in our specimen is little more than a foot, and that of the tail from four to five inches. The whiskers are very long; the eyes small and black; and the ears short, round, and naked.'

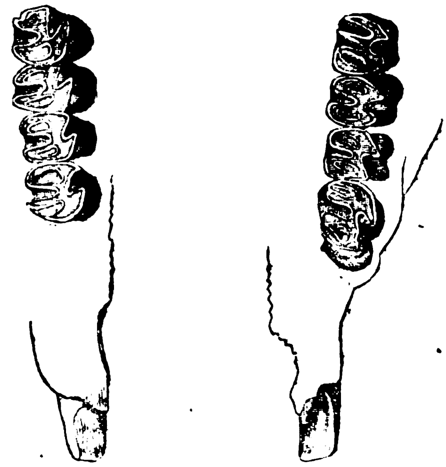
Habits, Food, &c.—The author last quoted states that, like the rest of its tribe, this species sleeps during the day, and becomes in some degree active only on the approach of night. Its intelligence, he adds, is equally limited, and its manners equally fretful with those of the common species, like which, 'it raises its spines when irritated or disturbed, stamps with its feet upon the floor of its cage, and swells and looks big in its defensive armour.'

Geographical Distribution.—The neighbourhood of the Celebes (Seba); Asia (Linn.); Malay Peninsula (Buffon); Isles of the Indian Archipelago (Pennant); Sumatra (Sir Stamford Raffles); Fernando Po (Vidal).

Erethizon. (F. Cuv.)

Cranium flat; muzzle short and not convex; tail moderate; quills short and half hidden in the hair.

The following is from M. F. Cuvier's figure of the teeth of *Erethizon*, *Synœtheres*, and *Sphigurus*.



Teeth of Erethizon, &c. (F. Cuv.)

Example, *Erethizon dorsatum, Hystrix dorsata*, Linn.

Description.—Ears short, hid in the fur; head, body, legs, and upper part of the tail covered with soft, long, dark-brown hair; on the upper part of the head, back, body, and tail, numbers of sharp strong quills, the longest on the back, the least towards the head and sides, the longest three inches, but all hid in the hair; intermixed are some stiff straggling hairs, three inches longer than the rest, tipped with dirty white; under side of the tail white; four toes on the fore feet, five behind, each armed with long claws, hollowed on their under side; the form of the body is exactly that of a beaver, but is not half the size; one which Mr. Banks brought from Newfoundland was about the size of a hare, but more compactly made; the tail about six inches long. (Pennant.)

These animals vary in intensity of colour. Pennant alludes to one entirely white in the possession of Sir Ashton Lever.

This is the *Cavia Hudsonis* of Klein; *Hystrix Hudsonius* of Brisson; *Hystrix pilosus* of Catesby; *Hystrix dorsata* of Linnæus; *L'Urson* of Buffon; *Canada Porcupine* of Forster, Pennant, and others; *Cawquaw* of the Cree Indians; and *Ooketook* of the Esquimaux.

Habits; Food; Geographical Distribution.—The *Canada Porcupine* is a sluggish animal. Hearne says that the Indians going with packets from fort to fort, often see them in the trees, but not having occasion for them at the time, leave them till their return, and should their absence be a week or ten days, they are sure to find the porcupines within a mile of the place where they had before seen them. Mr. Hutchins states that, in walking, the tail is drawn along the snow, making a deep track, which is often the means of betraying the animal; but that its haunts are most readily discovered by the barked trees on which it has fed, which, if barked the same winter, are sure signs of their vicinity. They are, he says, usually found on the branches, and, on approaching them, they make a crying noise like a child. Then the tree is cut down, and the animal killed by a blow on the nose. Dr. Richardson informs us that this species is found on the banks of the Mackenzie, as high as lat. 67°, and that, according to American writers, it ranges as far south as lat. 37°. He adds, that it is said to be very rare in Virginia, but to be numerous in some parts of Kentucky; and that it is reported to have multiplied greatly, of late years, near Oneida Lake in the state of New York. (Cozzens.) Dr. Richardson further states that in the fur countries it is most numerous in sandy districts covered with the *Pinus Banksiana*, on the bark of which it delights to feed; that it also eats the bark of the larch and spruce firs, and the buds of various kinds of willow; and that, in the more southern districts, it is said to feed chiefly on the bark and leaves of the *Pinus Canadensis* and *Tilia glabra*, and to be fond of sweet apples and young maize, which it eats in a sitting posture, holding the food to its mouth with the fore-paws. 'It is,' continues the Doctor, 'readily attacked by the Indian dogs, and soon killed, but not without injury to its assailants, for its quills, which it erects when attacked, are rough, with minute teeth directed backwards, that have the effect of rendering this seemingly weak and flexible weapon a very dangerous one. Their points, which are pretty sharp, have no sooner insinuated themselves into the skin of an assailant, than they gradually bury themselves, and travel onwards until they cause death by wounding some vital organ. These spines, which are detached from the porcupine by the slightest touch, and probably by the will of the animal, soon fill the mouths of the dogs which worry it, and unless the Indian women carefully pick them out, seldom fail to kill them. Wolves occasionally die from the same cause. The Canada Porcupine makes its retreat amongst the roots of an old tree, and is said to pass much of its time in sleeping. When disturbed, it makes a whining or mewing noise. It pairs in the latter end of September, and brings forth two young ones in April or May. Its flesh, which tastes like flabby pork, is relished by the Indians, but is soon nauseated by Europeans. The bones are often deeply tinged with a greenish-yellow colour. Like other animals which feed on coarse vegetable substances, it is much infested by intestinal worms. The quills or spines are dyed of various bright colours by the native women, and worked into shot-pouches, belts, shoes, and other ornamental articles of dress.' (*Fauna Boreali-Americana.*)

Synætheres. (F. Cuv.)

Muzzle large and short; head convex in front; spines short; tail very long, naked at the end, and prehensile, like that of an opossum (Sarigue) or of a Sapajou; feet with only four toes, armed with claws.

Example, *Synætheres prehensilis; Hystrix prehensilis*, Linn.

Description.—Nose short and blunt; long white whiskers; beneath the nose a bed of small spines; top of the head, back, sides, and base of the tail covered with spines; the longest on the lower part of the back and tail, three inches in length, very sharp, white, barred near their points with black; adhere closely to the skin, which is quite naked between them; are shorter and weaker as they approach the belly; on the breast, belly, and lower part of the legs are converted into dark brown bristles; feet divided into four toes; claws very long; on the place of the thumb a great protuberance; tail eighteen inches long, slender, and taper towards the end; the last ten inches almost naked, having only a few hairs on it; has, for that length, a strong prehensile quality. (Pennant).

This appears to be the *Cuandu* (major) of Marcgrave and Piso; *Orico Cachero* and *Espinho* of the Portuguese; *Hoitzlacuatzin?* of Hernandez; the *Brazilian Porcupine* of authors.

Habits, Food, Geographical Distribution, &c.—The *Brazilian Porcupine* appears very much to resemble the *Canada Porcupine* in its habits, living in woods, sleeping by day, and feeding on fruits, &c. by night. Marcgrave states that its voice is like that of a sow. The quills are stated to have the same penetrating and destructive quality as those of the Canadian species. It is a sluggish animal, climbing trees very slowly, and holding on with its prehensile tail, especially in its descent. It grows very fat, and the flesh is said to be white and well-tasted. Our cut is taken from a living specimen in the garden of the Zoological Society, Regent's Park.

Synætheres prehensilis.

The genus *Sphigurus* appears to be founded on the *Coui* of Azara.

FOSSIL HYSTRICIDÆ.

Cuvier (*Ossemens Fossiles*, vol. v., part 2, p. 518) states that Mr. Pentland found in the Val d' Arno, near San Giovanni, in the same sandy beds which contain so many bones of large quadrupeds, a molar tooth exactly resembling that of a great porcupine, but which appeared to be fossil.

PORDENO'NE. GIOVANNI ANTO'NIO LICI'NIO, or LICINO, called *Il Pordenone*, was born at Pordenone in Friuli, in the year 1484. From the vigour of conception, the elevation of mind, and the style of execution which distinguish his works, it has been presumed, though it is not certain, that he frequented the school of Giorgione. Though on the whole inferior to Titian, he was his rival, and not always without success. He was an able colourist in oil, but chiefly excelled in fresco. As he principally painted frescoes in North or Upper Italy, he was known in Lower Italy only by his fine oil paintings. His most splendid work in oil is the altarpiece of Santa Maria dell' Orto, at Venice, representing a S. Lorenzo Giustiniani, surrounded by other saints, among whom are St. John the Baptist and St. Augustin. The frescoes of Pordenone are spread over the towns and castles of Friuli; some are at Genoa, Mantua, and Venice, but the best preserved are at Piacenza and Cremona. He was highly esteemed by the emperor Charles V., who ennobled him. Hercules II., duke of Mantua, called him to Mantua to paint cartoons for tapestry to be made in Flanders, but he soon afterwards died (in 1540), as it was suspected, of poison. It must be observed that he adopted the name of *Regillo.*

There are some of Pordenone's pictures in England:—at Hampton Court, a large rich picture of himself and family, and two other pictures; three in the collection of the late Sir Abraham Hume; in the Stafford collection, the Woman taken in Adultery, figures the size of life; at Corsham House a large picture of the Virgin and Child and St. Peter, ascribed to Titian, but which Dr. Waagen thinks to be by Pordenone; at Alton House (the earl of Shrewsbury's) a fine picture of the Death of Peter Martyr; at Burleigh House (the Marquis of Exeter's), 1, the Finding of Moses; 2, the Adoration of the Magi; the figures in both are whole length, the size of life. Dr. Waagen bestows high commendation on both pictures (the latter is erroneously ascribed to Bassano), and observes that he knows no other gallery that can boast of two such works of this master, whose pictures are so rare.

PORE. [SKIN.]

PORISM (πόρισμα). An intermediate class of propositions, between problems and theorems, was, as we are informed by Pappus, distinguished by the antient geometers under the name of porisms. Unfortunately however the only notices of them by the antients themselves, which are found in their remaining works, occur in the 'Collectiones Mathematicæ' of Pappus Alexandrinus, and the commentaries of Proclus on the Elements of Euclid, in both places so very imperfectly, that till of late years mathematicians were not agreed on their exact interpretation. The description of porisms by Pappus, which he gives in the preface to the seventh book of his above-mentioned work, in an account of Euclid's work on the subject, is, in all the manuscripts which have been examined, extremely mutilated, and every attempt to restore them, before the masterly hand of Robert Simson took up the subject, had completely failed. The first part of the description, which seems to be entire, is calculated only to excite curiosity, being too general for conveying any precise notion of these propositions, or for giving any effectual assistance for the recovery of them; and the remainder, containing a detail of the contents of Euclid's work, is through the whole so corrupt that all endeavours to explain it were nugatory. Several celebrated geometers indeed flattered themselves that they had obtained possession of the secret; but even Dr. Halley, with all his acuteness, relinquished the task, and adds, after giving the original, 'hactenus porismatum descriptio nec mihi intellecta nec lectori profutura.' The definition which Pappus quotes from the antients is too general to be useful, and perhaps implied more than our acquaintance with the language in which he wrote can enable us to determine. He says that a 'theorem is something requiring demonstration, a problem in which something is proposed to be constructed; but a porism, that which requires investigation;' and though this definition certainly does correspond to the nature of these propositions, yet it is deficient in discrimination, and of itself neither conveys any precise notion of Euclid's porisms, nor gives assistance in the investigation of any individual proposition. Dr. Simson's restored definition is as follows, literally translated:—'A porism is a proposition in which it is proposed to demonstrate that some one thing or more things are given, to which, as also to each of innumerable other things not given, but which have the same relation to those which are given, it is to be shown that there belongs some common affection described in the proposition.' The following less literal translation may probably be better understood:—'A porism is a proposition in which it is proposed to demonstrate that one or more things are given, between which and every one of innumerable other things not given, *but assumed according to a given law*, a certain relation described in the proposition is to be shown to take place.' Dr. Simson illustrates the propriety and accuracy of this definition by many examples, and it is so framed as to correspond with all the intimations of Pappus respecting porisms, and also with the character of the few individual porisms of Euclid which Dr. Simson had discovered. It may therefore justly be considered as expressive of the notions on this subject entertained by the antients, although probably, as in the cases of theorem and problem, no precise definition was given of porism. It has been objected to Simson's definition, that it may be inferred from it that a porism partakes more of the nature of a problem than a theorem, and consequently is inconsistent with the 'intermediate nature' mentioned by Pappus. In his enunciation it is affirmed that certain things *may* be found which shall have the relations or properties therein described. Now were it simply proposed to investigate certain things which would have the properties expressed in the porism, it may be regarded as a problem; but if these things are found by a construction described in the enunciation, the proposition becomes a theorem affirming the truth of the properties asserted; and then a demonstration only is required, without any investigation, in the manner which appears to have been practised by the later mathematicians alluded to by Pappus. The enunciation of a porism as a problem is not consistent with the usual character of such propositions. Problems usually, whatever difficulty may attend their solution, are almost immediately recognised, by those having some knowledge of geometry, as either possible in certain circumstances of the data, or as altogether impossible; and it would be unusual to propose as a problem 'to find things with certain properties, respecting the possibility of which no judgment can be formed without an analysis, or such consideration as is equivalent to an analysis.' For example, if it had been proposed as a problem in the time of Apollonius, to find in a given parabola a point having the property of the focus, that point being then unknown, such a proposition would not have been considered as a proper problem, but would in reality have been a porism. To take another example:—Proclus, in his wretched commentaries on the Elements, mentions the first proposition of the third book, 'to find the centre of a circle, as a porism, being in some measure between a problem and a theorem. But Proclus, however distinguished as a philosopher, was no mathematician, and as a circle, from Euclid's definition of it, must have a centre, the proposition to find that centre seems to be a proper problem. Had the circle been defined from another of its properties, as, for instance, from its being produced by the extremity of a straight line moving at right angles to another straight line, given in magnitude and position, and in the same plane, so that the square of the moving line be always equal to the rectangle by the segments into which it divides the given line; then the finding of the centre would be a proper porism, and might be enunciated thus:—'within a given circle (defined in the manner just mentioned) a point may be found from which all straight lines drawn to the circumference will be equal.'

Having thus placed before our readers the most probable restoration of the antient meaning of the term porism, we proceed to notice briefly what modern geometers have given us on the subject. First in importance stands the admirable paper on porisms by Professor Playfair, in the first volume of the 'Transactions of the Royal Society of Edinburgh,' which was read before that body, in July, 1784. He improves on Simson's definition, and substitutes the following:—'A porism is a proposition affirming the possibility of finding such conditions as will render a certain problem indeterminate, or capable of innumerable solutions.' This, it must be confessed, is an important and elegant simplification, and fully conveys every idea contained in the more prolix definition of Simson; but at the same time we agree with Dr. Trail in thinking that Dr. Simson's is expressed more nearly in the language and manner of the antient geometers:—'Though I admire the ingenuity and fully admit the soundness of this definition, and also the utility of the principle on which it is founded in the discovery of porisms, I must acknowledge my doubt of that particular notion of a porism having ever been adopted, or even proposed, among the antient geometricians.' (Trail's *Life of Simson*, p. 50, 51.) A paper on porisms, containing some examples in the higher geometry, by the present Lord Brougham, was inserted in the 'Philosophical Transactions of the Royal Society,' in 1795. Fryer has given a popular history of the discovery of porisms, in the last edition of Simson's Geometry. Lastly, the most complete exposition of them that has yet appeared may be found in the *Aperçu Historique sur l'Origine et le Développement des Méthodes en Géométrie*, 4to., Brus., 1837, by M. Chasles of Chartres, a member of the French Institute, and one of the most distinguished geometers in Europe.

Porism was also used by the Greek geometers to denote a corollary to a proposition, and the frequent use of the word in this sense, as well as in the other, by Pappus and Proclus, has occasioned much confusion. Proclus says that 'corollary is one of the geometrical appellations, but it has a twofold signification,' and he proceeds to describe, in a very obscure manner, the difference between the two meanings of the term.

See *Proclus in Euclidem*, edit. Hervagii, fol. Basil., 1533, fol. 18. We refer the reader also to Henry Savile's *Prælectiones in Euclidem*, 4to. Oxon., 1621, p. 18; and Trail's *Life of Simson*, p. 92.

PORITES. [MADREPORÆA.]

PORO'DRAGUS, De Montfort's name for a genus of Belemnites, arranged by M. de Blainville in the section characterised by a swollen apex, and being straightened near the base.

PORPHY'RIO. [RALLIDÆ.]

PO'RPHYRY was born A.D. 233, either at Tyre, whence he is called Tyrius, or at Batanæa (Basan), a town of Syria, whence he is called Bataneotes. His original name was Melech, the Hebrew and Syriac for king, a circumstance which occasioned Suidas to say that his real name was Basileus. His preceptor Longinus changed his Syriac name into Porphyrius (a man 'in purple,' the adornment of a king). While he was yet a boy, he repaired to Origen, the famous Christian writer, who was then probably living at Cæsarea in Palestine, certainly not at his native city

Alexandria, as Holstenius represents, following Vincent of Lerins. Whether Porphyry became the pupil of Origen, or how long he continued with him, is uncertain. He afterwards went to Athens, where for some time he studied under Longinus, the celebrated philosopher and critic. We find him next at Rome, where in the thirtieth year of his age he was a scholar of Plotinus, whose Life he has written, and in it he has stated some particulars concerning himself. After a few years he went to Lilybæum in Sicily, and dwelt there till after the death of Plotinus, A.D. 270, whence he is sometimes called Siculus. Here, according to Eusebius and Jerome, he composed his fifteen books against the Christians; which books, with more zeal than wisdom, were about a century afterwards ordered to be publicly burnt by the emperor Theodosius the Elder. Porphyry died at Rome, towards the end of Diocletian's reign, about A.D. 304.

Porphyry has been usually called 'the philosopher.' He distinguished himself as an acute and learned man, and wrote in the Greek language upon a great variety of subjects, in a simple and graceful style. It is to be lamented that he employed his talents in opposing Christianity; but it was mistaken policy to destroy any of his writings. Christians of modern times would have been able to turn the arguments of Porphyry to good account in further establishing the truth of their religion. Fabricius has given a list of Porphyry's works amounting to sixty-one, divided into three classes, published, unpublished, and lost: the last class consists of forty-three distinct performances. A neat edition of his 'Life of Pythagoras' and three other works was published at Cambridge in 1655, with the Dissertation of Holstenius on the life and writings of Porphyry subjoined. Others of his works have been printed at different times; but no complete edition of all that are extant has yet appeared. The four books 'On Abstinence from Animal Food' (*περὶ ἀποχῆς τῶν ἐμψύχων*) are one of Porphyry's best works, and contain a great deal of curious matter applicable to illustrate the history of philosophy. His 'Introduction to the Categories of Aristotle,' which is a useful little treatise, is prefixed to the editions of the 'Organon.' He wrote also a 'Commentary on the Categories of Aristotle' in question and answer, which was edited by Bogard, 1543, 4to. The Commentary of Porphyry on the 'Harmonica' of Ptolemy is printed in the collection of Wallis: unfortunately, only the first book and the first seven chapters of the second are extant.

One of the works of Porphyry, and a fragment of another enumerated among the lost, were discovered by Mai, in the Ambrosian Library at Milan, and published by him in 1816. The former is styled 'Ad Marcellam.' It seems that Porphyry had married Marcella, the widow of a friend who was a Christian, and that at the end of ten months, upon taking a journey, he addressed this little work to her. The fragment, which is in verse, belongs to a work in ten books, known by the name of 'De Philosophia ex Oraculis Libri.'

(Suidas, *Lexicon*; Holstenius, *De Vitâ et Scriptis Porphyrii Dissertatio*; Fabricius, *Bibl. Græca*; *British Critic*, vol. v., 1829.)

PORPHYRY. A large number of rocks of igneous origin, both very antient and comparatively modern, are thus designated, yet this use of the term is neither accurate nor convenient. Properly speaking, a particular structure is indicated by it, and not a definite rock or family of rocks.

Felspar of a granular texture, without crystals imbedded, is claystone; with imbedded crystals of felspar it is porphyry; hornblende mixed with uncrystallized felspar makes some greenstones; with imbedded crystals of felspar this becomes greenstone-porphyry. Hence, by this mode of designation, we have pitchstone-porphyry, greenstone-porphyry, basaltic-porphyry, felspar-porphyry, and even so vague a term as trap-porphyry; and, on the other hand, more correctly, porphyritic pitchstone, porphyritic claystone, porphyritic greenstone, porphyritic basalt, and porphyritic granite.

Among volcanic rocks porphyritic trachytes are common.

Fine examples of porphyry (crystals of felspar in a base of uncrystallized felspar) occur in Scotland at Inverara and in Ben Nevis, in Cumberland on Armboth Fell, and in Cornwall, commonly under the title of Eurite.

PORRI'GO, *Ringworm,* is a pustular and contagious disease of the scalp, or, in some rare cases, of other parts where there is much hair. M. Biett describes two varieties of it under the names of P. favosa and P. scutulata. Dr. Willan described many more varieties, but he included in this name other widely different diseases.

Porrigo favosa consists of an eruption of small flat yellow pustules, with depressions at their centres, distinct or clustered, and which soon concrete into bright yellow honey-coloured scabs, on the surface of which the depressions of the centres of each pustule are usually still visible. After some time the scabs become thick and white; and drying, split and break off. Sometimes however they remain long adherent, the skin beneath them ulcerating, and the discharge oozing through them. The hair of the parts affected is always much loosened, and often falls off spontaneously; and, when it grows again, is weaker and lighter in colour than before.

Porrigo favosa appears rarely in any part except the scalp. It affects persons of all ages; but especially children from six to ten years old, and those who are naturally unhealthy, or ill-fed and dirty. It is distinctly communicable by contagion, and by this means may affect alike the weak and the robust.

It is one of the most obstinate diseases of the skin, and often lasts for months or years. The first measure for its cure is to cleanse the head completely with poultices or soap and water, and to have the hair cut very close. The dead hair and scabs must then be cleaned off as fast as they form. The medicines that promise the speediest success are lotions with sulphuret of potash or slightly acidulated, or with alkalis or their carbonates, such as in the following forms:—ten grains of potassa fusa in an ounce of water, to be applied occasionally; one or two drachms of subcarbonate of potash in a pint of water, to be constantly applied on linen; or from one to three drachms of sulphuret of potash to a pint of water; or from ten to twenty drops of any of the mineral acids to a pint of water, also to be constantly applied. Lotions also of sulphate of copper, nitrate of silver, and of nearly all the stimulant and astringent salts, have been employed, and sometimes with success; and in most cases of the disease, all these will have to be tried in turn, till one, being found beneficial, is continued till the cure is completed, or till it has ceased to do good, when it must be changed for another. Internal medicines must be employed if there be any symptoms indicating their necessity; but generally they are useless.

Porrigo scutulata, which is more commonly termed *ringworm* than the preceding, appears in the form of circular red patches, with numerous minute yellow pustules with depressed centres, out of which a hair usually projects, and which are attended by great itching. The fluid contained in the pustules dries up soon after they are formed, and, by coalescing, they produce a scab over the whole diseased surface. Subsequently successive crops of new pustules form around the margin of the scab, which is increased by their drying, and thus the disease may spread over the greater part of the scalp by the meeting and coalescing of the patches, which were at first isolated. The hair usually falls off from the part affected, or is so loosened that it may be pulled out without pain.

This form of porrigo sometimes appears spontaneously in poor and dirty children, but it is usually produced by contagion. The suggestions for its treatment must be the same as for Porrigo favosa.

PORSE'NA, or **PORSE'NNA,** a Lar (or mighty lord) of the Etruscan town of Clusium, with whom we are made acquainted in the early history of Rome. When the Tarquins, in the second year after their expulsion (508 B.C.), had been defeated near the forest of Arsia, they sought, as we are told, the assistance of Lar Porsena. (Liv., ii. 9.) According to Livy, the Etruscan prince immediately marched with his army against Rome, which was thrown into the greatest consternation. The Tarquins themselves however are entirely lost sight of in the narrative of the events which ensued. Porsena appeared with his overwhelming forces before the Janiculum, and the Romans, who had fortified themselves here, fled back to the Tiber. The defence of the bridge (Pons Sublicius) was entrusted to Horatius Cocles, who bade his companions retreat across the bridge and break down the part behind him, while he resisted the hosts of the Etrurians at the western end. His request was obeyed, and when the bridge was broken down, Horatius, after having prayed to father Tiberinus, threw himself into the water, and swam across amidst the darts of the enemy. Porsena, having thus failed in his attack, laid siege to the city, garrisoned the Janiculum, and pitched his camp on the banks of the river. The Romans at first kept within the city, and drove all their cattle within the walls. But the consuls P. Valerius and T. Lucretius devised a stratagem by which the Etruscans were drawn into a snare and suffered great loss. The siege however continued, and Rome suffered from famine. A Roman youth of noble birth, C. Mucius, who was indignant at the sufferings of his countrymen, went, with the approbation of the senate, across the Tiber with the intention of killing the invading king. Disguised and armed with a dagger, he found his way into the tent of Porsena, but mistaking the secretary of the king for the king himself, he killed him. Being seized by the king's attendants, he frankly declared his intentions, and added that he was not the only Roman youth that aimed at the king's life. Upon this the king threatened to burn him alive, unless he revealed his associates. But Mucius, to show to the king that he did not fear bodily suffering, thrust his right hand into a fire which happened to be burning upon an altar. The king, admiring the intrepidity of the young man, ordered him to be removed from the altar, and gave him his liberty. Mucius then told the king that there were three hundred noble Romans who had bound themselves by an oath to kill him, and that it had been his lot to make the first attempt. Upon this Porsena offered peace to the Romans on condition that they should give back to the Veientines their territory; the Janiculum was also evacuated upon the delivery of hostages. Porsena returned to Clusium, leaving to the famished Romans his well-stored camp.

The inconsistencies and incongruities of this story have been pointed out by Beaufort and Niebuhr. We have however several statements from which we may gather some glimpses of the real course of events so much disfigured in the narrative of Livy. Tacitus (*Hist.*, iii. 72) says that the city was taken by Porsena, a fact which at once throws light upon the whole transaction. From Pliny (*Hist. Nat.*, xxxiv. 39) we learn that the Romans were prohibited by Porsena from using iron for any other purpose than agriculture; and another proof of the entire submission of Rome to the foreign conqueror is implied in the story (Dionys. Hal., v. 35) that the senate sent to him an ivory throne and other insignia of royalty. These circumstances place it beyond doubt that for a time the Etruscan king was master of Rome. In the Roman tradition the truth is entirely distorted, and the whole affair between the Romans and Porsena is represented as a series of generous and magnanimous actions on both sides.

After Porsena had left Rome with his hostages, consisting of a number of maidens and youths, Cloelia, one of the maidens, effected her escape at the head of her female companions. The Romans, faithful to their treaty, sent her back, but the king, no less generous than the Romans, not only gave her liberty, but allowed her to select from the young male prisoners all those whom she might wish to restore to freedom. The accounts in Dionysius (v. 33), Plutarch (*Publ.*, 19), and Pliny (*Hist. Nat.*, xxxiv. 13), are somewhat inconsistent with one another. After his return to Clusium, continues the legend, Porsena sent his son Aruns with an army against Aricia, then the principal town of Latium, that it might not appear as if his former campaign had been entirely useless. The fact however seems to be, that being in possession of Rome, he wished to make himself master of all Latium. The Aricines were at first dismayed, but they asked and obtained aid from other Latin towns, and from Cuma in Campania, and thus gaining fresh confidence, they ventured on a battle. But the first attack of the Etruscans was so violent that the Aricines themselves were put to flight; the Cumans however attacked the enemy from behind, and defeated him. Aruns fell, and with him the greater part of his army. Those who escaped sought a refuge at Rome, where they were kindly received, and a district (Vicus Tuscus) was assigned to those who wished to settle there. It was not until this event that Porsena, according to the legend, sent envoys to Rome for the purpose of restoring the Tarquins to their country. But receiving for answer, that the liberty which Rome had once gained could only cease with the existence of the city, and that she would throw open her gates rather to an enemy than to Tarquin, he did not urge his demand, sent back those hostages who were still in his possession, and restored to the Romans the district of the Veientes, which had been taken from them by the treaty of the Janiculum. The peace between Porsena and the Romans was never interrupted, and from this moment we lose sight of the Etruscan king in the history of Rome. It is highly probable that he retained the sovereignty of Rome till the defeat at Aricia, when the Romans seem to have regained their independence. It must therefore have been after this event that the property of the king which was found in the city was publicly sold. This sale gave rise to the symbolical custom of selling the goods of King Porsena, which continued down to the time of Livy (ii. 14).

Porsena was probably a fabulous hero of the Etruscans, belonging to an age much anterior to any of which we have historical records. The Roman legends however have interwoven his name with the war against the Etruscans which the Tarquins are said to have caused soon after their expulsion. How little Porsena belongs to real history may be concluded from the fabulous account of his monument, a building as inconceivable as any described in the 'Arabian Nights.' (Niebuhr, *Hist. of Rome*, i., note 465, compared with p. 551.)

PORSON, RICHARD, was born at East Ruston, Norfolk, on the 25th of December, 1759. His father, Mr. Huggin Porson, who was the parish-clerk of his native place, taught him reading and writing at the same time, by drawing letters on a board or on the sand, and making the boy pronounce the corresponding sound and imitate the figure which expressed it. He also taught him to solve questions of arithmetic without the help of a slate or a copy-book, and thus laid the foundation of that extraordinary memory for which Porson was afterwards so celebrated. At nine years of age Richard Porson was sent, together with his younger brother Thomas, to the village school, kept by Mr. Sumner, an excellent writing-master, to whom Porson was indebted in some measure for his beautiful hand-writing. He stayed three years at this school, when his abilities and diligence attracted the observation of Mr. Hewitt, the vicar of the parish; from this gentleman Porson and his brother Thomas received gratuitous instruction in Greek and Latin for about two years, and the progress of the elder brother was so astonishingly rapid that he was mentioned to all the neighbouring gentry as a village prodigy. One of them, Mr. Norris of Grosvenor Place, was induced to send for Richard Porson, and after examining him in the closest and most rigorous manner, very liberally sent him to Eton, where he was placed on the foundation, at his own expense, in August, 1774. Porson was then in his fifteenth year, and he remained at Eton just three years, respected and admired by all who knew him. The death of his patron Mr. Norris fortunately did not affect his prospects: for Sir George Baker, the eminent physician, and some other friends of his late benefactor, collected a small income for him, which enabled him to continue at Eton, and he was afterwards sent to Trinity College, Cambridge, under the same kind patronage, in 1777. According to Dr. Goodall, late provost of Eton College, Porson knew little Greek when he went to Eton, and his compositions while at that school, though very correct, fell far short of excellence, and were very inferior to those of several of his contemporaries. He was placed as high in the school as he could be, but he was not elected to King's College, Cambridge. However, when he left Eton, contributions were readily supplied by Etonians in aid of Sir George Baker's proposal to secure the funds for his maintenance at the University. (*Minutes of Evidence before Select Committee on Education of Lower Orders*, 1818.)[*] At Cambridge he maintained and increased the reputation which he brought with him from Eton. In 1781 he was elected to a university scholarship on Lord Craven's foundation, one of the greatest honours within the reach of an under-graduate; and on taking his degree in the following year, he was third senior optime in mathematics and senior medallist in the classical competition which followed. He was elected a fellow of his college in October, 1782, being one of the very first who ever obtained that distinction in the year of his B.A. degree. Some scruples which he felt with regard to the subscription of the Thirty-nine Articles deterred him from taking orders, and, according to the rules of the college, he consequently vacated his fellowship in 1791, and was thus again left unprovided for. His friends however again came forward to support him, and in 1793 he was elected Regius Professor of Greek in the university of Cambridge; the small salary attached to this office, and an annuity of 100*l.* for life, which Mr. Cracherode and some other liberal friends had purchased for him, removed him from the pressure of immediate want, and it is thought that he would have added to his income by delivering lectures to the university had there not been some obstacle to his obtaining rooms in Trinity College, where he wished to reside.

---

[*] King's College, Cambridge, consists of a provost and seventy fellows and scholars. Vacancies occur among the latter through death, marriage, and presentation to a King's living. But as the number of seventy must always be kept up, as soon as there is a vacancy, the senior colleger at Eton is immediately sent to Cambridge. He remains for three years a scholar, after which he is admitted to his fellowship and B.A. Every year, at election, in the end of July or beginning of August, the provost of King's, accompanied by two Posers, comes to Eton. The senior collegers are then examined, and a certain number of them, about twelve, are placed on the indenture. These boys go off to King's in succession, that is, in the order in which they stand on the indenture, whenever, in the course of the year, a vacancy, which at Eton is called a resignation, occurs at King's. If the number of boys on the indenture exceeds the number of vacancies which have occurred in the course of the election year (from August to August), those who remain are superannuated, unless they have not attained the age of nineteen on Election Monday, in which case they are allowed a second chance. This was the case with Porson; he was superannuated. When he was admitted on the Eton foundation he was placed, as Dr. Goodall says, as high in the school as he well could be; but he did not reach the sixth form in time, so as to be placed on the indenture at the proper age. The examination of the Posers merely went to ascertain that the senior boys had a sufficient knowledge to qualify them to be admitted to King's, in the case of a vacancy. They were not brought into competition with each other by the Posers; their qualifications being proved (and the standard was a low one), they were placed on the indenture, exactly in the same order as that in which they stood on the Eton list. Indeed it seldom happened that a boy on the foundation lost places in his progress through the school. A lad well placed,

In 1795 Porson married Mrs. Lunan, a sister of Mr. Perry, editor of the 'Morning Chronicle.' Unfortunately this lady died about two years after, and the effect of her loss upon Porson's mind seems to have produced those habits of intemperance to which, as is too notorious, this great scholar was much addicted in the latter part of his life. Mr. Perry however continued to be the warmest friend that Porson possessed, and his time was from henceforth generally spent either at the 'Morning Chronicle' office or at Mr. Perry's country-house at Merton.

On the establishment of the London Institution, Porson was appointed head librarian at that establishment, with a salary of 200*l.* a year, and was of great service in selecting a classical library. It was not however a sufficiently wide sphere of action for such a man as Porson, and it is to be regretted that he never was employed in any public situation equal to his abilities, and likely to have called forth the energies of his mind. During the last years of his life he suffered much under a complication of disorders, produced partly by his irregular habits, and partly by his aversion to medical advice. In 1808 his prevailing disorder was asthma, which was succeeded by intermittent fever. On Monday, the 19th of September, he was attacked by apoplexy, in the street, and he had another attack on the following day. He lingered till the Sunday following (25th September, 1808), when he expired. His remains were conveyed to Cambridge, and solemnly interred in the antechapel of Trinity College, where a monument has been raised to his memory, and a bust by Chantrey has been erected.

Richard Porson was one of the profoundest Greek scholars, certainly the greatest verbal critic, that any age or country has produced. He possessed every quality which is considered necessary to the formation of a classical scholar. A stupendous memory, unwearied application, great acuteness, strong sound sense, and a lively perception both of the beautiful and of the ridiculous. Besides these qualifications, he enjoyed the rare faculty of guessing or conjecturing, from the imperfect data of corrupt readings, the very words of the author whose text he sought to restore; in this last particular we know of no one, with the single exception of Bentley, who can be named in comparison with him; and in some points we should not hesitate to place Porson before that great Aristarchus of criticism. It is a common mistake to suppose that Porson's reading was confined to the Greek poets, or did not extend much beyond the ordinary range of classical authors. We doubt if there was any classical author whom he had not read, and we are confident that he was familiar with the whole mass of Greek literature. We have looked through the editions of Greek books which belonged to him, and which are now in the hands of different individuals or in public libraries, and there is not one which does not bear some trace of his careful and critical perusal. He was besides an excellent French scholar, and was well versed in the literature of his own country. His English style was terse and elegant, and his 'Letters to Travis' convince us that he would have held a high place among English writers if he had directed his attention to the more popular branches of literature. From some traces which we have observed here and there, we are disposed to believe that Porson would have been a great general philologer had he lived some years later, and had an opportunity of turning his attention to the linguistic studies of modern scholars. As it was, he paid some attention to Anglo-Saxon, and it was perhaps only from want of means that he did not apply himself to a wider range of comparative philology. The great complaint which we have to make against Porson is, that with such vast capabilities he did so little. With the exception of reviews and other fugitive essays, he published nothing himself besides the 'Letters to Travis,' just mentioned, and a critical edition of four plays of Euripides. His edition of the Lexicon of Photius [Photius], and his 'Adversaria,' were published after his death. Perhaps however we should have no right to complain of this, if it were not for the consequences which have sprung from it. Porson's great reputation during his lifetime converted all the promising young scholars of the time into servile imitators of the great critic, and the 'Porsonian school of critics,' as they have been termed, threw many impediments in the way of sound and comprehensive scholarship. Every one was inventing some new canon, and then altering the text of Greek poets accordingly, to suit his own rule. It is not possible in this place to enter at length on such a question as this; but most Greek scholars will, we think, admit that much harm, or at least little good, has resulted from this close and narrow imitation of Porson; and that it would have been better if his successors had endeavoured rather to do what he omitted to do, but might have done, than to confine themselves to the narrow limits of his actual performances.

PORT GLASGOW. [Glasgow.]

PORT LOUIS. [Morbihan.]

PORT MAHON. [Menorca.]

PORT ROYAL. [Jamaica.]

PORT ROYAL DES CHAMPS, a celebrated convent of nuns, which was situated not far from Versailles, on the left of the high road leading from Rambouillet to Chartres. The site of the convent is a deep vale, enclosed by hills. In the antient charters the place is called Porrigium, Porregum, Portus Regius, Porrois, and Porréal. The name dates from the time of Philippe Auguste, about the beginning of the thirteenth century, who having once lost his way while hunting, found in this sequestered valley a shelter, 'port,' for himself and his attendants. The monastery was founded about 1204, with a donation made by Matthieu de Marli, of the family of Montmorency, when he was going to set out for the Holy Land. The nuns were of the order of St. Bernard, and had their own abbess. In 1223 the pope conferred on the convent the right of affording an asylum to such lay personages as, being disgusted with the world, and being their own masters, should wish to live in monastic seclusion without binding themselves by permanent vows. By a papal bull, the nuns had the right of choosing their abbess without any interference on the part of the bishop of the diocese.

The important period of the history of Port Royal begins with the appointment of Angelica Arnauld, sister of the famous controversialist Antoine Arnauld. Angelica was a mere child when she was appointed, through family interest, to be coadjutrix of the abbess Jeanne de Boulehard, about the year 1600. In 1602 Boulehard died, and Angelica, then not quite eleven years old, was consecrated abbess. She was of course assisted in the exercise of her office by the older nuns. As she grew to womanhood, she conceived the plan of a reform in the discipline of the convent, which had grown rather loose, and she carried it into execution. The leading features of this reform were a community of goods, absolute silence, abstinence from meat, rigid seclusion, ascetic exercises, and the infliction of penitential mortification. In 1626 Angelica removed with her nuns to a house in the Fauxbourg St. Jacques at Paris, on account of an epidemic which raged at Port Royal des Champs, and which was attributed to the dampness and unhealthiness of that district. In 1633 a new and more spacious house was purchased for the monastic establishment at Paris, in the Rue du Boulai near the Rue Coquillière, and the church was consecrated by the archbishop of Paris with great solemnity

---

according to age and number, on the lower forms of the school, was pretty sure of being sent to King's College, after a lapse of eight, ten, or even twelve years, if his conduct was respectable. A great change has lately taken place in this respect. The foundation boys are not only brought into competition with each other and the Oppidans, but they gain or lose places, according to merit, on their taking steps. The senior boys, who are brought before the Posers, are in future to be considered as having no place, and are to be registered on the final indenture, according to their merit, after a strict examination.

The new convent was called Port Royal de Paris. The building of Port Royal des Champs, which continued to belong to the same monastic institution, was occupied afterwards by several pious and learned men who wished to live a secluded life according to the spirit of the papal bull of 1223, and who were styled 'les Solitaires de Port Royal.' This was the origin of the famous school of Port Royal. One of the first of these recluses was Claude Lancelot, the grammarian. He was joined by Antoine le Maistre, a distinguished advocate, and his brother Louis Isaac le Maistre de Sacy, by Antoine Arnauld, brother of the abbess Angelica, by Pierre Nicole, Nicolas Fontaine, Thomas du Fossé, and others. [ARNAULD, ANTOINE.] They were most of them friends and disciples of Du Verger d'Hauranne, abbot of St. Cyran, well known for his controversies with the Jesuits, and his connection with Jansenius, who had been his school-fellow at Louvain. Le Maistre de Sacy was for a time spiritual director of the nuns of Port Royal de Paris. Lancelot and his friends established a school at Port Royal des Champs for the better religious, moral, and scholastic instruction of a limited number of pupils. They objected above all to the lax morality of the Jesuits, and to their method of education, which admitted no improvement. The school of Port Royal consisted of five classes of five pupils each. Lancelot, Arnauld, De Sacy, Nicole, Fontaine, and others were the teachers, and they published in concert a number of school-books which have ever since maintained a reputation. The school of Port Royal flourished from 1646 to 1660. It formed many distinguished pupils; Racine and Tillemont were of the number. Among the school-books that were published for the use of that institution the following deserve especial mention: 1, 'Nouvelle Méthode pour apprendre la Langue Latine.' 2, 'Nouvelle Méthode pour apprendre la Langue Grecque.' 3, 'Jardin des Racines Grecques.' 4, 'Grammaire Générale.' 5, 'Elémens de Géométrie.' All these works were written conjointly by Lancelot, Arnauld, and Sacy.

In the mean time the number of nuns and novices of Port Royal de Paris having greatly increased, the abbess Angelica Arnauld determined upon transferring part of them to Port Royal des Champs. Upon this the school of Port Royal was removed from the latter place to Paris, Rue St. Dominique, Fauxbourg St. Jacques, but after three years the teachers were restored to Port Royal des Champs, where they no longer occupied the monastic building, but a farmhouse, called Les Granges, on the neighbouring hill.

In 1653, Pope Innocent I. having condemned five propositions in the book of Jansenius [JANSENISTS], Arnauld wrote to prove that these propositions did not exist in the book of Jansenius, at least not in the sense attributed to them. Upon this Arnauld was accused of Jansenism, and strange to say, the nuns of Port Royal, with their abbess Angelica, took part in this controversy, and declared that they could not see the five alleged heretical propositions in the work of Jansenius. At last an order came from the king, in 1660, to suppress the school and drive away the boarders from Port Royal des Champs. The nuns continuing refractory, Perefix, archbishop of Paris, sent a party of police-officers, in 1664, who arrested the abbess, the prioress, and other nuns, and distributed them among several monasteries, where they were kept in a state of confinement. Meantime some of the nuns who had remained at Port Royal de Paris intrigued with the government in order to become independent of Port Royal des Champs, and Louis XIV. appointed a separate abbess to Port Royal de Paris. In 1669 a compromise was made between the pope and the defenders of Jansenius, which was called 'the peace of Clement IX.' The nuns of Port Royal des Champs with their own abbess were then restored to their convent, but Port Royal de Paris was not restored to them; a division of property was effected between the two communities, by order of the king, which was confirmed by a bull of Clement X. dated 1671. Each convent retained its own abbess. Several disputes took place between the two communities, in which the archbishop of Paris and the Jesuits took an active part.

At last, in March, 1708, a bull of Pope Clement XI. suppressed the convent of Port Royal des Champs and gave the property to Port Royal de Paris. (*Lettres des Religieuses de Port Royal des Champs au Pape, au Roi, et à Messieurs les Cardinaux de Noailles et d'Etrées touchant les Bulles de notre Saint Père le Pape Clément XI. du 27 Mars, 1708, portant suppression du titre de l'Abbaye de Port Royal des Champs et union des biens qui en dependent au Monastère de Port Royal de Paris.*) In 1709 D'Argenson, the lieutenant-de-police of Paris, was sent with a body of men to Port Royal des Champs, and he removed from thence the nuns, who were distributed among several convents. The convent and church of Port Royal des Champs were stripped of all their valuables, which were transferred to Port Royal de Paris, and the former building was levelled with the ground, by order of Louis XIV., as a nest of Jansenists and heretics. Gregoire has written a work styled 'Les Ruines de Port Royal,' 1809, in which he describes the present appearance of the place. Besoigne, Racine, Clémencet, Du Fossé, and others have written Histories of Port Royal. Dr. Reuchlin has lately published an elaborate 'Geschichte von Port Royal,' Hamburg, 1839.

The most distinguished men of learning connected with Port Royal are—1, Claude Lancelot, born at Paris in 1615. He was a disciple of Du Verger d'Hauranne, came to Port Royal in 1638, and was one of the founders and promoters of the school. After its dispersion, Lancelot acted as preceptor to several young noblemen in succession; he afterwards retired to the convent of St. Cyran, which being suppressed in 1678, on suspicion of Jansenism, Lancelot was sent into exile at Quimperlé, where he died in 1695. Goujet, in his edition of the 'Mémoires de St. Cyran, par Lancelot,' gives a biographical notice of the latter, and a list of his works. 2, Louis Isaac le Maistre de Sacy was also a disciple of Du Verger d'Hauranne, took priest's orders, and withdrew to Port Royal, where he became spiritual director to the nuns, and gave up his property to the monastery. In 1661 he retired to Paris with his friends Nicolas Fontaine and Thomas du Fossé. In 1666 they were all three arrested, and confined to the Bastille, where Le Maistre remained three years. During his confinement he began his translation of the Bible: 'La Sainte Bible,' in Latin and French, with explanations, which was completed after his death by Du Fossé. He also translated Terence and Phædrus into French, and wrote other works in French, both in prose and verse. He returned to Port Royal in 1675, but was ordered by the government to quit it in 1679, when he went to live at the house of his cousin the marquis of Pomponne, where he died in 1684. His brother Antoine le Maistre had died before him at Port Royal des Champs. He wrote several controversial works. 3, Pierre Nicole, born at Chartres in 1625, studied at Paris, and afterwards became one of the professors in the school of Port Royal. In 1655 he returned to Paris, where he contributed to Pascal's work, 'Les Lettres Provinciales.' [PASCAL.] Persecuted on the score of Jansenism, he took refuge in Belgium, but afterwards returned to Paris, where he published his 'Essais de Morale,' which established his reputation as a writer and as a moralist. He also published—1, 'Epigrammatum Delectus ex omnibus tum veteribus tum recentioribus Poetis,' Paris, 1659; 2, 'La Perpetuité de la Foi de l'Eglise Catholique touchant l'Eucharistie,' 1664, against Claude, the Calvinist divine; 3, 'De l'Unité de l'Eglise,' being a refutation of Jurieu, another Calvinist divine; 4, 'Etudes de Morale et Instructions Theologiques,' and other religious works.

PORT, a Portuguese wine, the produce of the vineyards of the Upper Douro. For several centuries, and more particularly after the Conquest, the wines of France were almost the only kinds imported into England. In 1669 the consumption of those wines in England amounted to two-fifths of the whole quantity imported, the duty at that time being the same on the wines of France and Portugal. A distinction was made in the duties in 1693, and a higher rate was levied upon French wines. In 1697 the duty on French wines was again increased, and they were charged at the rate of 4*s.* 0½*d.* per gallon, while the duty on Portuguese wine was only 1*s.* 8*d.* In 1703 a treaty between England and Portugal was negotiated by Mr. Methuen, by which we engaged to admit Portuguese wines at a duty of one-third less than that on French wines, Portugal being bound to receive English manufactured goods at one-half less duty than that levied upon the manufactures of other countries. From this time the fiscal difference of the tariff has been at all times so great, often amounting to 100 per cent., as completely to alter the national taste, and the wines of the Upper Douro have been those chiefly consumed in England. From 1707 to 1779 the proportion of French and Portuguese wines imported was 5 per cent. of the former, and 95 per cent. of the latter. In 1784, of the total quantity of every description of wine imported, the proportion was 80 per cent. of Portuguese wines, and 20 per cent.

of those from all other countries: in 1790 the proportion continued much the same, being 77 per cent. and 23 per cent., and of the latter proportion 18 parts out of 23 consisted of Spanish wines. The Portuguese monopolists of course treated their customers as all monopolists do, charging an extravagant price for their wines, and attending but little to the improvement of their quality. On the establishment of the Oporto Wine Company in 1754, the extent of the vineyards was diminished with a view of making the most of their privileges at the least possible trouble. To this system England submitted until within a comparatively recent period. In 1782 Portugal agreed to admit other articles coming from England besides her manufactures at a duty of one-half per cent. less than was paid by other countries; but England was the only customer for Portuguese wines, and, with the exception of Brazil, they scarcely found their way into any other country. The following table, exhibiting the total quantity of wine exported by the Oporto Company, distinguishing the quantity sent to England, is given on the authority of a note in No. 3 of the 'Foreign Quarterly Review':—

Years.		Total Quantity exported.	To England.
1818	.	32,843 pipes.	32,465 pipes.
1822	.	27,758 „	27,470 „
1825	.	40,254 „	40,277 „
1826	.	18,604 „	18,310 „

The natural taste and quality of the wines of the Upper Douro are unknown in England, and probably would not be relished. They are strongly flavoured for the English market, and require to be kept some years in the wood and in bottle before they attain the qualities which render port-wine a favourite beverage with wine-drinkers in England.

In 1819 a reduction was wisely made in the duty on French wines, with the best effects upon the revenue, besides the advantage of promoting a commercial intercourse with France; and in 1831 this improvement in our commercial policy was followed by an act equalising the duty on all foreign wines. This has induced Portugal to revise her tariff, and the imports from England are now placed upon the same footing as those from other countries. The change was made in April, 1834, and an account of it is given in a parliamentary paper printed in the same year (No. 318). In the following month the privileges of the Oporto Wine Company were abolished; but they have since been restored. At all events the wine-trade with Portugal does not now depend upon high duties directed against the wines of other countries, although it will for a long period be sustained by the taste which they have tended to create. The consumption of French wines will probably increase, and the new commercial treaty with France, which Mr. Porter, of the Board of Trade, proceeded to Paris with full powers to sign during the present month (September, 1840), will have a more extensive influence upon the trade of the two countries. The following tables exhibit the extent of the wine-trade with Portugal during the last twenty years.

1. Quantities of wine annually imported into the United Kingdom from Portugal on an average of each of the five years ending 1824, 1829, 1834, and 1839; also quantities of the same exported from the United Kingdom for the same periods:—

Average of Years.		Imported.	Exported.
1820-1-2-3-4	.	2,822,061 galls.	205,749 galls.
1825-6-7-8-9*	.	3,558,252 „	240,933 „
1830-1-2-3-4	.	2,784,545 „	245,185 „
1835-6-7-8-9	.	3,491,684 „	320,017 „

2. Duties: Years in which alterations were made in the duties on Portuguese, Spanish, and French wines, and rate of the same per gallon:—

Years.			Portuguese and Spanish.		French.	
			s.	d.	s.	d.
1820	.	.	9	1¼	13	9
1825	.	.	4	9¾	7	2½
1826	.	.	4	10	7	3
1831	.	.	5	6	5	6

3. Proportion per cent. of the consumption of the principal kinds of wine consumed in the United Kingdom at different periods:—

Years.	Portuguese.	Spanish.	French.	Madeira.	Cape.
1820 to 1824	50·9	21·8	3·6	7·2	11·5
1825 to 1830	47·	28·2	5·7	4·1	9·2
1831 and 1832	43·	34·2	4·	3·	8·7
1838 and 1839	41·5	36·	5·7	1·6	7·5

The consumption of wine is less than it was half a century ago, notwithstanding the increase of the population in wealth and numbers. [Wine-Trade.] This has not arisen from the increased consumption of malt liquor [Malt], but from the great increase in the use of British spirits. [Spirit-Trade.]

4. Quantities of Portuguese wines retained for home consumption in each of the following years, showing the proportion per cent. to the total quantity of all kinds on which duties were paid for consumption:—

Years.	Gallons.	Proportion per Cent.	Years.	Gallons.	Proportion per Cent.
1820	2,361,461	51·4	1830	2,869,608	44·5
1821	2,343,509	50·	1831	2,707,734	43·6
1822	2,375,210	51·3	1832	2,617,405	46·7
1823	2,492,212	51·4	1833	2,596,530	41·8
1824	2,512,343	49·9	1834	2,780,303	42·
1825	4,200,719	52·4	1835	2,780,024	43·4
1826	2,833,688	46·7	1836	2,878,359	42·2
1827	3,222,192	47·1	1837	2,560,252	40·
1828	3,307,021	46·1	1838	2,900,457	41·4
1829	2,682,084	43·1	1839	2,998,152	41·4
Average	2,833,043	49·0	Average	2,768,882	43·0

5. Quantities of Portuguese wines warehoused under bond in the United Kingdom on the 5th of January in each of the following years. It may be observed that the increased quantity bonded may be solely occasioned by additional facilities for bonding:—

Years.	Port of London. Galls.	Other Ports. Galls.	Total. Galls.	Total all Sorts. Galls.
1833	1,442,868	1,312,572	2,755,440	7,975,897
1834	906,335	1,187,835	2,094,170	7,526,967
1836	2,397,186	1,819,718	4,216,904	9,776,140
1837	2,902,735	2,081,165	4,983,900	10,568,319
1838	2,838,617	1,997,766	4,836,383	10,727,447
1840	2,768,956	1,997,553	4,766,509	11,233,744

PORTA, GIAMBATISTA, was born of an antient and noble family at Naples, about the year 1550. He applied himself very early to the study of nature, and was deeply read in Aristotle, Pliny, and all the antients who in any way treat of nature or describe the earth. It is said that at the age of fifteen he composed the first books of his 'Natural Magic;' but as he derived his opinions from such authors as Arnold de Villanova and Cardan, he mixed up numerous fantastic and delusory notions with the deductions of real science. It appears from his writings that he travelled through Italy, France, and Spain, visiting all the libraries and learned men, and conversing with artists on matters relating to their several professions. His publications widely extended his fame. A suspicion of his being addicted to unlawful superstitions, countenanced by some of his works, was however the cause of his falling under the censure of the court of Rome, which obliged him to appear there in person to justify his conduct and opinions. The result of the examination was the prohibition of the meeting of any more of the literary assemblies held at his house, on account of their being accused of having occasionally discussed the secrets of magic. This society was called 'I Secreti,' and was accessible only to such as had made some new discoveries in physical science: even after its dissolution his house still continued to be the resort of literary men, both foreign and Neapolitans. He not only established private schools for particular sciences, but to the utmost of his power promoted public academies, and had no small share in establishing that of 'Gli Oziosi' at Naples. In his old age he composed dramas, both tragic and comic, which had some success at the time, but are now quite forgotten. He died, unmarried, at Naples, February 4, 1615, and was buried in a white marble chapel that he had built in the church of St. Laurence.

In spite of the strange and childish absurdities that abound in Porta's works, it cannot be denied that he was of greater service to physical science than perhaps any of his contemporaries. It is to him that we owe the invention of the camera obscura, and also of a great number of curious optical experiments. He has written much on the subject of plane, concave, and convex mirrors, and particularly on the burning-glass, which he flattered himself he could construct in such a manner as to be able to burn at any distance. The most important invention that has been attributed to him is that of the telescope, of which he has by some persons been supposed to be the author, on account of a passage in the tenth chapter of the seventeenth book of his 'Natural Magic;' but by the best judges this honour is still considered to be due to Galileo. [GALILEO.]

---

* The importations of the year 1825 exceeded by 2,130,065 gallons the annual average quantity imported in the preceding quinquennial period.

The following is a list of his extant works:—1, 'Perspectiva,' Rome, 1555, 8vo.; 2, 'Magiæ Naturalis, sive de Miraculis Rerum Naturalium, Libri Viginti,' of which the first complete edition was published at Naples, 1589, fol. The Naples edition of 1558, fol., is very rare, and contains only three books; that of Antwerp 1561, 8vo., contains four. It has been often reprinted, and translated into several modern languages; into English, for instance, so late as 1658. This work contains a great number of curious facts that were not generally known at that time concerning the properties of plants, metals, animals, &c.; and also the most remarkable human inventions. It is a vast compilation of passages extracted from authors both antient and modern, and put together without taste or judgment; but it contains a great number of interesting observations on light, mirrors, telescopes, fireworks, statics, mechanics, &c. 3, 'De Furtivis Literarum Notis, vulgo de Zifaris,' Naples, 1563, 4to., several times reprinted, with the addition of a fifth book. This is a sort of stenography, or rather a treatise on different modes of secret writing, of which one hundred and eighty are explained, and a method proposed by which they can be multiplied ad infinitum. 4. 'Phytognomonica Octo Libris Contenta, in quibus nova facillimaque affertur Methodus quâ Plantarum, Animalium, Metallorum, Rerum denique omnium ex primâ extimæ Faciei Inspectione quivis abditas Vires assequatur. Accedunt ad hæc confirmanda, Infinita propemodum Selectiora Secreta, summo Labore, Temporis Dispendio, et Impensarum Jacturâ, vestigata explorataque,' Naples, 1583, fol., and several times reprinted. His object in this work is to point out the means of discovering the properties of plants by their analogy with the different parts of the body of animals. It is, as might be anticipated, full of absurdities, though Adanson calls it an ingenious system, and says that the work contains at least as much truth as falsehood. (*Familles des Plantes*, préf. xi.) 5, 'De Humanâ Physiognomoniâ,' Sorrento, 1586, fol.; and in Italian, Naples, 1598, fol., very frequently reprinted, and translated into different modern languages. This is the work by which he is best known, and which gives him a right to be considered as the true founder of physiognomy. After establishing the influence that the mental affections exercise upon the body, he treats of the differences of each part of the human frame, and declares the signs which disclose the character of the individual. He has made great use of the observations of Aristotle, Polemo, and Adamantius; but he has also added a great many curious remarks of his own. He considers that the human face should be compared with that of animals; that as there exists in the human race as many modifications as there are individuals, and as also the different degrees of his organization recall those at which nature stops permanently in some of the inferior vertebrated animals, the general configuration of the head of man must express a character akin to that which is found in these same animals, according as the intellectual dispositions of the individual agree with those that characterise them. Accordingly, in the plates inserted in his work, he has compared the head of Vitellius with that of an owl, Plato's with that of a greyhound, &c. 6, 'Villæ Libri Duodecim: i., Domus; ii., Sylva Cædua; iii., Sylva Glandaria; iv., Cultus et Insitio; v., Pomarium; vi., Olivetum; vii., Vinea; viii., Arbustum; ix., Hortus Coronarius; x., Hortus Olivarius; xi., Seges; xii., Pratum: in quibus majori ex parte cum verus Plantarum Cultus, certaque Insitionis Ars et prioribus Sæculis non visos producendi Fructus Via monstratur, tum ad Frugum, Vini, ac Fructuum Multiplicationem Experimenta propemodum infinita exhibentur,' Francof., 1592, 4to. A learned and agreeable work, the contents of which are sufficiently expressed by the title-page. 7, 'De Refractione, Optices Parte, Libri Novem,' Naples, 1593, 4to. Among many things that are vague and inexact, are found now and then some just observations on a great number of objects relating to optics, such as refraction and the anatomy of the different parts of the eye. The seventeenth book of his 'Natural Magic' contains a portion of this treatise. 8, 'Pneumaticorum Libri Tres; cum Duobus Libris Curvilineorum Elementorum,' Naples, 1602, 4to., and in Italian, ibid., 1606, 4to. In this work he treats of hydraulic machines and their construction, and enters into great detail. A new edition of his 'Curvilinear Geometry' was published at Rome, 1610, 4to., with the addition of a third book, treating of the quadrature of the circle, the solution of which famous problem he flattered himself that he had rendered more easy. 9, 'De Cœlesti Physiognomiâ Libri Sex,' Naples, 1601, 4to., and frequently reprinted. In this work, though he rejects judicial astrology, he attributes nevertheless great influence to the heavenly bodies. 10, 'Ars Reminiscendi,' Naples, 1602, 4to. A collection of all the means of assisting and strengthening the memory that were practised by the antients. 11, 'De Distillationibus Libri Novem, quibus certâ Methodo, multiplicique Artificio penitioribus Naturæ Arcanis detectis, cujuslibet Misti in propria Elementa Resolutio perfectè docetur,' Rome, 1608, 4to., and Strasbourg, 1609, 4to. A curious work, from giving an idea of the state of chemistry in the beginning of the seventeenth century. 12, 'De Munitione Libri Tres,' Naples, 1608, 4to. A treatise on fortifications. 13, 'De Aëris Transmutationibus Libri Quatuor,' Naples, 1609, 4to. This is said by M. Musset Pathay (*Bibliog. Agronomique*, p. 51) to be the first work on meteorology in which any sound ideas are to be found. 14, His dramatic works consist of fourteen comedies, two tragedies, and one tragi-comedy. The comedies were collected into four volumes, 12mo., and published at Naples, 1726. All these works are analysed by H. Gab. Duchesne, at the end of his 'Notice Historique sur I. B. Porta,' Paris, 1801, 8vo. (*Biogr. Univ.*, and *Biogr. Méd.*)

PORTAL VEIN. [LIVER.]

PORTARLINGTON. [QUEEN'S COUNTY.]

PORTCULLIS, in fortification, is an assemblage of several large pieces of wood, joined across one another like a harrow, and each pointed with iron at the bottom. They are sometimes hung over the gateways of old fortified towns, ready to let down in case of a surprise, when the gates could not be shut. (James's *Military Dictionary*.) The French, at a very early period, called it 'porte-coulant,' *i.e.* sliding gate, which is the true etymology of the word. 'Coulisse' is likewise used by the French writers for the portcullis, whence our term is immediately derived.

PORTER, a kind of malt liquor, extensively consumed in London. The malt used for porter is high-dried; that is, it has been exposed to greater heat in the kiln than the pale malt used for ale and beer. [BREWING.] Porter was first brewed in 1722. The malt liquor previously drank consisted of three kinds, ale, beer, and 'two-penny,' and a mixture of two of either of these kinds was a favourite beverage under the name of 'half and half;' or a mixture was drunk called 'three threads,' consisting of equal portions of each of the above kinds of liquor, for a draught of which the publican had to go to three different casks. About 1722, Harwood, a London brewer, commenced brewing a malt liquor which was intended to unite the flavours of ale and beer, or ale, beer, and twopenny; and having succeeded, he called his liquor 'entire,' or 'entire butt,' a name intended to intimate that it was drawn from one cask or butt only. A mixture of ale and porter drawn from different casks is very commonly drunk in London at the present time. Harwood's liquor obtained the name of 'porter' from its consumption by porters and labourers. From 1722 to 1761 the retail price of porter was 3*d.* per pot, when it was raised to 3½*d.*, at which it continued until 1799; it has never been higher than 6*d.*, nor during the present century lower than at the present time (September, 1840), when the price is 4*d.* The following account of the fluctuations of the price per barrel since 1816 is from a private source.—In July, 1816, the price was reduced from 45*s.* to 40*s.*, but in October was again advanced to 45*s.*; in Jan. 1817, a further advance was made to 50*s.*, and in December of the same year it reached 55*s.* In 1819, 1820, and 1822, the price was successively reduced from 55*s.* to 50*s.*, 45*s.*, and 40*s.* In January, 1824, it was advanced to 45*s.*; in November, 1825, to 50*s.*; but a few months afterwards it again fell to 45*s.* Since the abolition of the beer duties, in 1830, the price has been 33*s.* per barrel.

During the existence of the duties on ale and beer, porter was never distinguished in the returns of the quantity of malt liquor charged with the duty; and any estimate of the extent of its consumption must be taken with caution. The brewing of porter has not been very successfully practised in the country 'collections' in England; and the peculiar excellence of 'London porter' probably arises from the large scale on which all the processes connected with the brewing, particularly the vatting, are conducted, as well as the skill of the brewers. In Barclay's brewery there are about 120 porter vats, each capable of containing 3500 gallons. In London the brewing of porter is confined to the great brewers, the others being chiefly ale-brewers. At the largest brewery in London the proportion of porter brewed is between one-ninth and one-tenth; and in the London 'collection,' where above one-half the malt consumed by brewers and victuallers in England is used, the proportion is probably one-sixth of the whole, or about one million bushels. This porter is not all consumed in London; for the estimation in which the article is held renders it not only in demand in every part of England, but also for export abroad. Allowing one-sixth for exportation, and for the provinces, the proportion of porter consumed in London will be about one-half of the whole quantity of malt liquor consumed. It is said that the taste of the public has a tendency to diminish this proportion. Porter is bottled in large quantities, both for home and foreign demand. The Railway Commissioners for Ireland remark, in their Second Report (1838), 'that Irish porter is now largely exported to England, and the Dublin bottled porter successfully rivals the London porter, even in London itself.'

PORTEUS, BEILBY, an eminent English prelate, was born at York in 1731. He passed several years at a small school in his native city, and when he was thirteen years old he was removed to a school at Ripon. From this place he went at an earlier age than usual to Cambridge, where he was admitted a sizar of Christ's College. His personal worth, united with his superior attainments, both classical and mathematical, soon procured him a fellowship in his College, and by the active exertions of his friends he was made esquire-beadle of the University. This office he did not long retain, but he chose rather to give his undivided attention to private pupils. In 1757, at the age of twenty-six, he was ordained deacon, and soon after priest.

He first became known as a writer by obtaining Seaton's prize for the best English poem on a sacred subject. On this occasion the subject was 'Death,' and the production of Mr. Porteus was universally deemed one of great merit. In 1762 he was made chaplain to archbishop Secker. His first preferments were two small livings in Kent, which he soon resigned, and took the rectory of Hunton in the same county. He was next appointed prebendary of Peterborough, and not long afterwards, in 1767, he became rector of Lambeth. In the same year he took the degree of D.D. at Cambridge, and in 1769 was made chaplain to king George III., and master of the hospital of St. Cross near Winchester.

In 1773, Dr. Porteus, with a few other clergymen, applied to the bishops, requesting that they would review the Liturgy and Articles for the purpose of making some slight alterations. In taking this step they proceeded in a temperate and respectful manner, and the answer declining to entertain the application, which archbishop Cornwallis returned in his own name and in that of the bench in general, was marked with great kindness. Dr. Porteus and his friends acquiesced in the decision of the bishops, and thus the affair ended.

In 1776, Dr. Porteus, without the least solicitation on his part, was made bishop of Chester; and in 1787, on the death of bishop Lowth, he was promoted to the diocese of London, over which he very ably presided till his death. In 1798 he began a course of lectures on St. Matthew's Gospel, which he delivered at St. James's church on the Fridays in Lent, and which he afterwards published. These lectures have been perhaps the most popular of all his works. He died May 14th, 1808, in the seventy-eighth year of his age. Though bishop Porteus cannot be called a profound scholar or divine, he was a man of considerable learning and ability; and he pursued through life a steady course of pious exertion for the benefit of his fellow-creatures, which procured him a high reputation among men of all parties. His works, consisting of sermons and tracts, with a 'Life of Archbishop Secker,' and the poem and lectures already mentioned, were collected and published in 1811, in five vols. 8vo., with his Life, making another volume, by his nephew, the Rev. Robert Hodgson, now Dr. Hodgson, dean of Carlisle. (*Life*, as above; Chalmers's *Biographical Dictionary*.)

PO'RTICI. [NAPLES, Province.]

PORTICO. Originally applied without distinction to colonnades and covered ambulatories, the term is now limited to signify a sheltered space enclosed by columns at the entrance to a building; and unless otherwise expressed, roofed with a pediment, like the end or front of a Grecian temple. The term therefore, as now generally restricted, answers to the *Pronaos* of such a temple. Porticos are described according to the number of columns in front, viz. tetrastyle, hexastyle, octastyle, &c. [CIVIL ARCHITECTURE; PARTHENON.] They are called prostyle when, as generally happens, they project from the main building. Such as are *in antis*, and recessed within the front of the building, are technically called *loggias;* the latter term indeed is not always employed in this particular sense, but it would be convenient if it were, as much ambiguity would thereby be prevented. Although, too, a loggia so far resembles any other colonnade, it differs from the other in being situated, like a portico, at the entrance and in the centre of a façade, whereas colonnades are usually lengthened ranges of columns in other situations; thus we speak of the 'colonnades' of the Louvre, of Greenwich Hospital, and of the piazza of St. Peter's at Rome.

Pseudo-prostyle is a useful term suggested by Mr. Hosking for such an arrangement of columns beneath a pediment as resembles a prostyle in elevation, but which, instead of advancing forwards, forms merely a slightly projecting break, the portico itself being within the building, and nowise differing from a recessed loggia, except that it is not *in antis*, and is crowned by a pediment. Of this kind is the Ionic portico of the East India House, which, instead of being a tetrastyle *in antis*, is converted into a hexastyle by placing six columns in such manner that the end ones come immediately before the antæ or pilasters. The front of the Law Institution, Chancery Lane, may also be called pseudo-prostyle, because, although a loggia *in antis*, it is surmounted by a pediment.

Even in prostyle porticos there is great difference of character merely as regards the degree of projection given to them, independently of other circumstances; some are made to advance a single intercolumn, and others project considerably more. At the risk therefore of appearing to innovate upon the terminology of architecture, we would propose the following terms:—*monoprostyle*, where the portico projects only one intercolumn, as the Ionic hexastyle of St. Pancras church, London; *diprostyle*, where the projection is two intercolumns, as in the porticos of St. Martin's, Charing-cross, and St. George's, Bloomsbury, and so on; by which method the portico of the Pantheon at Rome might be briefly yet distinctly described as a Corinthian octastyle *triprostyle*, that is, a prostyle with eight columns or seven intercolumns in front, and three open intercolumns at its its ends. Another circumstance, which it is highly important to note, is whether a portico be a simple prostyle, or be likewise *polystyle*, that is, whether the columns be merely external, or whether there are additional columns within the portico, as is the case with that of the Pantheon, which may therefore be further described as polystylar. The portico of the Kazan church, St. Petersburg, and those of the Glyptotheca at Munich, and Canova's church at Possagno, are also polystyle. This is likewise the case with the Corinthian octastyle of the Exchange at Glasgow; but scarcely an instance of the kind occurs in London, for the two columns within the portico of the National Gallery hardly entitle it to be so called, and the architectural feature of the Bank which we shall presently notice can hardly be classed as a portico.

Some porticos again may be termed compound prostyles, because, while they project from the building, they also recede within it, as is the case with those of the London Post-Office, University College, and Hanover Chapel, Regent Street; and such an arrangement gives greater effect as well as spaciousness, and prevents the portico from looking like a mere addition to the front of a building. Besides the varieties above enumerated, there are those which are semicircular in plan, of which the transept entrances of St. Paul's furnish very admirable examples; and another occurs in the pseudo-portico or portico-like compartment at the north-west angle of the Bank of England, which, owing to its being likewise recessed, and having columns behind those in front (not arranged concentrically, but placed on the chord to the outer curve), produces an unusually rich and picturesque effect. Beautiful however as the semicircular form is, it becomes unsuitable for such purpose if a portico so shaped cannot be made equal to a hexastyle, or a tetrastyle in antis, that is, have five intercolumns, because if there be only three, either the whole portico must be very narrow in proportion to its height, or the intercolumns so wide that the architrave over them will considerably overhang a line drawn from one column to another, and thereby produce an appearance both of deformity and weakness.

Whatever be the form adopted for a portico, however elegant it may be in all other respects, the character will be neutralised if the background or rear wall be filled with doors and windows. Such is the case with the otherwise noble and classical portico of St. George's, Bloomsbury, which has five arched doors, and as many windows of the same form over them, corresponding with the number of intercolumns of the hexastyle; the consequence of which is that those features are not only quite at variance with the character of the order, but petty in size, and squeezed together, so as to occasion a crowded and confused appearance. The portico of St. Martin's has fewer apertures, there being only three doors and the same number of windows above them, but they are of such horrible design as to be quite inconsistent with the exterior of the portico. Even when such apertures are in the same taste as the rest, they cut up the background to the columns, and give it a character at variance with that professedly aimed at. It is on this account that the pseudo-prostyle or pedimented loggia of the Law Institution looks like the façade of an Ionic temple in antis erected before a modern house-front. The Ionic hexastyle of the College of Physicians is not less faulty, having a door and four windows in the lower part, while above them there is only a single window in the centre, and a niche corresponding with each of the extreme intercolumns. On the contrary, much of the nobleness of character and beauty of design in the porticos of the transepts of St. Paul's, the Post-Office, St. Pancras church, University College, the National Gallery, and the Doric hexastyle in antis of the Corn Exchange arise from the circumstance of their having no windows, and from their doors being made rich and important features. The three doorways within St. Pancras' portico are of most exquisite design, but would have shown themselves to more advantage had they been placed farther back, for the portico being merely a monoprostyle, and not at all recessed, its shallowness causes the doors to be too close to the columns, and thereby prevents their being seen advantageously.

As to windows, unless they can be treated as doorways, and then placed only in the alternate intercolumns, they are such blemishes within any sort of colonnade or portico, that if they cannot be got rid of, both good taste and economy would be better consulted by giving up the portico altogether, and adopting a style of design where windows may be rendered both appropriate and ornamental features. So far however is this from being duly attended to, that frequently no study is bestowed upon such apertures when placed within a portico: a very glaring case of the kind occurs in what we should else pass by as beneath notice, namely, the very paltry Corinthian hexastyle, as it must be termed, forming the front of the Haymarket Theatre, which presents another most offensive solecism in the preposterous width of the lateral intercolumns. So far and so far only does that portico, though of the same order and denomination, resemble the highly beautiful one which graced Carlton House, and which, but for the defect alluded to, was one of the most tasteful and richest specimens that we possessed. It was a Corinthian hexastyle, diprostyle, but of triprostyle proportions, for in order to admit a carriage-drive into the portico (certainly a very great convenience in itself) one intercolumn in each flank was made equal to two of the others and a column, thereby producing a most offensive gap, and causing it to look as if a column had actually been removed in order to allow a carriage to pass. In all similar cases, where much greater width than that afforded by the other intercolumns is required for a carriage-entrance, the best plan would be to substitute an open arch at each end of the portico, by which means, while an equal or even greater breadth of opening might be obtained, it would not show itself to the eye as a positive gap compared with the spaces between the columns in front.* Stafford House, the duke of Sutherland's town residence, offers, among its other defects of design, a striking instance of very faulty and irregular columniation in the upper portico of the north front over that in the basement into which carriages drive: even two more columns might be added to each flank, for at present the entablature of those ends has no support except at its extremities, and consequently offends by the appearance of both poverty and weakness.

Having mentioned porticos which are raised upon a basement, we may further remark that their effect greatly depends upon the manner in which the basement itself is treated. This last-mentioned part should invariably be made to represent as far as possible a solid stylobate, with no windows, and if with only a single doorway the better, as is the case in the east front of St. George's Hospital, Grosvenor Place, where beneath the tetrastyle portico (which is remarkable, and by no means unpleasing in effect on account of its having square pillars instead of columns) there is only a door with a small niche on each side of it. On the contrary, a low basement with small windows beneath a portico has always a mean and crowded appearance, as may be seen in that of the Mansion-House. A similar objection applies to the portico added to the front of the Custom-House after the falling in of the Long-room, and which is certainly no improvement upon the original design. The effect of the portico of the National Gallery, on the contrary, is very much enhanced by its being placed on a solid stylobate more extended than the portico itself, whereby the latter seems to stand firmly on a terrace-like substruction. Besides the valuable expression of firmness and strength thus obtained, the breadth and repose of this lower part give additional effect to the columns, its horizontality contrasting forcibly with their upright lines, and its unbroken surface with the perspective and shadow in the interior of the portico. The only objection criticism can here allege is that the mouldings are rather tame and scanty, and that some further embellishment would not have been amiss. It may be presumed that the architect contemplated the introduction of statues on the piers where the ascent on each side commences; and if such pieces of sculpture should ever be added, they would greatly improve this portion of the façade.

Windows, as already observed, ought to be excluded altogether from a stylobate beneath a portico, but we should not so rigidly object to a series of other openings, whether arches or square-headed apertures between piers, provided they were confined to the centre, as for instance three open arches corresponding with the three middle intercolumns of a hexastyle above them, or with the alternate ones of a more extended colonnade. We conceive too that in similar cases, super-columniation, or rather sub-columniation, might be resorted to with propriety and effect; namely, by converting the insulated piers below into columns of short and massive proportions, so as to produce a distyle in antis, or three open intercolumns beneath the centre ones of a hexastyle, &c.

Although we do not exactly agree with those who would proscribe coupled columns altogether, we certainly protest against them for any kind of pedimented prostyle; such disposition has however most unfortunately been adopted in the principal portico of Buckingham Palace, owing to which what might have been an octastyle is reduced, as regards the number of intercolumns, to a tetrastyle. The intercolumniation also is exceedingly irregular, the intercolumn on each flank being nearly double as wide as those in front, a defect probably occasioned by the necessity of obtaining unusual width there in order to admit the royal state-carriage into the lower portico; for the principal portico, it should be observed, is raised upon another formed by a Grecian Doric order beneath the Corinthian, not applied as above recommended in such case, but continued throughout; whereas had there only been solid piers beneath the angles of the upper portico, the whole would have been in some degree improved, although there would still have remained the defect of diminutive columns and disproportionately wide intercolumns.

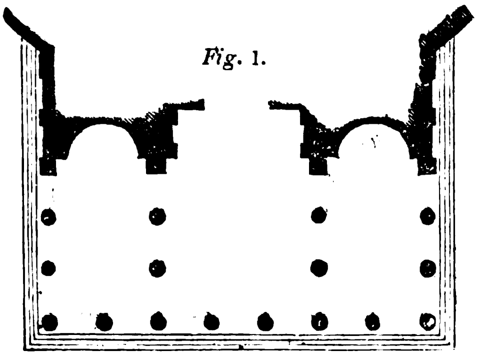
Respecting the mere temple-porticos of the antients, or rather the external arrangement of columns in such edifices, whether confined to the ends or continued along the sides, nothing need be said here, because they offer very little more than slight variations of the same idea, and those are sufficiently explained in the article Civil Architecture. But we shall now briefly pass in review some of the porticos

---

A plan affording an example of the kind may be seen in an article on Porticos and Colonnades in the first volume of the 'Library of the Fine Arts,' which is illustrated with several other original plans.

that most deserve notice on account of their *plan*, to which we shall confine our attention, passing over all other circumstances. We shall not therefore attend to the order of columns employed in them, nor take any account of their dimensions, the plans being drawn not to the same scale, but, for convenience sake, nearly to the same size. We commence with that of the Pantheon at Rome (*Fig.* 1), attached to a circular edifice [PANTHEON], and which, as will instantly be seen, is decidedly different from the usual portico at the end or front of a temple, or from those monoprostyles, or single external line of columns, which constitute the generality of modern porticos.

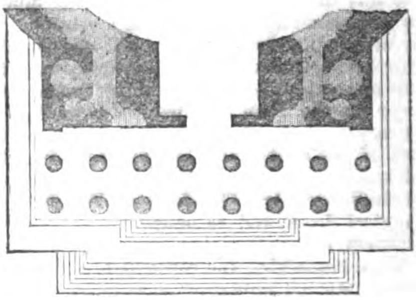
Fig. 1.



Besides being triprostyle, or having three open intercolumns on its flanks, it may be described as polystyle, having columns within, dividing it into three avenues or aisles, the centre one of which is extended by being considerably recessed, a circumstance that adds very greatly to the general effect.

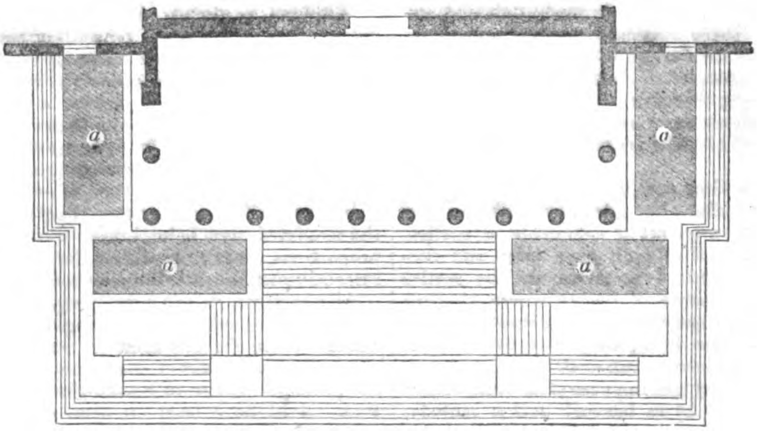
As being, like the preceding, attached to a rotunda, we have selected for the next plan that of the church erected by Canova at Possagno (*Fig.* 2). This also is a polystyle, though altogether different in its arrangement from the other, there being here merely a second range of columns behind those in front, on which account it might be designated a double octastyle.

Fig. 2.



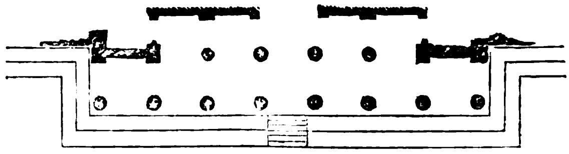
Although there are very few decastyle porticos, it is not merely as an example of one that we here exhibit that of University College (*Fig.* 3), since it might have been such without being at all worthy of notice for its plan, as is the case with the dodecastyle one of the Chamber of Deputies at Paris [PARIS], which is no more than a monoprostyle, or single line of twelve columns, beneath a pediment. That of University College, on the contrary, projects forward very considerably, it being equal to a triprostyle, or a pseudo-triprostyle, with one intercolumn closed up, owing to which it appears internally to be partly recessed, to be carried out two intercolumns, and inwards for the space of one. This example is further remarkable on account of the unusual and highly picturesque arrangement of the steps forming the ascent up to it, which commence below on each side, while above they form a single broad flight, in such manner as to leave screened areas, *a a*, which serve to admit light to the spaces in the basement beneath the portico.

Fig. 3.



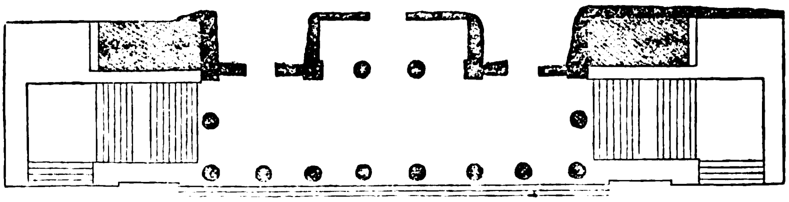
The portico of the Glyptotheca at Munich (*Fig.* 4) [MUNICH] may be described as monoprostyle, recessed, and polystyle, it being compounded of an octastyle advanced only one intercolumn before the rest of the front, and of a tetrastyle in antis behind it, forming five open intercolumns, the extent of the recessed part, by which means not only great richness of columniation, but a picturesque play and contrast are obtained.

Fig. 4.



Like that of University College, the portico of the National Gallery (*Fig.* 5) is pseudo-triprostyle, consequently projects as much as three intercolumns from the building; but, in other respects, differs very materially from it, being only partially recessed in the centre, where are two columns forming a distyle in antis, the only instance among all our London porticos of one with any columns within it. It also differs from the other example altogether in the ar-

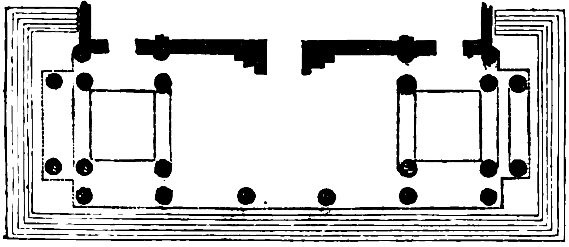
Fig. 5.



rangement of the steps leading up to it, relative to which some remarks have already been made.

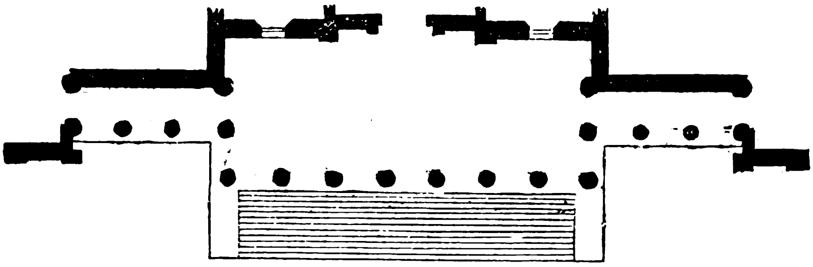
The portico of the Pantheon at Paris (*Fig.* 6) offers a more singular than judicious arrangement, two columns being projected at each end so as to produce a group of three at the external angles, which, although by no means displeasing in the ground-plan, produces an awkward effect in the structure itself or an elevation of it; because, instead of being included beneath the pediment, those columns and their entablature form mere little jutting-out bits, attached to the flanks, and almost suggest the idea of its being originally intended to continue them as lateral colonnades parallel to the hexastyle beneath the pediment (as in the next figure). Though this portico is only hexastyle in front, and has only four columns within, there are eighteen altogether, besides the half and three-quarter columns attached to the wall behind, a number sufficient to have formed an octastyle triprostyle with six inner columns, viz. four disposed as in the portico of the Pantheon (*Fig.* 1), and two forming a pronaos recess for the centre doorway, as in *Fig.* 5. Notwithstanding however the faults already adverted to, and that of its wide intercolumniation, compensated perhaps in some respect by the columns within the portico immediately behind those in front (but which defect might have been obviated by merely making an octastyle within the same space as the present hexastyle), notwithstanding these defects, there is very much to admire in this example, more especially when we compare it with preceding productions of the kind in modern times.

Fig. 6.



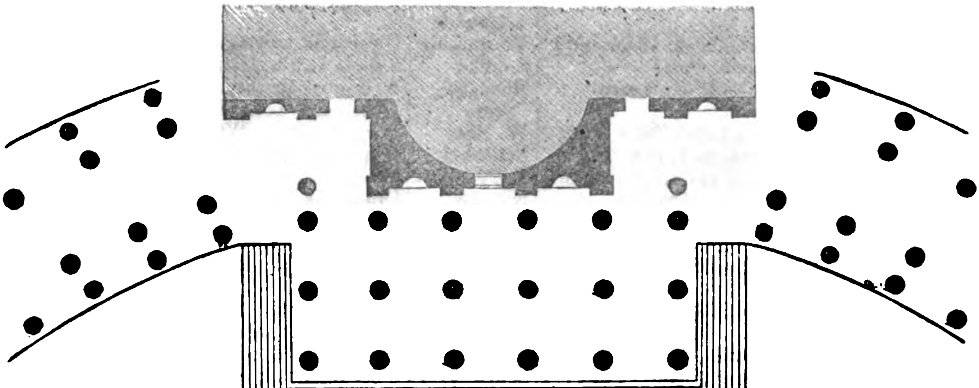
Our next example, which is the portico of the new Fitzwilliam Museum at Cambridge (*Fig.* 7), differs materially from the foregoing one, presenting a richer system of columniation in some respects; for though, technically speaking, no more than a monoprostyle octastyle, it is extended by lateral loggias, three intercolumns in width, and has besides considerable depth within. All that we object to is the substitution of engaged columns for antæ or pilasters, which would not only have been more suitable, but have produced greater variety; nor can we help thinking it would have been very much better to have placed a square pillar instead of a column at the inner angles formed by the junction of the returns of the octastyle and the lateral colonnades; both because these last would have thereby been better defined to the eye, and the meeting entablature would have appeared to be more solidly supported than when, as now, resting upon a circular shaft. Very like this in plan is the portico of the Capitol at Washington, whose centre is also an octastyle, but each of the lateral colonnades has one intercolumn more than those in the Cambridge building. Internally the disposition of the centre portion or octastyle resembles that of the Pantheon, shown in *Fig.* 1.

Fig. 7



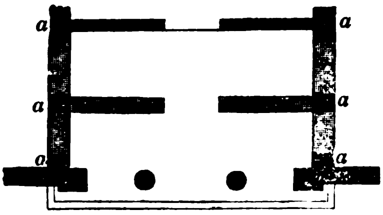
Although only a hexastyle, the portico of the Kazan Cathedral, St. Petersburg, towards the Nevsky Prospect, is an unusually rich example of a polystyle prostyle, and of certain peculiarities of arrangement which will be better understood from the plan itself (*Fig.* 8) than from any verbal explanation. The cut also shows a portion of the sweeping colonnades (in imitation of those by Bernini in the Piazza di San Pietro at Rome), and the mode in which they are connected, or rather not connected with, but merely brought up to the portico itself, which is so awkward and disagreeable as materially to detract from the effect of the whole.

Fig. 8.



On other porticos, which, whatever may be their denomination, or whatever their merits in point of style and execution, consist of no more than a single range of columns in front, we cannot stop to make any remarks, although several of them would furnish abundant matter for criticism, and among others that of Covent Garden Theatre, which, though generally received as such, is anything but a classical composition, the doorways being mean in the extreme, mere holes in the wall, and the windows above them destroying all architectural repose and breadth of effect. We cannot however pass over Mr. Gandy Deering's small Doric distyle in antis, in the front of the building originally erected for the Pimlico Proprietary School in Ebury Street (*Fig.* 9), since it claims to be brought forward by us as a solitary example of a portico with an inner screen carried up half way behind the columns, and with lateral openings at the ends of the portico between small antæ, *a*, *a*, &c., descending as low as the top of the screen, and two of them resting on its exterior ends. The idea is a valuable one, and admits of almost endless diversity and new combinations.

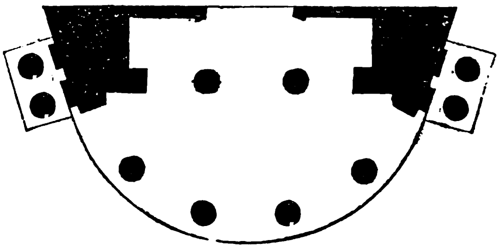
Fig. 9.



The only other example we shall offer is that of semicircular, or rather segmental loggia, forming the northwest angle of the Bank of England (*Fig.* 10), the most tasteful and picturesque piece of design that Sir J. Soane ever produced.

The effect of the inner columns, the contrast they afford to the others, their shafts being plain, while the rest are all fluted, the varied perspective appearance accordingly as the spectator shifts his station, and the great play of light and shade, all render this little bit quite an architectural study.

Fig. 10.



The annexed table may be found useful both as facilitating comparison and from its containing several additional examples, besides supplying various further particulars in regard to some of those which are represented in the plans above given.

Table of Porticos.

Class.	Order.	Building.	Architect.	Remarks.
Dodecastyle	Corinth.	Chamber of Deputies, Paris	Poyet	Monoprostyle, sculptured pediment.
Decastyle	„	University College, London	Wilkins	Hyper-diprostyle, recessed. Height of columns 30 feet.
Octastyle	„	Pantheon, Rome	. . . .	Hyper-triprostyle. Polystyle and recessed.
„	„	National Gallery, London	Wilkins	Hyper-diprostyle, with distyle in antis, recess within.
	„	Fitzwilliam Museum, Cambridge	Basevi	Monoprostyle, recessed, and with order continued laterally, forming three intercolumns on each side.
„	„	Victoria Rooms, Bristol	Dyer	Unequal diprostyle, recessed, five intercolumns.
„	„	Exchange, Glasgow	Hamilton	Diprostyle, with two inner columns corresponding with second and seventh of the octastyle.
„	„	Buckingham Palace	Nash	Columns fluted, their height 26 feet.
Octastyle-Peripteral	„	Birmingham Town-hall	Hansom & Welsh	Columns 36 feet high. Side elevations of twelve intercolumns on flanks.
„	„	La Madeleine, Paris	Huvé	See PARIS.
„	„	Girard College, Philadelphia	Walter	Columns 55 feet high; marble.
„	Doric	The Walhalla, Bavaria	Klenze	
Octastyle	Ionic	Glyptotheca, Munich	Klenze	Monoprostyle, polystyle, recessed, tetrastyle in antis.
„	„	Great Theatre, Petersburg	Thomond	Monoprostyle.
„	Doric	Church at Possagno	Canova	Diprostyle, polystyle, double octastyle.
„	„	Manège, Petersburg	Quarenghi	Monoprostyle, polystyle, recessed.
„	„	Royal Institution, Edinburgh		
Hexastyle	Corinth.	St. Martin's, Charing-cross	Gibbs	Diprostyle, height of columns 34 feet.
„	„	St. George's, Bloomsbury	Hawksmore	Diprostyle, five arched doors, and five arched windows above them.
„	„	St. George's, Hanover Sq.	J. James	Monoprostyle.
„	„	Law Courts, Dublin	Cooley and Gandon	Monoprostyle.
„	„	Kazan Church, Petersburg	Voronikhin	Diprostyle, polystyle, a triple hexastyle.
„	„	Pantheon, Paris	Soufflot	Reliefs within portico, height of columns 62 feet.
„	„	Madre di Iddio, Turin	Buonsignore	A diprostyle, attached to a rotunda. Two inner columns behind the penultimate ones in front.
„	„	Custom-house, New York	W. Ross	Monoprostyle. White marble; columns 32 feet high.
„	„	St. Nicholas's, Potsdam	Schinkel	Hyper-monoprostyle.
„	Ionic	Bethlem Hospital, London	Lewis	Monoprostyle; height of columns 36 feet.
„	„	Post-Office, London	Smirke	Diprostyle, recessed, columns 37 feet high.
„	„	Theatre, Berlin	Schinkel	Monoprostyle, flight of steps in front.
„	„	East India House, London	Jupp	Pseudo-prostyle; height of columns 30 feet.
„	„	St. Pancras' Church, London	Messrs. Inwood	Monoprostyle; florid Ionic; columns 36 feet high.
„	„	Royal Institution, Manchester	C. Barry	Monoprostyle. Order continued laterally, forming loggias of three intercolumns on each side of prostyle.
„	„	Post-Office, Dublin	F. Johnston	Monoprostyle, columns 36 feet high, fluted.
„	„	Raadhus, Copenhagen	Hansen	Monoprostyle; deep recess in centre with steps.
„	Doric	Colosseum, London	D. Burton	A monoprostyle attached to a polygon.
„	„	Hunterian Museum, Glasgow	. . . .	Monoprostyle, recessed, with a distyle in antis.
„	„	County-hall, Chester	T. Harrison	Monoprostyle, polystyle, recessed. A double hexastyle.
„	„	Wacht-Gebaude, Berlin	Schinkel	Monoprostyle, recessed as a tetrastyle in antis.
Pseudo-hexastyle	Corinth.	Front of Roman Catholic Chapel, Finsbury Circus	. . . .	Four pilasters and two columns beneath a pediment, or five intercolumns.

PORTLAND (Isle). [DORSETSHIRE.]

PORTLAND, DUKE OF. [PITT.]

PORTLAND (America). [MAINE.]

PORTLAND OOLITE, a term in geology, synonymous with epioolite of Brongniart, and upper oolite of some English geologists.

PORTLAND STONE. [DORSETSHIRE.]

PORTLAND VASE. The beautiful specimen of antient art known by this name, but formerly bearing the appellation of the Barberini Vase, is one of the choicest treasures deposited in the British Museum. The time of its production is now unknown; but it is presumed to be the work of a Grecian artist. The first information we have respecting it is, that about the middle of the sixteenth century the vase was found enclosed in a marble sarcophagus, within a sepulchral chamber, under the mount called the *Monte del Grano*, about two miles and a half from Rome on the road leading to Frascati. This sepulchral chamber appears to have been the tomb of the emperor Alexander Severus and of his mother Julia Mammæa; and the vase was probably a cinerary urn belonging to the sepulchre. Bartoli, in his work on Roman and Etruscan sepulchres (*Gli Antichi Sepolcri*, 1704), has given a sectional representation of the Monte del Grano, with the hollow sepulchre within, and the spot in which the sarcophagus was found lying. The elegance of form and the admirable workmanship of the vase procured for it, as well as for the sarcophagus which enclosed it, a place in the palace of the Barberini family at Rome, where it remained more than two centuries; after which it became the property of Sir William Hamilton, from whom it passed to the Duchess of Portland. At length, in the year 1810, it was deposited in the British Museum by the Duke of Portland, and placed on an octagonal table in the middle of the small ante-room (No. 9) at the head of the stairs leading from the gallery of antiquities.

This vase was said by Montfaucon to be formed of a precious stone; but subsequent examination has shown the material to be dark blue glass, relieved by figures and devices in white enamel. It is about ten inches in height, and beautifully curved from the top downwards; the diameter at the top being about three inches and a half; at the neck or smallest part, two inches; at the largest part (mid-height), seven inches; and at the bottom, five inches; with two handles, one on each side. The blue tint of the glass is rich and beautiful, and is rendered still more so by the contrast of the delicate white enamel of which the figures are formed. These figures are seven in number, three men, three women, and a winged Cupid; but the story or scene represented has never been satisfactorily explained, although many attempts at explanation have been made. Dr. King (*Archæologia*, vol. viii.) endeavours to show, by a somewhat forced construction, that the scene had a mythological relation to the birth and acts of the emperor Alexander Severus; and other theories of a similar kind have been advanced. The figures however, whatever may be their import, are placed in the following order: on entering the ante-room one of the handles is first seen, having beneath it a wild-looking head, with long hair and beard; near the handle (to the right) is a male figure standing under a kind of porch, and offering his extended arm to a female seated on the ground, over whose head bends the branch of a tree: a winged boy is hovering over these two figures; and to the right is a man leaning his elbow, in an easy attitude, on his knee, the foot being raised on a stone, and his chin resting on his hand. We then come to the second handle, which has a head under it similar to that on the opposite side; near this handle is a man seated on a stone, and looking at a female figure reclining in an easy and elegant attitude, with an inverted torch in her left hand, and the right passing over her head; the branch of a tree bends over her, and at her left hand is another male figure, who is looking towards her, and holding a staff in his left hand. These figures are about five inches in height, and are modelled or moulded with minute accuracy. Being different in colour and in opacity from the glass on which they are laid, they must have been fashioned before being fixed on the vase; yet the union has been so complete that no joint can be seen between them, and the minute details of the figures have not been in the slightest degree injured by the heat which in all probability was necessary for the process of cementation. At the bottom of the vase is an enamelled head and bust of a figure whose hand is elevated towards the mouth, and who has a fine Grecian outline of face. As this part of the vase cannot be seen in its present position, a cast of it is attached to the stand on which the vase is placed. Dr. King was of opinion that this head was part of a larger work, and was cemented on the vase by a process different from that employed on the other parts.

A mould of the vase was made by Pechler, the gem engraver, while it was in the possession of the Barberini family; and from this mould a certain number of casts in plaster of Paris were taken by Mr. Tassie, who afterwards destroyed the mould. Mr. Wedgwood made a small number of copies of this vase, which were sold at about twenty-five guineas each, and which were distinguished for the admirable skill displayed in their production. The moulds employed for these copies are, we believe, still in existence; but the extreme difficulty of the manufacture renders their production, as a commercial speculation, unprofitable.

PORTO BELLO. [PUERTO BELLO.]

PORTPATRICK. [WIGTONSHIRE.]

PORTO. [OPORTO.]

PORTO SANTO. [MADEIRA.]

PORTA, BACCIO DELLA. [BACCIO.]

PORTRAIT (*Portrait*, French; *Ritratto*, Italian; *Bildniss*, German; *Imago*, Latin; *εἰκών*, Greek). A portrait, strictly speaking, signifies the likeness of anything whatever, whether animate or inanimate, either drawn or coloured upon a flat surface: in a more restricted sense it signifies a drawing or a painting representing the likeness of any particular individual; but it is also frequently applied to the pictures of animals.

Portrait, says Lord Orford, is the only true historical painting. Its uses are manifest; it administers to the affections, it preserves to the world the features of those who, for their services, have merited the gratitude of mankind, and of those who have been in any way remarkable for their own actions or through their position in society; and in a simply historical point of view, it illustrates the costume and habits of past ages.

Portraiture seems to be almost as antient as the art of painting itself; indeed, according to the romantic legend told by Pliny (*Hist. Nat.*, xxxv. 12, 43), it was in Greece the origin of the imitative arts; an enamoured Corinthian maid traced the profile of her lover around his shadow cast by a lamp upon the wall.

The most antient portraits extant, if they can be termed such, are those which have been found in the cases of mummies: there is a singularly fine specimen of these preserved in the Egyptian museum of the Louvre in Paris; and there is also one of mean execution in the British Museum.

It was a custom among the antients, in very early times, for warriors to have their portraits painted upon their shields, called by the Romans *imagines clipeorum*, or *imagines clipeatæ*, and these shields were frequently dedicated in the temples in honour of their owners when deceased, or placed by victors as trophies (clipei votivi). The portraits were most probably painted in wax, but that they were well executed is very doubtful. (Pliny, xxxv. 3.)

Among the Romans, in the time of the republic, the possession of the portraits of their ancestors (*imagines majorum*) was a proof of nobility, for by the *jus imaginum* none were permitted to make portraits of themselves except those who had themselves or whose ancestors had borne some curule magistracy; and Roman families were accustomed to boast of their *fumosæ imagines* as a proof of their antient nobility. (Cic., *In Pisonem*, 1.) These portraits or images, which were of wax, were preserved with great care by their posterity, and were only brought out upon great occasions or carried before them in funeral processions. (Pliny, xxxv. 2.) They were probably painted busts, for the art of casting with wax in plaster moulds taken from the life was, according to Pliny (xxxv. 12, 44), invented as early as the time of Alexander, by Lysistratus the brother of Lysippus. It seems that the Romans were also sometimes in the habit of prefixing the portraits of authors to their works. Martial mentions one of Virgil (xiv. 186).

The most antient portrait-painter of extraordinary merit on record was apparently Dionysius of Colophon: he is praised by Aristotle (*Poet.*, 2) for the fidelity of his paintings; and from what Plutarch says (*Timol.*, 36) of the high finish of his works, we may perhaps term him the Holbein of antiquity: he flourished, as nearly as can be ascertained, shortly after the time of Polygnotus and Phidias, about 430 B.C.

The most famous portrait-painter among the antients was Apelles: he enjoyed the exclusive privilege of painting the portraits of Alexander: one of his most celebrated pictures was a portrait of that monarch as Jupiter, called the 'Alexander Ceraunophoros,' for which, according to the incredible account of Pliny (xxxv. 10, 36), he received twenty talents of gold (upwards of 50,000*l.* sterling); so large a sum, that it was measured to the painter, not counted ('mensura, non numero'). Most of the pictures of Apelles were portraits in an extended sense, yet it is doubtful whether before the time of the Roman emperors there was a distinct class of painters who confined themselves to portraits ('imaginum pictores:' Pliny, xxxv. 11, 40). Even in the great days of Italian art there was not a distinct class of portrait painters as in the present times; and it is an incontestable fact, that although upon the whole the number of good portrait-painters has very much increased, still portrait-painting itself has not improved since such has become the practice.

The success of a portrait depends upon the sitter as well as upon the painter, and it may be spoiled by the bad taste of the one or the other. Excellence in portraiture consists in placing every feature in its proper place, in a correctness of modelling, a judicious arrangement of light and shade suited to the complexion of the subject, and in tasteful attire and an unaffected and simple attitude; the former are within the province of the painter, the latter in that of the sitter. Much of the character may be shown by the posture, and the painter should adopt that which appears most natural to his sitter, for the habits of nature must be distinguished from those of fashion; no defect is more striking in a portrait than a forced and affected attitude.

In every portrait the countenance of the person represented should constitute the picture; all accessories must be kept subordinate to the principal object, and should not engage the attention except when expressly examined, for they are the mere adjuncts necessary to indicate the character, rank, or nation of the original. Upon these principles a good portrait must be a good picture, for the beauty of a picture consists in the harmony of the whole in composition, colour, and execution; and when every part has received no more of the painter's attention than its local importance requires, a picture cannot in any particular deviate from the truth, simplicity, and unity of nature. Fancy costumes are injurious to portraits as portraits, for a general resemblance being the principal object of portraiture, the subject should be clothed as usual, and the more simple the attire, the more prominent and consequently the more important will be the head, which is the principal object. Whatever deviations are allowed from this principle, although the picture may perhaps gain in pictorial effect, it must lose as a portrait. A mere insipid transcript of the features, and an equally minute attention to the detail of the accessories, are a degradation of portrait. There is no other difference between historical painting and portrait painting than that portrait exacts a stricter attention to the individual character, and consequently requires a more careful execution of the head, but the draperies and accessories should be equally bold and free as in historical painting. Large canvasses, and what are termed full-lengths, are ill suited to portrait, and the latter are seldom successful even under the most able hands. How often we see a great field of canvass, where the head is a mere speck, and is generally lost in the mass of accessories, of trees, columns, or draperies; these are pictures of robes, not of men, and are only tolerable as state portraits, when the insignia of rank or office are more important than the individuals. Such should be termed Iconics (*εἰκονικοί*) rather than portraits. [Panaenus.]

Expression is perhaps the most important study in portrait. To represent the true character of an individual, the countenance should be painted in repose, when no particular sentiment or passion predominates; for an otherwise good picture may be rendered a very bad portrait through the injudicious adoption of some transitory expression, or the introduction of a smile put on for the occasion, when perhaps the mouth is smiling whilst the eyes are languid and fatigued. The expression may be also materially injured by exaggerating the local tints, which in most cases has the effect of changing the complexion, and the particular expression of every individual depends upon the complexion as well as upon the relative proportions of the features. It is by accurately giving these proportions that what is called a striking likeness is produced, and this may be accomplished without entering into any minute detail of the parts; the features are indicated rather than expressed: this is a principle of historical painting, but is a style only fit for the portraits of public characters, or such as are to be placed in spacious localities, and must be viewed at a distance.

Such portraits, when even of only tolerable resemblance, are generally pronounced to be striking likenesses, especially by those who have but an imperfect knowledge of the persons represented; for they are themselves unacquainted with any more of the physiognomy of the originals than they see expressed in the pictures. These portraits however lose their resemblance either upon close inspection or upon a prolonged view.

The most successful painters of portrait in modern times have been Lionardo da Vinci, Raffaelle, Sebastian del Piombo, Giorgione, Paris Bordone, Titian, Velasquez, Holbein, Hals, Rembrandt, and Vandyck; and the following pictures are amongst the finest specimens of portrait painting extant:—his own portrait by Lionardo da Vinci, in the portrait gallery at Forence; Andrea Doria, by Sebastian del Piombo, in the Palazzo Doria at Rome; the head of Guido by Simone Cantarini, in the Academy at Bologna; Titian and Aretin, by Titian, in the royal collection at Windsor; Pope Innocent X., by Velasquez, in the Palazzo Doria at Rome; the Meyer Family, by Holbein, in the gallery at Dresden; and the head of Gevartius, by Vandyck, in the National Gallery in London.

Of the portrait painters of more recent times, Mengs, Reynolds, Gainsborough, David, Gerard, and Lawrence have enjoyed the greatest celebrity.

PORTSMOUTH, a corporate town in Hampshire, on the coast of the English Channel, and the principal station of the English navy; it is 66 miles in a direct line south-west of St. Paul's, London, or 73 from the General Post-Office by the mail-road through Kingston, Guildford, Godalming, and Petersfield; in 50° 47′ N. lat. and 1° 7′ W. long.

The harbour of Portsmouth is formed by the western end of an inlet of the British Channel, which, with its various creeks, extends nearly sixteen miles from west to east, from Fareham, in Hampshire, to Fishbourn, a village close to Chichester in Sussex; and about four miles, on an average, from the open sea, inland. Two large alluvial islands, Portsea island on the west and Hayling island on the east, divide this inlet into three parts: the westernmost and smallest part forms Portsmouth harbour, between Portsea island and the main; the middle portion, between Portsea island and Hayling island, forms Langston harbour; and the eastern part, between Hayling island and the main, is divided by a smaller island (Thorney Island) into Emsworth channel and Chichester harbour. Each of these divisions presents, when the tide is up, a noble sheet of water; but when the tide is out, they are chiefly occupied by mud-banks, separated by channels of greater or less width. The greater depth of the channel, the narrowness of the entrance, and the consequent facility of defending it, render Portsmouth harbour by far the best of the three. The roadstead between the mouth of Portsmouth harbour and the Isle of Wight forms an anchorage, part of which is well known under the name of Spithead. Adjacent to Spithead, on the coast of the Isle of Wight, near the eastern extremity of the island, is the bay of St. Helen's, a place of rendezvous for the navy; and near the coast of the Isle of Wight, between Cowes and Ryde, is the Motherbank, an anchorage for smaller vessels.

The excellence of the port attracted the notice of the Romans, who established a station at Porchester on its northern shore; this was probably the Portus Adurni, or perhaps the 'Portus Magnus' of the Notitia; and the element of the Roman name Port-us has been transmitted directly or mediately to the modern Port-chester, Portsea (Port's-ey, 'the island of the port'), Ports-mouth, Ports-down, and Gos-port. The decline of Port-chester, where there are still some Roman remains [Hampshire], is ascribed to the retiring of the sea, in consequence of which the inhabitants removed and built Portsmouth, which is first noticed in the 'Saxon Chronicle' on occasion of the landing (A.D. 501) of a body of Saxons, allies of Cerdic, founder of the West-Saxon kingdom. The leader of this body is said to have been called Porta, and some have supposed the name of Portsmouth to have been derived from this circumstance; but the etymology given above appears much more probable. [Hampshire.]

Portsmouth was a place of importance in the time of Henry I. Robert of Normandie landed here with a strong force (A.D. 1101), when he came to dispute the crown with Henry [Henry I.]; and the empress Maud, with her supporter the Earl of Gloucester, landed here (A.D. 1139 or 1140) to dispute the crown with Stephen. Richard I. granted to the town a charter, with the privilege of a weekly market and a yearly fair of fifteen days; and from some antient records it has lately been ascertained that there was a naval station at Portsmouth in the reign of John. In the time of Richard II. (A.D. 1377), Portsmouth was burned by the

French. Edward IV. and Richard III. secured it by fortifications; which were completed by Henry VII. In the reign of Henry VIII., it became the principal if not the only station of the English navy, and in A.D. 1544 an indecisive engagement between the English and French fleets took place off Spithead. In the time of Charles I. (A.D. 1628), the duke of Buckingham, who had come down to hasten the equipment of the armament for the relief of Rochelle, was assassinated here. In the great civil war, the town was garrisoned for the parliament. The marriage of Charles II. with Catherine of Braganza was celebrated here (A.D. 1662). Since the time of Henry VIII. the fortifications have been so far extended (especially in the reigns of Charles II., William III., and George III.) as to be now impregnable. It is said to require a garrison of 13,500 men to man the works and the forts, in case of a siege. The moats, which are wide and deep, can be filled with water from the sea.

The town of Portsmouth is situated at the south-western extremity of Portsea island, and just at the entrance of the harbour. It is enclosed by fortifications forming a semicircle to landward, and has an area of 110 acres; it contained, in 1831, 1195 houses (beside 6 building and 40 uninhabited), inhabited by 1627 families; the population was 8083. The streets, with the exception of High-street, are narrow, and consist of houses of inferior appearance. There are some substantial houses in High-street, and on the Grand Parade, which is at the western end of High-street. North of Portsmouth is Portsea, considerably larger than Portsmouth, extending along the harbour, and containing the dock-yard and the principal establishments connected with it. Portsea, like Portsmouth, is strongly fortified, and its defences are so united with those of Portsmouth, that the two towns may be considered as comprehended in the circuit of one fortress. The streets of Portsmouth and Portsea are well lighted and paved. Outside the fortifications of these two towns are extensive suburbs, as Southsea on the east of Portsmouth, Landport adjacent to Portsea, and Mile End and Kingston rather more remote. Some of the houses in the suburbs are handsome, especially those on Southsea Common; others, though neatly and regularly built, are smaller and of inferior description. There are some groups of habitations less connected with Portsmouth. All these suburbs are in the parish of Portsea, which comprehends the whole of Portsea island, except the town of Portsmouth, some extra-parochial districts, chiefly belonging to government, on the east side, on the shore of Langston harbour, formerly occupied by some salterns, and the northern extremity of the island, which is in Wimmering parish.

The mouth of Portsmouth harbour is about two miles wide between Fort Monkton and Southsea Castle, two strong forts erected to command the approach. Within these points the passage narrows to about a furlong, at what may be considered the true entrance into the harbour: within this entrance the harbour widens to half a mile between the dock-yard at Portsea and the town of Gosport on the opposite side; farther in, it expands to the width of three miles, and contains the three small low islands—Pewit Island, Horsea Island, and Whale Island. There is sufficient depth of water for a first-rate ship to enter the harbour at almost any time of the tide. About a mile and a half from the entrance the main channel branches into three arms, leading respectively to Fareham, Porchester, and Portsbridge and the northern end of Portsea Island. The dockyard is the largest in the kingdom, covering from 115 to 120 acres; it has a wharf-wall along the harbour of nearly three quarters of a mile, and is enclosed on the land side by a wall fourteen feet high, which completely separates it from the town. It includes a ropehouse, anchor-wharfs, an anchor-forge, a copper-sheathing foundry and mills; block, mast, sail and rigging, and other store houses; a grand basin, in which vessels are received with all their standing and running rigging to be repaired; building-slips, docks for repairing—in a word, all that is requisite for the construction, equipment, armament, and repair of vessels. There are also residences for the port admiral, the admiral superintendant and the other officers of the yard, a chapel, a school for Naval Architecture, and other buildings. The block-machinery, invented by Mr. Mark Joambard Brunel, is an admirable manifestation of mechanical skill; it is impelled by steam. There are forty-four machines which are arranged in three sets for blocks of different sizes. They take the rough timber, cut it up, shape and bore it, and carry the process through to the completion of the blocks. The machinery is capable of producing 1400 blocks daily, and supplies the whole of the British Navy. The number of men employed in the dockyard, in time of war, has amounted to 4000 and even 5000. The dockyard has three times been seriously injured by fire: in 1760, from the effect of lightning; in 1770, from an unascertained cause; and in 1776, from the attempt of an incendiary, John Aitkin, otherwise 'Jack the painter,' who was executed for the crime at the dock-gates, on a gallows 64 feet high, and afterwards hung in chains on the beach, on the west side of the entrance of the harbour. Adjacent to the dock-yard is the spacious and well furnished Gun-wharf and its connected buildings. It is the grand depôt for cannons, shot, and every description of ordnance stores.

The parish church of St. Thomas, Portsmouth, is a spacious building, including some antient portions, but mingled with additions of various later periods. The tower is 120 feet high, and forms a good mark for seamen, but the architecture is heavy and tasteless. It is surmounted by a cupola and lantern; the whole is crowned by the model of a ship, which serves as a vane. The garrison-chapel is on the Grand Parade; it is an antient structure which belonged to the hospital of 'Domus Dei' (House of God), repaired and fitted up for the officers and soldiers of the garrison. The parish church of St. Mary, Portsea, is in the suburb of Kingston; it is an antient building surrounded by one of the largest burial-grounds in the kingdom. The chapels of St. George and St. John, in Portsea, are commodious edifices of little architectural beauty, erected in the latter half of the last century; the new church of St. Paul, Southsea, capable of accommodating 1900 persons, is a quadrangular building, in the perpendicular style of Gothic architecture, with four low turrets at the angles; the church of All Saints, Mile End, is of similar architecture, with a handsome western front, crowned with a bell-turret, and will accommodate more than 1700 persons. A new Gothic church with a tower has been built at Portsmouth, capable of holding above 1200 persons, and another of very pleasing architecture is in course of erection in Portsea: making altogether nine places of worship of the establishment. Those of the Protestant Dissenters are yet more numerous; and there are a Roman Catholic chapel and a Jews' synagogue.

Among the other public buildings are the town-hall with a covered market-place underneath, in High Street; the governor's house, on the Grand Parade, originally part of the hospital of Domus Dei, but so much altered as to retain little of its monastic appearance; the residence of the lieutenant-governor; the theatre; the building of the Philosophical Society; and a national school house, with elegant concert, assembly, and card rooms above: all these are in Portsmouth. The ramparts are planted with trees, and form an agreeable promenade; the saluting battery, at the end of the Parade, commands a fine view of the anchorage of Spithead and the Isle of Wight. On the London road, about two miles from the town, extending from the road to the harbour, is an extensive cemetery, laid out and planted with trees, and furnished with a chapel for the burial service, and an office for the officiating minister.

The population of Portsmouth has been given: that of Portsea, in 1831, was 42,306; of Portsmouth and Portsea together, 50,389. (*Pop. Returns.*) Of the inhabitants of Portsea, 14,874 were in the town, 23,325 in the suburbs. (*Rep. of Municip. Corpor. Commissioners.*) The area of Portsea parish is given in the same Return at 4980 acres; the number of inhabited houses at 8215, beside 57 building and 327 uninhabited; and the number of families at 9767. The trade of the place, which is considerable at all times, but especially in time of war, depends much upon the expenditure connected with or caused by the naval station and dockyard, and is of a very miscellaneous character.

The port extends from the town of Emsworth, on Emsworth channel on the east, to the entrance of Southampton Water on the west; and includes Portsmouth and Langston harbours, Emsworth channel, and the roadsteads of Spithead and the bay of St. Helen's between Portsmouth and the Isle of Wight. There is considerable coasting and foreign trade carried on. The Portsmouth and Arun Canal was originally carried nearly across Portsea Island (entering it from Langston harbour, across which the canal boats are towed by steam) to its terminus in a capacious basin at Landport;

but the creek at Portsbridge has, since the last peace, been rendered navigable. Barges have thus direct access to the docks and wharfs of the harbour and the towns surrounding it, and the cut being now useless, the basin has been filled up and built upon. There is a considerable import of coal (it has increased thirty per cent. in the last ten years), and also of cattle, from the Isle of Wight and from the west of England. Fifty thousand sheep have been brought in in a single year. Corn and provisions are brought in from Ireland, eggs from France, timber from the Baltic, and wine is imported direct from the Continent. Several steam-vessels visit the port, some of which go and return several times in the day; and there are others which touch here in their passage. Communication is thus kept up with the Isle of Wight, Southampton, Plymouth, and Hâvre. A considerable part of the land round the town is laid out in market-gardens, from which the town is supplied with excellent vegetables. Tuesday, Thursday, and Saturday are market-days. There is a yearly fair of fifteen days from the 10th of July; and a holyday fair, held on Portsdown Hill, at the close of Portsmouth fair, is much frequented.

The corporation of Portsmouth is said to have been established by Henry I., but the earliest known charter is of Richard I.; many subsequent charters were granted. The borough limits formerly included the parish and town of Portsmouth, the town of Portsea, and a considerable part of the parish of Portsea, extending along the harbour, the whole of which was in the jurisdiction of the corporation. By the Boundary Act the limits were extended, for parliamentary purposes, so as to include the whole parish of Portsea; and by the Municipal Reform Act the parliamentary limits thus extended were adopted for municipal purposes. The enlarged borough is divided into six wards. The number of aldermen was fixed, by the Municipal Reform Act, at 14; the number of councillors at 42. Quarter-sessions for the borough are held. There is a Court of Record, having jurisdiction in all personal actions, and petty-sessions are held three times in the week. The prison is not well situated, nor is it sufficient for the proper classification of the prisoners. There is neither chapel nor chaplain. The place is kept clean, but the discipline is considered too lax. (*Inspectors of Prisons' Third Report.*) The average number of prisoners is 50. Portsmouth first returned members to parliament 23 Edward I.; the number of voters, before the Reform Act, was very small, but is now considerable. The number on the register in 1835-36 was 1439.

The living of Portsmouth is a vicarage, of the clear yearly value of 555*l.*, with a glebe-house. The living of Portsea is also a vicarage, of the clear yearly value of 696*l.*, with a glebe-house. The perpetual curacies of the chapels are, in clear yearly value, as follows: St. George's, 45*l.*, with a glebe-house; St. John's, 141*l.*, with a glebe-house; St. Paul's, Southsea, 310*l.*; and All Saints, Mile End, 160*l.* The vicar of Portsea is patron of these, except St. John's, to which the proprietors of pews present.

There were, in 1833, in the parishes of Portsmouth and Portsea, an infant school, with 40 children, held in Portsea workhouse; a grammar school for 20 free scholars; a large school, called 'The Beneficial Society School,' with from 260 to 300 boys; 'The Portsea Institution,' for 110 girls; two Lancasterian schools, with 250 boys and 112 girls; two national schools, with 409 boys and 160 girls; 'the seamen's school,' with 210 boys and 80 girls; a 'national school of industry,' with 40 boys and 40 girls; two workhouse schools, with 70 boys and 60 girls; and four other schools, wholly or partly supported by subscription, with 271 children of both sexes. There was a proprietary school, with 100 boys, and there were about two hundred and seventy day or boarding and day schools, most of them of a very humble description. There were Returns of the number of scholars from two hundred and seventeen of these schools, which contained 1243 boys, 475 girls, and 2657 children of sex not distinguished. There were, at the same time, twenty-six Sunday-schools, with 4629 scholars of both sexes. Some of the charity and most of the Sunday-schools have lending libraries attached. There are a Portsmouth and Portsea Literary and Philosophical Society, with a tolerably extensive museum; an institution, called 'The Hampshire Literary Society,' with a valuable collection of books; and a Mechanics' Institution.

Beside the fortifications of the two towns of Portsmouth and Portsea, the island of Portsea has strong defences. On the southern extremity is Southsea Castle, built by Henry VIII., mounted with heavy cannon, and commanding the approach to the harbour from the eastward; and on the eastern point, at the entrance to Langston harbour, which it commands, is Fort Cumberland, a large fort, erected in 1746, and mounted with 100 heavy guns. The entrance to the island from the north is defended by lines, carried along the bank of the channel which separates the island from the mainland, and by other works at Hilsea, four miles from Portsmouth. Fort Monkton, which commands the approach to the harbour from the west, corresponding in situation to Southsea Castle on the east, is not on Portsea Island, nor are the fortifications of the town of Gosport, on the shore of the harbour opposite Portsmouth, but both these may be considered as part of the system of defences which protect Portsmouth harbour.

PORTUGAL, THE KINGDOM OF, is the most westerly kingdom of Europe. It forms part of the Spanish peninsula, and is not divided from Spain by any well defined natural boundaries. All the great rivers of Portugal, the Minho, the Douro, the Tagus, and the Guadiana, have their sources in Spain, and belong to Portugal only in the lower part of their basins. The Mondego is the only considerable river which has its sources and its whole course within the limits of Portugal. Portugal is bounded on the north by the Spanish province of Galicia; on the east by the Spanish provinces of Leon, Estremadura, and Andalusia; and on the south and west by the ocean. Its greatest length is about 350 miles from north to south, and its breadth varies from 90 to 125 miles. Its area is reckoned at about 37,900 square miles, or about 10,000 square miles more than the area of Ireland. It has a coast-line of about 500 miles, of which about 400 miles face the west.

Mountains, &c.—The country is intersected by several ridges which are a continuation of the chains which cross Spain from east to west. In the north, the Serra de Maraon is a continuation of the mountains of Astorga, which divide the waters of the Minho from those of the Douro. It enters Portugal north of Braganza, and covers the greatest part of the province of Tras os Montes and part of that of Entre Douro e Minho. South of the Douro is the Serra de Alcoba, which divides the basin of the Douro from that of the Mondego; and south of the Mondego is the Serra de Estrella, a continuation of the Sierra de Gata, which is the western part of the great central ridge of Castile that divides the waters of the Douro from those of the Tagus and the Mondego. The Serra do Junto, which is a continuation of the Estrella, runs nearly parallel to the coast, and terminates in the high promontory called Cabo da Roca, the most western point of the continent of Europe. The highest summits of the Serra de Estrella are between 6000 and 6500 feet above the sea. South of the Tagus, the Sierra de San Pedro, a continuation of the Montanas de Toledo, enters Portugal near Portalegre, and divides the basin of the Tagus from that of the Guadiana. Farther south is the Serra de Monchique, which may be called a continuation of the Sierra Morena, being separated from it only by the course of the Guadiana. The great chains of the Portuguese mountains have a general inclination from north-east to south-west, and they throw off numerous offsets, which cover a great part of the country. Between these chains are the three great basins of the Douro, Mondego, and Tagus. [BEIRA; ESTREMADURA (Portuguese).] South of the Tagus is the plain of Alemtejo, the largest in Portugal, which is divided on the south-east by the mountains of Portalegre, Estremoz, and Evora from the basin of the Guadiana, which, differing in this respect from the other great rivers of Portugal, has a general direction from north to south, and belongs, even in its lower course, partly to Portugal and partly to Spain. The province of Algarve, situated at the southern extremity of the kingdom, is separated from the rest by the Serra de Monchique, and forms a strip of land between the mountains and the sea, which has a general slope to the south, and is traversed by numerous torrents running from north to south.

Climate, Products, &c.—The climate of Portugal presents considerable variations in the northern and the southern provinces. The southern provinces are very hot in summer and are subject to droughts; upon the whole however the climate may be said to be healthy, with the exception of a few spots south of the Tagus and near Setubal. The products of the country are—corn, Indian corn, rice, hemp, flax, honey, wax, plenty of fruits, especially excellent oranges and lemons, almonds, and abundance of good wine. The sea along the coasts and the rivers abound with fish, which is a great article of food with all classes. Sea-salt is collected in various places, particularly in the lagoon of Setubal. The sheep supply abundance of wool, of which some is equal to that of the Spanish merinos in fineness. Portugal has mines of copper, tin, and iron, of which only some of iron are worked. The manufactured articles are coarse woollen cloths in Alemtejo and Beira; linens in Minho, Beira, and Tras os Montes; silks at Campo Grande near Lisbon, and also at Oporto and Braganza; jewellery at Lisbon and Oporto. There are glass-works at Marinha Grande; paper manufactories at Alemquer, Lisbon, and Guimaraens; potteries at Lisbon, Oporto, Coimbra, Beja, Estremoz, and Caldas; cotton manufactories at Alcobaça and Thomar; and tanneries in various parts.

Population.—The population of Portugal was estimated at about three millions in 1827, but there has been no census in the present century.

The population of Portugal proper resembles in appearance and manners that of some of the neighbouring provinces of Spain, especially of Galicia, the dialect of the Gallegos being also akin to the Portuguese language. But the Portuguese differ considerably from their neighbours of Castile and Leon, both in their manners and character, and the difference has forcibly struck most travellers who have crossed the eastern frontier of Portugal, which in several places is not marked by any geographical boundary. On the Portuguese side of the line the villages are wretched in the extreme; the inhabitants are filthy both in their houses and persons, and the peasants seem dejected, indolent, and spiritless. The Spanish villages on the other side are comparatively clean, and the Spanish peasants look manly, robust, and active. People have endeavoured to find a reason for this difference in the municipal or rather communal institutions of Spain, which even under the absolute monarchy retained their original freedom. [AYUNTAMIENTO.] In some provinces of Portugal however, especially in the mountainous districts, such as Tras os Montes, the peasantry are superior in activity and spirit to the rest, and it was mostly from those districts that the fine regiments of light infantry called Caçadores were raised, which behaved so remarkably well throughout the Peninsular war.

With regard to the educated classes, those of Portugal are generally polished in their manners, courteous to strangers, insinuating, fond of conversation, and perhaps more pleasing in their outward address than the generality of the corresponding classes in Spain. The 'fidalgos,' or provincial nobility, are very numerous, though mostly poor.

Education.—Education in Portugal is lower than in Spain. The capital of the kingdom however is not wanting in those literary and scientific institutions which, in any well regulated country, are calculated to encourage and advance science. Besides an observatory, an establishment which has in some degree contributed to the advancement of astronomy, there are at Lisbon a royal naval school, an academy of civil and naval architecture, fortification and artillery, and drawing, painting, and sculpture; a college of surgeons, a commercial school, a royal military college, and another where the modern and antient languages, together with geometry, physics, and philosophy, are taught. The Royal Academy of Sciences, which holds the first rank among the scientific institutions of the kingdom, likewise holds its sittings at Lisbon. A society for the encouragement of national industry was established in Lisbon during Dom Pedro's regency. There are also in the capital extensive public libraries, a botanical garden, a museum of natural history, and various other scientific collections; a musical seminary, and a college for Irish missionaries. Yet with all these advantages science and literature are now in Portugal at the lowest ebb. According to Balbi, there were only sixteen printing-offices in all Portugal in 1827; one in Coimbra, three in Oporto, and twelve in Lisbon, which three places were the only towns that contained libraries or establishments for the sale of books.

Revenue, Trade, &c.—The public revenue in 1837 was reckoned at a little more than two millions sterling, and the expenditure exceeded it by nearly half a million. The public debt was above sixteen millions sterling. The present revenue of Portugal arises chiefly from the customs. The foreign trade is principally in the hands of English merchants. Most of the Portuguese wines and other produce are consumed in England. The direct trade between the ports of Great Britain and those of Portugal was formerly carried on chiefly in English bottoms; but more recently nearly one-third of the ships engaged in this trade are Portuguese, and the trade with Ireland is almost wholly carried on in Portuguese vessels. Internal commerce suffers from the want of good roads. There are no canals, and the few rivers which are navigable are not so at all seasons. Of late years the useful arts have made some progress; but few if any of the products of Portuguese industry can enter into competition with the corresponding articles of foreign manufacture.

Navy and Army.—The navy of Portugal now consists of two ships of the line, four frigates, and some smaller vessels. During the fifteenth and sixteenth centuries it was the largest in the world. The Portuguese navy was almost entirely destroyed by the Dutch and the English in their wars with that country when it formed part of the Spanish dominions; and although it revived under the first sovereigns of the house of Braganza, it again declined, and is now reduced to its present low condition. The best sailors are from the Algarve and the Azores. There is no other naval station in the kingdom besides Lisbon, where there are an arsenal, dock, marine school, and other naval establishments. The land forces of Portugal have lately varied between 25,000 and 30,000 men, according as the rebels, who still hold out in the fastnesses of the Algarve, have risen to importance. The uniforms and accoutrements of the men resemble those of the British troops.

Religion.—The whole Portuguese nation professes the Roman Catholic religion. At the head of the clergy is the patriarch of Lisbon, who has five suffragan bishops, besides four foreign bishops, and the archbishops of Braga in the north and Evora in the south, who have each four suffragan bishops. The monastic clergy previous to the late revolutions do not appear to have been so numerous as was generally supposed by foreigners. It is stated in a work published towards the end of the last century, to have consisted of about eight thousand monks. Among the Portuguese convents, four were rich, namely, those of Alcobaça, Thomar, Mafra, and Santa Cruz of Coimbra. One half of the remainder were of the mendicant orders, and the rest had a limited income just sufficient for the subsistence of their inmates. Such is the statement of the work above mentioned, which gives the monastic statistics of Portugal as they were at the end of the last century. (*Os Frades Julgados no Tribunal da Razão; Obra Posthuma da F. Doutor Conimbricense.*) 'The very hospitality,' observes the author, 'for which monasteries have long been famed, has given occasion to slander against them. Foreign travellers of distinction, who had no local knowledge of persons and things, being occasionally received in monastic houses and treated according to their rank, have assumed that the inmates lived generally in the same style as they treat their distinguished guests. Had they shared the common fare of the refectory, they would have formed a different judgment. The convents of men were suppressed in May, 1834, by Dom Pedro, the father of the present queen of Portugal, and their property has been annexed to the domain of the state. The monks are allowed a small pittance from the treasury.

Though catholicism is the religion of the state in Portugal, and the new constitution contains no article allowing any other worship, other creeds are tolerated, and the English merchants who reside at Lisbon, Oporto, and other commercial towns are nowise molested.

Political Divisions.—Portugal and the Algarve were divided for administrative purposes into six provinces, namely, ENTRE DOURO E MINHO, TRAS OS MONTES, BEIRA, ESTREMADURA, ALENTEJO, ALGARVE. Each province was divided into comarcas, and each comarca into parishes. A description of each province is given under its proper head. The Cortes have lately made a new territorial division of the kingdom into twelve provinces, which are subdivided into twenty-six comarcas, which are again further divided into julgados.

Government and Constitution.—During the middle ages feudalism was as prevalent in Portugal as in Spain, but the king was less restrained than in any other kingdom in the Peninsula; for though Portugal had very early popular representation, the deputies of the towns were fewer, not so well organised as a political body, and consequently much less influential than in Castile or Aragon. The first instance of popular representation in Portugal occurred in 1143, when the three estates met at Lamego, to confirm Alfonso I. in the title of king, which he had received from the soldiers after the battle of Ourique. Again, in 1181, and in the lifetime of Alfonso, the Cortes met, and gave the nation the celebrated code and constitution known as the 'Laws of Lamego.' By this constitution the crown was made hereditary in the royal family, but could pass to the collateral lines only with the consent of the estates. If the king left no male issue, the succession devolved on the eldest daughter, provided she married a native prince or a noble; but if she gave her hand to a foreigner, she was *ipso facto* excluded from the throne. Hence Beatrix, daughter of Ferdinand, was deprived of the succession for having married Juan I. of Castile. But the Cortes of Portugal, like those of other states in the Peninsula, fell by the repeated attacks and encroachments of the crown and the inability or unwillingness of the people to defend their rights. The kings of the house of Braganza ruled as despotically as their predecessors, and the constitutional liberties of Portugal were forgotten. At last, in 1820, after a momentary adoption of the Spanish constitution, a new one was framed, the principal features of which were a conditional veto in the king, only one chamber, and the election of the deputies to be made by electors chosen by the people from among all landholders paying a direct tax of about ten shillings. This constitution was abolished in 1823. In June, 1824, John VI. issued a decree reviving the old constitution, and summoning the Cortes of Lamego; but the Spanish government, fearing that the example of Portugal might awaken a similar feeling among their subjects, opposed the measure, and it was never carried into effect. In April, 1826, Dom Pedro granted his subjects a constitution, which established two chambers (the members of the higher being hereditary), and in other respects resembled the French charter. Though more monarchical in its tendency than that of 1820, the *carta* of Dom Pedro satisfied the enlightened part of the nation; but it was strongly opposed by the *Septembristas*, or partisans of the old one, who more than once succeeded in overturning it and re-establishing the old form of government. At last, in 1836, another constitution, neither so free as the former nor so monarchical as the latter, was sanctioned by the Cortes. This constitution establishes two chambers, both elective, and determines that no citizen can be an elector unless he possesses an income of 80,000 reis (20*l.*) arising from landed property.

By the separation of Brazil, the Portuguese monarchy has been shorn of the brightest jewel of its crown. The remaining dependencies of Portugal are—1, the Azores; 2, Madeira and Porto Santo; 3, the islands of Cape Verd [Verde]; 4, the islands of San Thome and Do Principe; 5, the captaincy or government of Congo or Angola; 6, the government of Mozambique on the eastern coast of Africa; 7, the government of Goa in the East Indies; 8, that of Macao on the coast of China; 9, some small settlements at Timor and other neighbouring islands: all these are described under the above heads. Most of these Portuguese settlements, especially those on the coast of Africa, are in a state of decay. The wretched state, both physical and moral, of those on the Mozambique coast, is well depicted in Captain Owen's 'Narrative of Voyages to explore the coasts of Africa, Arabia, and Madagascar.' It is impossible to ascertain the population of all these dependencies, some of which, such as Congo and Mozambique, include large inland tracts of country, which are only nominally subject to the Portuguese.

(Miñano, *Diccionario Geografico de España y Portugal*; Balbi, *Statistique du Portugal*; Kinsey, *Portugal illustrated.*)

History.—The early history of Portugal cannot conveniently be separated from that of the other kingdoms in the Peninsula. The Iberians and the Celts were the oldest inhabitants of the country; and it is to be inferred that the Phœnicians, who settled among the Turdetani, likewise visited its shores. When the Carthaginians invaded the Peninsula, their general Hamilcar overran and subdued its western provinces. The Romans, who succeeded the Carthaginians as masters of the Peninsula, governed by their prætors the province of Lusitania, the antient limits of which have been variously defined by different authors. Strabo (iii., p. 152) intimates that it extended from the Tagus to the Ocean on the north and on the west, and was bounded on the east by the Carpetani, Vettones, Vacæi, and Callaici. But when Augustus had divided the Peninsula into three provinces, Bætica, Tarraconensis, and Lusitania, the last only comprised the country between the Douro (Durius) and the Guadiana (Anas), extending on the eastern side as far as Libora (now Talavera) and Augustobriga (now Puente del Arzobispo) on the Tagus, or the frontiers of the Vettones and Carpetani. It thus comprised the greater part of the modern kingdom of Portugal, besides a considerable portion of Leon and Estremadura. This region was inhabited by various nations, of whom the principal were the Lusitani, Artabri, Celtici, Turduli, &c. [Spain], all of whom were rude but warlike people, who made several attempts to shake off the yoke of the republic. Viriatus, who contended so long and successfully with the best Roman legions, was a Lusitanian shepherd. When Spain was inundated by the Germanic tribes, Portugal shared in the general devastation; and when, at the beginning of the eighth century, the torrent of Arabian conquest spread over the Peninsula, the territories and towns of Portugal were as easily subdued as the remainder of Spain. [Moors; Musa.]

During the first century after the Saracen invasion, Portugal in the hands of the unbelievers shared the fate of the rest of Spain. In the ninth century however the greater part of northern Portugal was wrested from the Mohammedans, and became subject to local governors dependent on the counts of Galicia. The south still remained in the hands of the Mohammedans until towards the close of the twelfth century, when Santarem, Lisbon, and Cintra were reduced by Alfonso VI., the conqueror of Toledo. As these conquests however were continually exposed to the irruptions of the Almoravides, that monarch, in 1095, conferred upon his son-in-law Henry of Besançon, who was descended in a direct line from Hugues Capet, the government of the subdued territories from the Minho to the Tagus, with the title of count. At the same time Henry, who took up his residence at Guimaraens, was permitted to hold in his own right whatever conquests he might make from the Moors beyond the Tagus. In this manner he reduced most of the Mohammedan governors of fortresses south and east of the Tagus to the condition of tributaries. On his death in 1112, his son Alfonso succeeded to the dignity of count, which the Castilian king had previously rendered hereditary in his family. The new count proved a more formidable enemy to the Mohammedans than even his father. In 1139, having resolved to reduce the Moorish fortresses west of the Guadiana, he assembled a powerful army at Coimbra, and advanced towards Badajoz, the governor of which place, having received considerable reinforcements from Africa, hastened to meet him. The Moors were however defeated with great loss at Ourique in 1139.

Portugal under the Kings of the House of Burgundy (1139-1557).—After the victory of Ourique, Alfonso, who had for some time contemplated throwing off his allegiance to his lawful sovereign, caused himself to be proclaimed king by the soldiers. The cortes of Lamego confirmed his title, and gave to the new kingdom, which was acknowledged by the pope Alexander III., a code of laws and a constitution. In 1146 Alfonso retook Santarem from the Moors, and, soon after (1147), Lisbon with the assistance of a fleet of crusaders under the command of William Longsword [Lisbon.] In 1162 he founded the two military orders of Avis and San Miguel del Ala, which still exist. The remainder of his reign was spent either in war with the Moors, or in defending his dominions against the kings of Leon and Castile, who disputed his claim to the royal dignity. This king, whose memory is held in the greatest veneration by the Portuguese, died at the close of the year 1185. He was succeeded by Sancho I., his eldest surviving son, whose reign was by no means so glorious. Though with the aid of some crusaders, whom a tempest forced to take refuge in the port of Lisbon, he took the town of Silves in Algarve: and though he afterwards defended his conquest with success against the Almohades in 1190, he nevertheless lost Palmella, Alcaçar do Sal, Coimbra, and other important fortresses; some of which he did not recover for a long time. Sancho died in 1211. His successor, Alfonso II., had at first to sustain a war against the king of Leon, who penetrated into his dominions; but a peace being concluded, he gave all his attention to the prosecution of the war against the Mohammedans. Though he was not present at the battle of Tolosa (1212), he nevertheless sent to Alfonso III. of Castile his contingent of troops. In 1217 the arrival of another fleet of crusaders in his port led him to undertake, with their aid, the siege of Alcaçar do Sal, and after a blockade of several months, and a battle fought under its walls, that important fortress was again recovered. This conquest was followed by that of Moura and other towns in Alentejo. His son Sancho II., who succeeded him in 1223, was animated by the same military ardour. Soon after his accession he recovered Elvas, Jarumeñha, and Serpa. He then carried the war into Algarve, and was victorious in several partial engagements. He also made successful incursions into Alentejo, which he appears to have completely delivered from the infidels. At the same time the knights of Santiago, to whom he had entrusted the defence of the frontier fortresses, reduced Tavira, Faro, Loule, and other towns in Algarve. The populous city of Silves, which had been regained by the Mohammedans, was likewise recovered by the knights of that Order. In 1245 Sancho, having become highly unpopular with the clergy, whose privileges he attacked, an application was made by them to Innocent IV., who was then presiding over a general council at Lyon, and who, in concert with the fathers, issued a decree, by which, though the royal title was left to Sancho, the administration of the kingdom was declared to be vested in the Infante Alfonso, brother of the king. After some unsuccessful attempts to resist the papal decree, the dethroned monarch retired to Toledo, where he ended his days early in 1248. Alfonso III. completed the conquest of Algarve, which his predecessor had begun, and was thence called the 'Restorer.' Though he owed his throne to a decision of the holy see, he showed as little disposition as his brother to comply with its demands. The whole of his reign was passed in disputes, either with his prelates, whose religious privileges he sought to curtail, or with the military orders, whose possessions had from conquest become too large. In both instances however he was forced to yield. Alfonso died in 1279, and was succeeded by his son Dinis, who, like his father and most of his predecessors, was long at war with the church. Having at last convoked a meeting of his prelates, he effected a reconciliation with the church by yielding in most points, though he was completely successful in the main one, namely, that no order of ecclesiastics should be allowed to hold land in his kingdom. The reign of Dinis was not signalised by foreign conquest; the Mohammedans being then reduced, through the activity of Ferdinand III., to the limits of the kingdom of Granada. He had however to contend with his rebellious son Alfonso, who, aided by a turbulent and discontented nobility, more than once took the field against him. The name of Dinis has passed to posterity coupled with the glorious epithets of 'the just,' 'the husbandman,' and 'the father of his country.' He was the first who turned to account the favourable position of the country for commerce, and who, by awaking the enterprise of his subjects, laid the foundation of the greatness of Portugal in the succeeding century. Himself a scholar and a poet, he was a generous patron of science, which he fostered in his states. In 1284 he laid the foundation of a university in Lisbon, which he afterwards (1308) transferred to Coimbra. With the confiscated possessions of the Templars, he founded and endowed the new military order of Christ.

Dinis was succeeded, in 1325, by his son Alfonso IV., surnamed the Brave, whose reign was almost entirely spent in war with his namesake of Castile. Peace being at last concluded between them by the interference of the pope, he joined his arms to those of his rival, and assisted him in humbling the power of the Mohammedans, who, reinforced by their African neighbours, threatened once more to accomplish the entire subjugation of the Peninsula. His son Pedro I., who succeeded him in 1357, is chiefly known by his secret marriage with the celebrated Inés de Castro, and the tissue of crimes caused by that union. He was succeeded in 1367 by his son Fernando I., who, on the death of Pedro the Cruel of Castile without male heirs, assumed the regal title and arms of that kingdom, as the grandson of the Princess Beatrix, daughter of Sancho the Brave of Castile. His entire reign was spent in war with the bastard Enrique, who had usurped the throne of Castile; but though he wasted his resources, he gained no advantages. With the death of this monarch, in 1383, the male line of the Burgundian princes became extinct in Portugal. His daughter Beatrix, who had married Juan I. of Castile, was the true heir to the throne, but the Portuguese were so averse to a connection with Castile, that, on the marriage of the princess with the Castilian king, it had been expressly stipulated that in case of Fernando's death the government should be vested in a regency until Beatrix had a son capable of assuming the sovereignty. Accordingly Dom Joam, grand-master of the order of Avis, an illegitimate son of king Pedro I., was appointed regent, and two years afterwards was proclaimed king by the states assembled at Coimbra in 1385, to the prejudice of Enrique, son of Beatrix, the lawful heir to the Portuguese throne. Joam I. maintained the possession of his usurped throne with great ability and courage. After several successful encounters with the troops of the Castilian king, he defeated them with great loss at Aljubarrota, a village in Portuguese Estremadura (August 14, 1385). With this king begins the native line of Portuguese kings, as well as the foreign conquests and voyages of discovery which established the greatness of Portugal. The important fortress of Ceuta was wrested from the Moors in 1415. Henry, surnamed the Navigator, one of the king's sons, who had made the mathematical sciences and navigation almost his sole study, first set on foot those enterprises of discovery and commerce which raised Portugal so much above contemporary states. He made a first voyage of discovery in 1419, which proved unsuccessful. In the following year, with three vessels, he reached the Madeiras, which had been previously discovered by Machin, an Englishman. A subsequent expedition penetrated as far south as Sierra Leona, within three degrees of the line. The reign of Joam I. is justly considered one of the most glorious which Portugal ever had. He improved the administration of the kingdom, and introduced many salutary reforms into the courts of justice. He transferred the royal residence from Coimbra to Lisbon. At his death in 1433, Joam I. was succeeded by Duarte, under whose reign happened the disastrous expedition against Tangiers, in which the Portuguese lost an army, besides one of their leaders, the Infante Dom Fernando, who remained a prisoner in the hands of the Moors (1437).

Duarte, who died of the plague at Tomar, was succeeded by his eldest son Alfonso V.; but as he was only six years of age on his father's death, the regency devolved, according to his will, upon the queen-mother, a very able princess. Under the reign of this king the career of African conquest was ardently prosecuted. The port of Alcaçar Saguer, on the African coast, was invested and taken in 1457. Arsilla, a port on the Atlantic, was next stormed, and the inhabitants were put to the sword (1471). The populous city of Tangiers, which had hitherto defied all the power of Portugal, was next reduced, chiefly through the instrumentality of his eldest son Joam, who for his gallant behaviour on this occasion received the honour of knighthood. Towards the close of his reign Alfonso was induced to favour the pretensions of La Beltraneja to the throne of Castile, and to make war upon Ferdinand and Isabella, whom he considered as usurpers. But his troops having been completely routed at Toro, in 1476, he was obliged to accept peace on very humiliating conditions (1479). Alfonso died of the plague in 1481. He founded the order of the Tower and Sword. He was a great patron of literature, and the first Portuguese king who collected a library, and ordered the national history to be treated by competent writers. His reign was likewise signalised by the progress of maritime discovery, and the Azores, with the Madeiras, the Canaries, Cape Verd, and other islands west of the African continent, were either discovered or colonised through the persevering efforts of the Infante Dom Enrique. Joam II., who succeeded Alfonso II., was justly considered one of the ablest monarchs that ever sat on the throne of Portugal. He was the first who coped with the nobles, whose power had greatly increased under his predecessors. All grants of crown-lands made by his indulgent predecessors were revoked, and the judicial privileges of the nobility were restricted by the appointment of plebeians to all the magistracies. Some attempts having been made by the nobles to resist the king's orders, the duke of Braganza, who was their representative, was beheaded in 1463, and the duke of Viseo was put to death by the king's own hand in 1483. In this reign the Portuguese spirit of maritime discovery was carried to the highest pitch. A fort was built on the coast of Guinea, which had been discovered under the reign of his predecessor, for the purpose of maintaining a permanent commercial intercourse with the natives, and from this moment Portugal derived from that coast a considerable profit in ivory and gold, which supplied ample resources for new enterprises. This active spirit received fresh impulse from the capital and industry of the Spanish Jews, 83,000 in number, whom the intolerant rigour of Ferdinand and Isabella had driven from their dominions, and who were admitted in Portugal on the payment of a capitation tax.

In 1481, Joam, having conceived that by coasting along the African continent a passage to the East Indies might be discovered, dispatched two of his subjects, Pedro da Covilhan and Alfonso da Payva, into India and Abyssinia, to discover the route to and between these vast regions, and learn what advantages Portuguese commerce might derive from the knowledge thus acquired. After reaching Alexandria, the two travellers separated, Covilhan for India, Da Payva for Abyssinia, agreeing to rejoin each other in a given period at Cairo. Covilhan embarked on the Red Sea, and visited the most famous cities of India as far as the Ganges. On his return he sailed along the shores of Persia, Arabia, and Africa, as far as Mozambique, where he learned that the continent terminated in a great cape. Having heard at Cairo of his companion's death, he settled in Abyssinia, whence he wrote to the king, and sent him a chart of the maritime places that he had visited. These discoveries encouraged Joam to attempt a passage to India. The kingdoms of Benin and Congo were first discovered, the former by Joam Alfonso de Aveiro, the latter by Jayme Cam. [BENIN; CONGO.] The Portuguese next formed a settlement on the coast of Senegal, the king of which country had previously visited Lisbon. At last, in 1487, an enterprising officer named Bartholomeo Diaz discovered and doubled the southern cape of Africa, which, from the good expectations which it encouraged, was called O Cabo de Boa Esperanza. [CAPE OF GOOD HOPE; AFRICA.] The success of these expeditions, and the wealth which the commerce of the newly discovered countries poured into Portugal, may perhaps be some excuse for the neglect with which the proposals of Columbus to seek new lands in the west were received at the Portuguese court. However, no sooner was the happy issue of the Genoese pilot's discovery made known in Portugal, than Joam fitted out a fleet for the West. This led to a dispute between Portugal and Castile, which Pope Alexander VI. finally settled by a line of demarcation drawn one hundred leagues west of the Azores and Cape Verd Islands, thus separating the future conquests of the two nations. [COLUMBUS; AMERICA.] Joam II. died universally regretted, in 1495. He was succeeded by his cousin Manoel, who steadily pursued the career of maritime discovery.

About the close of 1497 the passage to India by sea was effected by a squadron of five vessels, under the orders of Vasco de Gama, who returned to Lisbon, in September, 1499, after an absence of little more than two years. A fleet of thirteen vessels was next fitted out and sent in the same route, under the direction of Pedro Alvares Cabral, who discovered Brazil, and touched afterwards at Quiloa, Calicut, Cochin, and Cananor, with which countries he opened an intercourse. In 1502, Vasco de Gama, being sent to India a second time, with ten sail, permanently established the Portuguese authority in India. [GAMA, VASCO DE.] The next considerable armament which the Portuguese king fitted out for India consisted of thirteen vessels and 1200 men, which were put under the orders of Lope Suares. Soon after Francisco da Almeida was sent to administer the Portuguese conquests in India. His son Lourenzo took possession of the Maldive Islands, and established factories in Ceylon, while other expeditions, sent in various directions, formed commercial establishments on the island of Sumatra, as well as at Malacca. Alfonso da Albuquerque, by whom Almeida was replaced, was one of the ablest captains of his age, and the Portuguese flag waved triumphantly along the vast African continent from the Straits of Gibraltar to Abyssinia, and along the Asiatic from Ormuz to Siam. [ALBUQUERQUE.] On this distant stage were performed many acts of heroism, which gave a tone to the national character. The conquests in Northern Africa, though unprofitable, contributed to keep up the martial spirit of the Portuguese. Lisbon became the most important commercial city of Europe; and Portugal, the most insignificant of the European states in extent of territory and population, grew a powerful monarchy.

In the reign of Joam III., who succeeded his father Manoel in 1521, Indian discoveries and commerce were still further extended. But the rapid accumulation of the precious metals at home without a corresponding increase of domestic industry, and the loss of so many of her most vigorous youth, who were sent to extend or defend her conquests, began to be as sensibly felt in Portugal as they afterwards were in Spain. The introduction of the Inquisition, in 1536, which, as in Spain, was at first intended only against the Jews, greatly contributed to increase the misery caused by bad administration and the vicious course of policy pursued with regard to the colonies. The enlightened Joam II. had allowed the Jews to settle in his dominions, but he had subsequently been persuaded by his wife, a daughter of Isabella, to revoke his permission, and to issue an order that all the Jews living in Portugal should embrace Christianity in the course of twenty years, under the penalty of being deprived of their children and made slaves. Many thousands having been induced by this measure to conform publicly at least to the Christian usages, while they secretly adhered to their faith, the Inquisition began to search out the delinquents, against whom, when discovered, the most revolting cruelties were practised. The Jews were exterminated, or fled from Portugal: but although the object for which that tribunal was instituted no longer existed, it still continued a powerful political weapon in the hands of the absolute kings of Portugal. [OFFICE, HOLY.] As injurious in its consequences as the Inquisition was the admission of the Jesuits into Portugal, under Joam, the first European monarch who permitted them to enter his dominions. [JESUITS; LOYOLA.] The education of his grandson Sebastian, the heir-apparent to the throne, was likewise entrusted to the Jesuits, who inspired the young prince with that spirit of bigotry and that fanatical ambition which led to his death. In 1557, on the death of his grandfather, Sebastian being only three years old, the regency was vested in the widowed queen Catherine of Austria. Scarcely however had the young prince reached his fourteenth year—the period of his majority—when he began to turn all his thoughts towards the prosecution of the African war; and he sailed in 1574, in opposition to the remonstrances of his wiser counsellors. Four years afterwards, in August, 1578, the memorable battle was fought by which Portugal lost her king, and began rapidly to sink from her former prosperous condition.

Portugal subject to Spain (1580-1641).—After the short reign of Cardinal Enrique, Sebastian's uncle, who was proclaimed in 1578 and died in 1580, Philip II. of Spain, the most powerful candidate for the throne, obtained possession of it, not without considerable opposition on the part of the Portuguese, who, rather than submit to the Spanish yoke, elected Dom Antono, prior of Crato, a bastard of Dom Luis, brother of Joam III. Portugal thus became annexed to a kingdom which from this time was hastening to its own decline by a series of unsuccessful wars and by its unwise administration. England and Holland, the powerful enemies of Spain, now attacked Portugal, the wealth of which promised them a rich booty, and whose defenceless maritime possessions were gradually torn away. The Dutch took the Moluccas and a great portion of Brazil in 1624. They likewise took possession of the Portuguese settlements on the coast of Guinea (1637), and forced their way into the rich markets of the East Indies. Spain, then at war with the European states, could not attend to the defence of those distant possessions, and the colonies of Portugal were one by one wrested from her by her active enemies the English and the Dutch. The internal administration of that kingdom was in the hands of Spanish governors, who made themselves obnoxious by their rapacity and injustice. At last the Portuguese nobility, exasperated by this oppression and the contemptuous conduct of Olivarez, the minister of Philip IV., entered into a conspiracy, and on the 1st of December, 1640, Joam de Braganza, a descendant of the old royal family, was placed on the throne. In justification of this revolution, which restored the independence of Portugal, the Cortes of 1641 issued a manifesto addressed to the powers of Europe. The war with Spain, which was the result of this measure, and lasted during the reign of Joam, as well as that of his son Alfonso VI., was terminated in 1668, by a treaty of peace, and a cession on the part of Spain of all her claims on Portugal.

Portugal under the Monarchs of the House of Braganza (1641-1840).—Joam IV., the first Portuguese king of the house of Braganza, died in 1656. He was succeeded by his son Alfonso VI., who completed the work begun by his father and firmly established Portuguese independence. A treaty of peace was also concluded with Holland by English mediation, by which Brazil was restored to Portugal; but its former greatness could not have been restored, even had the princes of the line of Braganza displayed more wisdom and vigour than they actually did. Pedro II., who succeeded his brother Alfonso IV. in 1683, took part with the allies against Philip V. of Spain. From this time date the relations and alliance of England with Portugal. A commercial treaty with that kingdom had already been made, under the first sovereign of the house of Braganza. A new one was concluded in 1703 by the English ambassador Mr. Methuen, which secured to England the advantages of the newly discovered mines in Brazil. During the long reign of Joam V., which lasted from 1707 to 1750, some vigour was displayed in regard to the foreign relations, and several attempts were made for the promotion of the national welfare at home, such as the restriction of the powers of the inquisition, and the increase of the revenue by encouragement of trade and manufactures. But that institution was too formidable an adversary to allow the object to be accomplished; and although the resources of the country were really increased, immense sums were thrown away on the sumptuous monastery at Mafra and the dear-bought permission from the pope to institute a patriarch of Lisbon. Under his son and successor Jossé I., who ascended the throne of Portugal in 1750, the spirit of reform and improvement, which had sprung up in Spain, became also visible in Portugal. His minister, the marquis of Pombal, a vigorous reformer, followed the steps of Aranda and Floridablanca, who, with equal success, were healing the wounds which bad administration had inflicted upon their own country. The Jesuits and the nobility, who under the preceding reign had exercised a secret and dangerous influence, were vigorously attacked. The exposure of the power which the former had usurped in Paraguay—their conduct at the time of the earthquake, which in November, 1755, laid so great a portion of the capital in ruins—the conspiracy against the life of the king (a charge however which appears destitute of all foundation) in 1759—led at last to the suppression of the Order. In 1757 they had been deprived of the post of confessors to the royal family and forbidden the court; two years after, they were banished from the kingdom and their estates confiscated, a measure which was readily imitated a few years afterwards (1766) by their neighbours of the Peninsula. [Jesuits.]

On the accession of Maria Francisca Isabel, eldest daughter of Jossé, in 1777, the marquis of Pombal lost the influence that he had possessed. To him Portugal owed her revival from a state of lethargy, and although most of the useful regulations which he introduced did not survive his fall, yet the enlightened views which he disseminated, and the national feeling which he awakened, were not without permanent effects. During the reign of Maria, the power remained almost entirely in the hands of an ignorant nobility and of a still more ignorant and ambitious clergy. In 1789, on account of a serious indisposition of the queen, her eldest son, Joam Maria Jossé, prince of Brazil (the title of the prince royal until 1816), was declared regent, and soon after, her malady having terminated in mental alienation, the prince was declared regent with full regal powers. The connection of Portugal with England involved Joam VI. in the wars against France; but in 1797, the commercial distress, the accumulating debt, and the threatening language of Spain, now in the interests of France, led to a peace with that power. The disasters of the French arms in 1799 encouraged the regent to renew hostilities, in alliance with England and Russia; but French politics again preponderating in Madrid, the Prince de la Paix (Godoy), then prime minister, was persuaded to declare war against Portugal, which kingdom he invaded in 1801. Hostilities however terminated the same year, by the treaty of Badajos, by which Portugal was obliged to cede to Spain the important fortress of Olivenza, besides paying a large sum of money as indemnity for the expenses of the war. Portugal, in the meantime, preserved a mere shadow of independence by the greatest sacrifices, until at last General Junot entered that country, and the house of Braganza was declared by Napoleon to have forfeited the throne, owing to the refusal of Joam VI. to seize the British merchandise in his dominions. The regent now put himself entirely under the protection of the English, and in November, 1807, embarked for Brazil. Junot entered the capital on the next day, and Portugal was in every respect treated as a conquered country. In order to oppose the French, a British force was landed, and numerous bodies of native troops in the northern provinces, having taken up arms, prepared to maintain their independence. A junta was in the meanwhile established at Oporto to conduct the government. After some partial engagements, the decisive battle of Vimeira was fought, 21st of August, 1808, in which the British troops, under Sir Arthur Wellesley (now duke of Wellington), defeated the French under Junot. This signal victory was followed by the celebrated convention of Cintra, and the evacuation of the country by the French forces.

The Portuguese now took an active part in the Peninsular war. On the death of Maria Isabella (1810), John VI. was called to the throne of Portugal, which he occupied conjointly with that of Brazil, where he continued to reside. This removal of the court to an American colony was not without consequences. Brazil attempted to withdraw itself from dependence on Great Britain, and became in the sequel a separate state. In Portugal, on the contrary, the influence of England continued, and the condition of the kingdom was not essentially changed. The peace of Paris, in 1814, by no means answered the expectations of the nation, though it had exerted itself vigorously in the common cause. Spain succeeded in evading the restitution of Olivenza, which had been provided for by the Congress of Vienna, whilst Portugal was obliged to restore some part of French Guiana, which had been taken from the French. The court of Rio Janeiro therefore occupied the Banda Oriental [Brazil], and Portugal was involved in new difficulties with Spain. In 1815 the Inquisition was for ever abolished in the Portuguese dominions, and the Jesuits were refused admission into them, while the Jews were, at the request of the pope, in 1817, allowed the same privileges which they enjoyed in the Roman states.

On the 24th of August, 1820, the cry for liberty which was raised in Spain, was responded to in Portugal, and a Revolution commenced, in which the army and the citizens acted in concert. The soldiers were induced by their officers to swear obedience to the king, the Cortes, and the constitution which should be adopted. The magistrates and citizens declared also in favour of that measure, and a junta was established, which addressed a manifesto to the nation, stating that the convocation of a popular assembly and the adoption of a free form of government were the only means of saving the state. All the garrisons, from the Minho to Leiria, joined in the movement, which was not opposed by the troops of the regency established at Lisbon. At last, on the 15th of September, 1820, all the troops and the citizens of Lisbon unanimously proclaimed the constitution, and the cessation of the absolute government which had hitherto prevailed in Portugal. A provisional government was immediately established, which acted in union with the junta at Oporto. In the meantime Count Palmella, the head of the regency, was dispatched to Rio Janeiro with an account of what had passed, and a petition that the king Joam VI. or the prince royal Dom Pedro would return to Lisbon. The Revolution was unattended either by violence or bloodshed; but the liberal party, being desirous of adopting the Spanish constitution, obliged the supreme junta to administer to the civil authorities and to the army the oath of obedience to it. This measure however being disapproved by a considerable party of the people, four members of the junta and 150 officers resigned; upon which it was agreed that no part of the Spanish constitution should be enforced until it was acted upon by the Cortes, with the single exception of the law of elections, which was definitively adopted for the election of the first Cortes. The Cortes having assembled in 1821, under the presidency of the archbishop of Braga, various laws were passed, among which freedom of person and property, the liberty of the press, legal equality and the abolition of privileges, the admission of citizens to all offices, and the sovereignty of the people, were passed almost unanimously. With respect to the organization of the chambers and the royal veto, various opinions prevailed, but at last a large majority decided in favour of one house and a conditional veto.

After some disturbances in Brazil, Joam VI. sailed for Portugal, where he was not allowed to land until he had given his consent to several acts of the Cortes, which imposed restrictions on his power, and had sworn to observe the new constitution. The ambassadors of Russia and

Austria left the court; Brazil separated itself from Portugal; and the country was disturbed by various attempts in favour of the old system of government. In the meanwhile the constitution was completed by the legislative assembly, and publicly sworn to by the king on the 1st of October, 1822, but the Infante Dom Miguel, assisted by the Count of Amarante and other noblemen, resolved to overthrow it. The royalist forces under Amarante having been defeated, the insurgents took refuge in Spain, and in May, 1823, established at Valladolid a Portuguese regency, under the presidency of the patriarch of Lisbon, who had been banished from the kingdom. Dom Miguel, after insidiously assuring his father of his determination to uphold the constitution, repaired to Villafranca, where, being joined by some troops, he openly declared against the Cortes. The garrisons of some provincial towns having embraced his cause, John VI. was obliged to yield, and having appointed a new ministry, declared the constitution of 1822 null; the national guards were disarmed, the church property restored, the patriarch of Lisbon recalled, Count Amarante reinstated in his rank and rights, several members of the Cortes imprisoned or exiled, and the liberty of the press abolished. But Joam VI., who under any other circumstances would have been an excellent king, was unwilling altogether to deprive the Portuguese of a liberal government, and a commission was appointed, at the head of which was Palmella, to draw up a constitution adapted to a representative kingdom. This again failed through the intrigues of the apostolical party, supported by France and Spain; the queen returned to Lisbon, and Amarante made his entry into the capital, and was soon after created marquis of Chaves, the name of the town where he had organised his insurrection against the Cortes. Dom Miguel, who had been appointed commander-in-chief of the army, and invested with supreme power, filled the offices with men devoted to the cause of absolutism. He also meditated an expedition to Brazil, but an exhausted treasury prevented him from carrying his plan into execution. At last the absolutist party determined to annihilate the hopes of the constitutionalists, and to put an end to the system of moderation to which the king still adhered. On the 30th of April, 1824, Dom Miguel called the troops to arms, and issued a proclamation, in which he declared that it was his intention to deliver the king his father from the tyranny of the revolutionists who surrounded his person. By his orders the ministers and several public officers, to the number of about one hundred, were arrested on the charge of having engaged in a conspiracy against the life of the king. In the meantime the ambassadors of the foreign powers were not allowed to enter the presence of the king, who was closely watched; but having subsequently protested against this violence, Joam succeeded in escaping on board an English man-of-war at anchor in the Tagus, where, having sent for the diplomatic body, he deprived his son of command, and summoned him to his presence. Dom Miguel obeyed, confessed that he had been deceived and misguided, and received the royal pardon, with permission to travel. On the 14th of May the king returned ashore, and early in June proclaimed a sort of amnesty for the adherents of the Cortes of 1820. On the same day appeared a decree reviving the antient constitution of the state, and summoning the old Cortes of Lamego, which had not met since 1697, a measure which, being stoutly opposed by Spain, was not carried into execution. In 1825, after many difficulties and protracted negotiations, the independence of Brazil was finally acknowledged by Joam VI., who merely retained the imperial title.

Early in March, 1826, Joam VI. died, after having named the Infanta Isabel regent. She administered the kingdom in the name of Dom Pedro, the emperor of Brazil, as king of Portugal. On the 23rd of April, Pedro IV. granted the latter kingdom a constitution, which established two chambers, and in other respects resembled the French charter. On the 2nd of May however he abdicated the Portuguese throne in favour of Doña Maria da Gloria (he remaining king during her minority) on condition of her marrying her uncle Dom Miguel. But a party secretly favoured by Spain aimed at the overthrow of the constitution granted by Pedro, which had been sworn to by the queen, by the two chambers, by all the magistrates, and by Dom Miguel himself at Vienna in 1826. The marquis of Chaves and the marquis of Abrantes appeared at the head of an army of insurgents, and Spain assembled considerable forces on the Portuguese frontiers; but Portugal having appealed to England for assistance, 15,000 British troops were landed in Lisbon, and the insurrection was completely put down. In July, 1827, Pedro appointed his brother Miguel lieutenant and regent of the kingdom. The prince accordingly left Vienna, and passing through Paris and London, arrived at Lisbon in February, 1828, soon after which, in the presence of the two chambers, he took the oath to observe the charter. But the apostolical party, to whom the disposition and temper of the regent were well known, began openly to speak of Miguel's right to the throne, and to hail him as absolute king. It was determined that the regent should go to Villaviciosa on the Spanish frontier, where he might have the support of the troops under the marquis of Chaves, and overthrow the constitutional government. This project however was frustrated by the decision of Mr. Lamb, the British minister, who not only counteracted the order for the departure of the British troops then in Portugal, but prevented the payment of a loan made to Dom Miguel under the guarantee of the English government. At last, after dissolving the Cortes, who were opposed to his designs, and seeing the departure of the British troops, Dom Miguel issued a decree in his own name convoking the antient Cortes of Lamego. Part of the army however were not favourable to his projects, and on the 18th of May, Dom Pedro and the charter were proclaimed by the garrison of Oporto, which, being increased by other garrisons, marched against Lisbon. They were defeated towards the end of June, and the constitutionalists either forced their way to the Spanish frontier or embarked for Great Britain. Miguel now turned all his attention to the consolidation of his power. Having caused the Cortes to assemble (June, 1828), he was declared by that body lawful sovereign of Portugal and Algarve, chiefly on the grounds that Dom Pedro had forfeited all right to the crown, as well as to the appointment of a successor, by becoming a Brazilian citizen, and not residing in Portugal. On the 4th of July, 1826, Dom Miguel, in compliance with the decision of the Cortes, assumed the royal title. He immediately established a special commission to try all those who had taken any part in the Oporto insurrection; the prisons were crowded with individuals of all ranks, and foreign countries were filled with Portuguese emigrants. An expedition was likewise sent to those islands which refused to acknowledge his authority, all being reduced, with the exception of Terceira, where, in March, 1830, a regency, appointed by Dom Pedro, and consisting of Palmella, Villaflor, and Guerreiro, was installed. The other islands were soon retaken by the forces of the regency, and Dom Pedro having arrived in Europe, extensive preparations were made to dethrone the usurper. Meanwhile Portugal was a prey to violent political commotion. Insurrections broke out everywhere, trade was suspended, and the relations of Portugal with foreign powers were seriously compromised.

In consequence of some acts of violence against British subjects, and a refusal of redress on the part of the government, the English government sent out a fleet to the Tagus, but on its appearance before Lisbon, May, 1831, the concessions required by Great Britain were made. In July, in consequence of similar demands of the French government not being complied with, a French squadron forced the passage of the Tagus, and took possession of the Portuguese fleet, which was not restored until full satisfaction was given besides an indemnity for the expenses incurred by the expedition.

On the 24th of February, 1832, the naval forces of Dom Pedro arrived off Terceira, of which island they took possession in the name of Doña Maria, as lawful queen of Portugal. Three months after (June, 1832), an expedition 10,000 strong sailed from St. Michael's in the Azores, and on the 10th of July landed near Oporto, which city they took without opposition. The Miguelite forces laid siege to Oporto, but were defeated in several engagements by the troops of Dom Pedro, which were chiefly composed of Englishmen. After a siege of several months, during which the garrison was reduced to the greatest extremities, and the wealthy merchants in the city were almost ruined by the wanton devastation committed in their wine-vaults by the royalist troops, an expedition was fitted out by means of a loan raised in England, and Dom Pedro, encouraged by the recent victory won by Admiral Napier over the naval forces of Dom Miguel, sailed with part of his forces for Lisbon, of which he took possession with comparatively little trouble. He then established a permanent government, and shortly after sent to England for the young queen, who was received by the Portuguese nation with every demonstration of joy.

In the meantime the army of Dom Pedro prosecuted its success. Early in 1834 the strong town of Leiria was taken from the Miguelites by Marshal Saldanha; and in April a Spanish army, under General Rodil, entered Portugal for the purpose of seizing the person of the Infante Don Carlos, the pretender to the Spanish crown, who, with a few followers, had crossed over the frontier and taken refuge in Portugal. On the approach of the Spanish troops the important town of Almeida declared for the young queen. Shortly after a treaty was signed at Lisbon between England, France, Spain, and Portugal, which had for its object the pacification of Spain and Portugal by the expulsion of Don Carlos and Dom Miguel from the Portuguese territory. On the 26th of May, 1832, after the surrender of Santarem and other places, Dom Miguel was obliged to capitulate and sign the convention of Evora. He was however permitted to leave Portugal, and to embark at Monte for Genoa. This event ended the struggle, and the young queen was firmly seated on the throne of Portugal, the regency being conferred upon her father. One of the first acts of his administration was the suppression of the monastic establishments; another was the partial abolition of paper money, and the formation of a metallic currency. On the 15th of August Dom Pedro was confirmed in the regency by the Cortes, but in the following month the declining state of his health having induced him to resign his office, the Cortes in consequence declared the young queen of age. Having therefore taken the oath according to the charter, she assumed the full exercise of royal authority. Dom Pedro died on the 22nd of September, 1834. Soon after (January, 1835), Doña Maria married Duke Augustus of Leuchtenberg, who died shortly after (March, 1835), and in April, 1836, she married Prince Ferdinand of Saxe Coburg-Gotha, by whom she has issue Prince Pedro de Alcantara, born 16th of September, 1837, and Luis Felipe, born 31st of October, 1838.

Language.—The language of Portugal, like those of other kingdoms in the Peninsula, originated in a mixture of the Latin, Teutonic, and Arabic. Some writers have improperly called it a dialect of the Castilian; but, besides the striking difference in its structure and pronunciation, there can be no doubt that the Portuguese was formed earlier than the Castilian. It might more properly be called a dialect of the Galician, to which it had at first great affinity, and which it now resembles so much that the uneducated people of both countries perfectly understand each other. The *cantigas* of Alfonso X. were written in Galician, and long after the formation of the Castilian dialect Leonese and Castilian poets used the Galician or Portuguese dialect as more adapted to all kinds of poetical composition. The separation of Portugal from Spain, their wars, and the little commercial intercourse which existed between them during the middle ages, combined in course of time to make the Portuguese a different language. When Henry of Burgundy fixed his court at Guimaraens, the French knights who came with him introduced a considerable number of French words into the language of the country. The great efforts too of the Portuguese poets and prose writers in the fifteenth and sixteenth centuries to improve their native language by resisting the introduction of Castilian words, and anathematising all those who adopted the Spanish language in their writings, may be mentioned as one of the means which mainly contributed to render the tongues of Spain and Portugal still more dissimilar. The Spanish, like the Portuguese, has many words borrowed from the Arabic. Their wars with the Moors of Africa and the Mohammedans of India in the fifteenth century introduced into it many others from the languages spoken in those countries. Father Joao de Sousa published, in 1789, 4to., a vocabulary containing no less than 1400 words derived from the Eastern languages, chiefly from the Arabic. As a conversational language, the Portuguese is considered superior to the Spanish. It is more concise, easy, and simple, but not so rich. The pronunciation is difficult for a foreigner, more particularly the nasal sounds, in which it abounds. The gutturals however are neither so strong nor so common as in the Spanish; but it must be admitted that the clipping pronunciation of *o* and *a*, whenever these vowels occur at the end of a word; the articles *o* and *a* abbreviated from *lo* and *la*, together with the compounds formed from them, as *no* and *na* instead of *en lo* and *en la*; and the loss of that sonorous accentuation of the Spanish words by the change of *color*, *palazio*, *padre*, *madre*, &c. into *cor*, *paço*, *pay*, *may*, if they add in some manner to the fluency of the Portuguese, place it far beneath the stateliness and majesty of the Spanish. Sismondi has very wittily remarked that the Portuguese was only *un Castillan desossé* (a boneless Castilian). The *j* and the *ch* are the two sounds in which the Portuguese differs most from the Spanish; these letters are pronounced like the French, whom they also imitate in some nasal sounds, and in their mute endings. The best Portuguese grammar is that of Pedro Jozé de Figuereido ('Arte da Grammatica Portugueza,' Lisboa, 1799); and the best dictionary the revised edition of Bluteau, by Antonio de Moraes Silva, Lisboa, 1739, 2 vols. 4to. In 1793 the Academia Real das Sciencias of Lisbon undertook to publish a Portuguese dictionary, of which however only one volume has hitherto appeared, a thick folio, containing A, and embracing the fifth part of the words in the language.

Literature.—The literature of Portugal is complete without being very rich. In all branches there have been happy attempts; in none is there an abundance, except in lyric and bucolic poetry, in both which branches the Portuguese are richer than their neighbours of the Peninsula. Poetry comprises the most important part of their literature; prose and eloquence have been very little cultivated, owing to the intolerance of the government and the persecutions of the Inquisition. After the fifteenth century, poetry in Portugal became and remained bombastic and affected, and its antient power and natural grace were completely lost. In the time of Louis XIV. the French were copied, and many Gallicisms were admitted. Under Pombal, Portuguese literature revived, and poets strove to give elevation to the language. Prose too became more simple and pure by the imitation of the classics. That minister was the first who banished the scholastic logic and metaphysics from the lecture-rooms of Coimbra. The study of the antient languages was always and still continues to be neglected. There are not more than eight schools for the Greek language in all Portugal.

That Portuguese poetry flourished earlier than the Castilian is generally supposed from the fact of two poets, Gonzalo Hermiguez and Egaz Moñiz, having written in verse as early as the reign of Alfonso I., in the twelfth century. The few poetical fragments however of these antient bards which have been preserved by Faria e Sousa (*Europa Portugueza*, vol. iii., p. 378) are not wholly intelligible even to natives of Portugal. As no Spanish verses of that age by any known author are extant, the opinion entertained by Bouterwek (vol. ii., p. 3) that the prevailing tone of romantic love which characterised the poetry of the Spaniards and Portuguese, until the imitation of the Italian style was generally adopted, originated in Portugal, is not without foundation; although the supposition is rendered less probable by the fact that the Galician and Portuguese languages and poetry were originally, and even long after the separation of Portugal from the Castiles, scarcely distinguishable. In the same manner we might be inclined to think that the Portuguese also preceded the Spaniards in epic (or rather, historical) poetry, since an old Portuguese narrative in dactylic stanzas, quoted by Faria e Sousa, is unquestionably much older than any similar attempt of the Castilian poets. However, until the latter half of the thirteenth century, when the language became more regular and distinct, the rude attempts of the early poets of Portugal cannot be mentioned otherwise than as curious relics of antient times. King Dinis, who, like his contemporary Alfonso the Learned of Castile, was a poet and a prose writer himself, was the first to improve poetry and give an impulse to general literature. His poetical compositions were, according to the fashion of the age, collected in *cancioneiros*, which bore the name of the royal author. Under Alfonso IV., the son of Dinis, the taste for poetry increased. His verses however have never been printed, nor have those of Alfonso Sanchez, a natural son of Dinis. Pedro I., better known to English readers for his unfortunate connection with the beautiful Inés de Castro, wrote a poem in the Castilian language, in addition to some compositions in Portuguese. The Infante Dom Pedro, son of Joam I., is supposed to have translated some of Petrarch's sonnets. With the fifteenth century begins the flourishing period of Portuguese literature. A tender as well as heroic spirit, a fiery activity, a soft enthusiasm, war, love, and glory filled the whole nation; and the Portuguese poets sang in an heroic and romantic strain, of which the 'Cancioneiros Geraes' contain numerous specimens. The earliest of these was printed in 1516, by Garcia de Resende, who lived at the courts of Joam II. and Emmanuel the Great. A later collection, by Pedro Ribeyro, bearing the date of 1577, is still in manuscript. Another, discovered at Madrid, in 1790, by Joaquim Jossé Ferreira Gordo, comprising poems by a hundred and fifty writers of the fifteenth century, is known only by a short account of it in the 'Memorias da Litteratura Portugueza.' Bernardim Ribeyro, who flourished under Emmanuel the Great, and who is better known as the author of a romance in prose entitled 'Menina e Moça' (Lisboa, 1559 and 1785, 8vo.), was the first to write eclogues, which, when compared with those of Juan de la Encina, a Castilian poet, his contemporary, may in every respect claim superiority. This direction of taste gave rise to the numerous pastoral poets of Portugal during the fifteenth century. Christovão Falcão, a knight of the order of Christ, and governor of Madeira, was the author of a long eclogue of 900 verses, which was printed as an appendix to the works of Ribeyro. Several eminent poets imitated his example; and Portugal has not without reason been regarded as the native land of romantic pastoral poetry, which the Portuguese poet Jorge de Montemayor afterwards introduced into the literature of Spain. It is a remarkable fact that several distinguished poets of that age composed indifferently in the Portuguese and Castilian languages, but used the latter in preference, if they wished to treat great subjects. Saa de Miranda, who flourished towards the middle of the sixteenth century, and is the author of several eclogues and pastoral romances, besides two comedies and several epistles in imitation of those of Horace, is considered to be the introducer of the Italian style of poetry into Portugal, where it was quietly adopted, and without exciting the violent literary storm raised in Spain against its partisans. He was also the founder of a classical school, which was not without admirers and imitators. In this number may be enumerated Antonio Ferreyra, whom the Portuguese call their Horace, owing to his having successfully imitated that author's epistles, and whose works were reprinted in 1772 at Lisbon; Jeronymo Cortereal, the author of an epic poem entitled 'La Batalla de Lepanto,' and several other works in Spanish; Diego Bernaldez, who wrote eclogues, epistles, and numerous sonnets; and, lastly, Pedro de Andrade Caminha, whose long-lost works were discovered and printed at the expense of the Royal Academy of Lisbon in 1791, 8vo. The most celebrated however of all the Portuguese poets is Luys de Camoens, whose poem 'Os Lusiadas' is sufficiently known, and has been translated into almost every language of Europe. There are no less than three English versions of it: the most antient is that of Richard Fanshaw (Lond., 1655, fol.); next comes that of William Julius Mickle, which appeared at Oxford in 1776, 4to.; and lastly that of Thomas Moore Musgrave, 1826, 8vo.

Soon after the death of Camoens, who ended his life in an hospital in the year 1579, the learned Rodriguez Lobo Surupita published the first collection of his hitherto scattered poems. Manoel de Faria e Sousa afterwards published a learned Spanish commentary on the works of the Portuguese poet, Lisbon, 1685-9, fol. A very handsome edition was lately produced by Jozé Maria de Souza Botelho, and printed at Paris by Firmin Didot, 1817, 4to. Jorge Ferreira de Vasconcelos distinguished himself by the composition of several comedies. He was also the author of a new 'Romance of the Round Table.' Estevam Rodriguez de Castro, a poet, and at the same time a learned physician, wrote sonnets, odes, and eclogues with great success. Fernando Rodriguez Lobo de Surupita, who edited the miscellaneous poems of Camoens (Lisbon, 1595), likewise belongs to this age. Besides his juridical works, he was the author of various humorous pieces in verse. About this time antient literature seems to have had a powerful influence on the education of the Portuguese nobility. The learned statesman Miguel Cabedo de Vasconcelos, who resided for several years in France, was particularly distinguished as a writer of Latin verse; and the celebrated Rodriguez Lobo, who must not be confounded with Lobo Surupita, the editor of Camoens' works, made several successful attempts to introduce a kind of Ciceronian style into Portuguese prose. His 'Corte na Aldea, e Noites de Inverno' is a species of romance in prose, in which he not only imitated the style of the Roman orator, but introduced dialogues with the same forms of friendly intercourse as those which characterise the Tusculan and Academic Discourses, in which friends discourse concerning the proper education of an accomplished man of the world. This production, which must be considered as the first Portuguese classical prose work, did not prevent the author from cultivating poetry, and his pastoral romances are the most luxuriant blossoms of this old branch of Portuguese literature.

In this century also, the voyages of discovery of the Portuguese, and the travels of their missionaries, furnished abundant literary materials. Of this kind are the 'Perigrinaçam' (Travels), by Fernam Mendes Pinto (Lisboa, 1620, fol.), which were translated into almost every European language; the 'Itinerary through Persia and India' by Teixeira; the 'History of Tangiers' by Menezes; and the accounts of the missions to Abyssinia and Ethiopia, by Almeida, Alvares, and others. Romances and books of chivalry are another branch of literature which the Portuguese diligently cultivated during the sixteenth century. The former they imitated from the Spaniards, to whose language—the Castilian—this kind of composition seems to be essentially attached; but they claim, not without reason, the priority in the second. 'Palmerin de Oliva,' which, next to 'Amadis of Gaul,' Cervantes spares in his judgment on romances of chivalry, was written by Francisco de Moraes; and there is every reason to believe that 'Amadis,' in its original form, is also the production of a Portuguese writer; of the same sort are, 'As Ribeiras de Mondego,' by Saa Sotomayor, 'A Constante Florinda,' by Gaspar Pires de Rebello, the author of some short didactic novels, and many others which are mentioned by Barbosa Machado and *other* bibliographers.

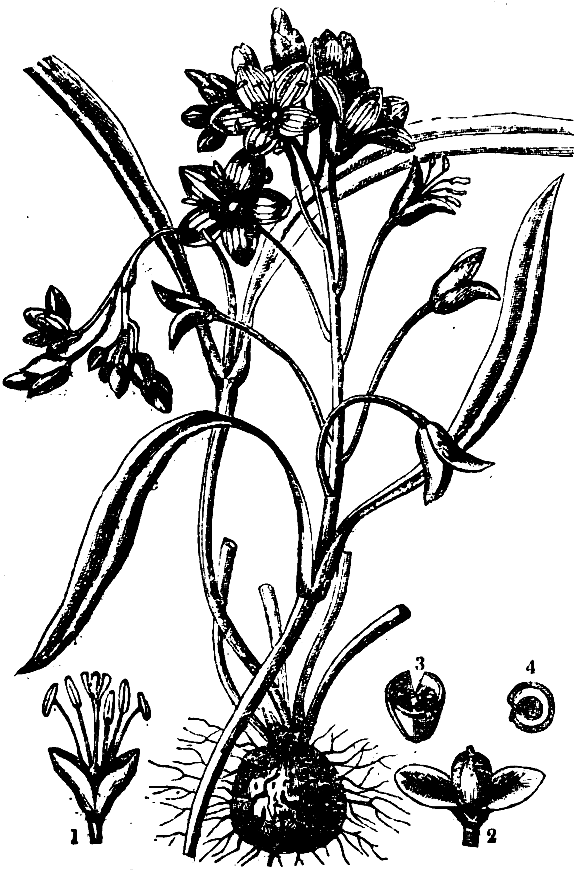
At no period did historical composition in Portugal attain the elevation which it reached in Spain; the antient chronicles are fewer, and not so well written; there is little or no local history, and as to a general narrative embracing all the events and political transactions of that kingdom, the Portuguese possess none but the incomplete work of Brito. As might be expected, the events of India formed the favourite theme of many of the Portuguese historians of the sixteenth century. At the head of these stands João de Barros, whom the Portuguese have called their Livy, and whose historical labours well deserve an ample notice in a review of Portuguese literature. He was born at the beginning of the sixteenth century, and died in the year 1570, at the age of seventy-four. Having been appointed by King John III. to the post of treasurer to the Indian department, he devoted his whole life to collect materials for his great historical work, which he divided into Decades, and published under the following title, 'Asia de João de Barros, dos feitos que os Portuguezes fizeram no descobrimento e conquista dos mares e terras de Oriente,' Lisboa, 1553. Barros left only three decades, but Diogo do Couto, who succeeded him in his office, wrote the seven remaining, five of which were printed at Lisbon, and two, still inedited, are preserved in manuscript in the library of the British Museum. [BARROS.] Nearly contemporily with Barros lived Lopez de Castanheda, the author of another history of the discovery and conquest of India by the Portuguese, the first edition of which appeared at Coimbra in 1552-61. This work was reprinted at Lisbon in 1797, with the old orthography. A diffuse Chronicle of King Emmanuel, published about the same time by Damião de Goes, is more valuable for the facts which it contains than for the style. The Life of the great Affonso d'Albuquerque, composed by his son, is highly esteemed by the Portuguese. The language is pure, but the style, which is that of the old chronicles, is monotonous and very diffuse. Bernardo de Brito, a monk who flourished towards the latter end of the sixteenth century, attained a higher degree of historical excellence. He was educated at Rome, where he seems to have early conceived the idea of writing a complete history of his native country. On his return to Portugal he entered the convent of Alcobaça, and began his arduous task, but he died in 1617, in the forty-seventh year of his age, without having accomplished the object to which he honourably aspired. The two volumes of his work entitled 'Monarchia Lusitana,' which contain only the antient history of Portugal, were printed, the first at the convent of Alcobaça, in 1597, the second at Lisbon, in 1609. Brito was likewise the author of a smaller historical work entitled 'Elogios dos Reys de Portugal.' Much that is really valuable for the early history of Portugal may be gathered from the collection entitled 'España sagrada,' Mad., 1754-1801, by Father Enrique Florez, who published the 'Cronicon Lusitanum' and 'Chronicon Conimbricense.' The other historians of Portugal who ought to be consulted are, La Clède, 'Histoire Générale de Portugal,' Paris, 1735, 2 vols. 4to.; Brandão, 'Monarchia Lusitana,' Lisboa, 1675-72; Lemos, 'Historia geral de Portugal e suas conquistas,' Lisboa, 1786-1804, 20 vols. 8vo.; Vasconcelos, 'Anacephalæosis Actorum Regum Lusitaniæ,' Antwerp, 1621; and lately, the 'History of Spain and Portugal,' in Dr. Lardner's 'Cabinet Cyclopædia.'

The origin of the Portuguese theatre is hid in darkness The Portuguese Gil Vicente was a contemporary of the Spanish Torres Naharro, and the dramatic compositions of the Portuguese poet so far approximate to the ruder comedies of the Spaniard, as to entitle the Portuguese to claim for their own country the honour of the invention. Gil Vicente was really the father of the Portuguese theatre, and his plays, though no longer acted, are still read by people of taste. The edition of his works which his son published soon after his death, contains, in addition to sixteen *autos*, or spiritual dramas, three tragi-comedies, some *farsas*, and a few dramatised novels, which are called *comedias*. In all these productions Gil Vicente exhibits much dramatic invention and a true poetic genius. It is said of Erasmus that he learned Portuguese for the express purpose of reading Gil Vicente's plays in the original, but though Gil Vicente is undoubtedly the father of the Portuguese drama, its history cannot be said to commence until the time of Saa de Miranda, the first dramatic author who composed dramas similar to the Spanish. His two chief productions however, 'Os Estrangeiros' (the foreigners), and 'Os Vilhalpandos' (so called from two Spanish soldiers who had both adopted the name of Vilhalpando), are dramas in the style of Plautus and Terence, of whom he avowed himself an imitator. Ferreira, who lived after Saa de Miranda, not only followed in his steps, but laboured, though ineffectually, to introduce into the dramatic poetry of Portugal a classical style. His tragedy of 'Inés de Castro,' though deficient in true pathos, contains many beautiful passages. His two comedies, 'Bristo' ('Comedia do Bristo') and the 'Jealous Man' ('Comedia do Cioso'), resemble in spirit and form those of Saa de Miranda. Three dramas by Camoens, 'El Rey Seleuco,' 'Os Amphytryoes,' and 'Filodemo,' are more remarkable for beauty of style than for invention. Dramatic invention and composition long wavered amidst heterogeneous forms, until the Portuguese poets, who wished to write for the theatre, had no alternative but to become the imitators of Lope and the dramatic authors of his age, and to renounce entirely the formation of a nationaldrama. This in fact took place. During the seventeenth and eighteenth centuries the Portuguese stage was inundated with translations of Spanish dramas, and all hopes were lost of re-establishing the national drama.

With the sixteenth century the brilliant period of Portuguese literature passed away, and the connection with Spain and the influence produced at the beginning of the seventeenth century by the fantastic school of the Gongoristas [GONGORA] almost entirely naturalised Spanish literature in Portugal. Thus the names of Manoel Faria e Sousa, who died in 1649, and was the author of many works in verse and prose; of Jacinto Cordeiro, a dramatic writer of some eminence; of Barbosa Bacellar, the author of several poetical works printed at Lisbon in 1716; of Manoel Severim de Faria, who wrote some political essays, and many more eminent authors, belong to the history of Spanish rather than to that of Portuguese literature. The restoration of the independence of Portugal, though it called forth fresh displays of patriotism, had no influence on the literature of the country, which continued during the rest of the seventeenth and the greater part of the eighteenth century to follow the traces of the Spanish. Though the Academia Real das Sciencias of Lisbon, founded by king Jozé Emmanuel in 1714, did much towards rousing the nation from its lethargy, and directing attention to the cultivation of science, it was not till the time of Pombal, who himself was a great friend to scientific pursuits, that Portuguese literature revived and acquired a national tone. Francisco Xavier de Menezes, Conde da Ericeyra, the first president of the Academia Portugueza, translated Boileau's 'Art Poetique' into Portuguese octaves, and published, among other writings, an epic poem entitled 'La Henriqueida,' on the foundation of the Portuguese monarchy by Henry of Burgundy, in which he endeavoured as far as possible to fulfil all the conditions of poetic art according to the principles of the French critics. This poem was printed for the first time at Lisbon in 1741, 4to. Contemporaneously with Ericeyra lived Antonio de Lima Barros Pereira, who in 1720, published several religious and other pieces under the title of 'Floresta Appollinea.' Another poet, named Alexandro Antonio de Lima, published in 1740 his 'Rasgos Metricos,' being a collection of poems on various subjects, chiefly written in the Spanish language. Manoel da Costa, a Brazilian, whose complete works were published at Coimbra in 1768, 8vo., was celebrated for his eclogues and *epicedios* or elegies. He was likewise the author of several songs. About the middle of the same century an author, generally called O Judeo, because he was a Jew, displayed great talent in the composition of Portuguese operas. His 'Don Quixote,' which was represented in 1733, and his 'Esopaida, or the Life of Æsop,' may be put on a level with the best operas of Metastasio. Another poet, named Garção, whose poetical works appeared at Lisbon in 1778, 8vo., contributed to the diffusion of good taste. About the same time the desire to cultivate a correct style in Portuguese poetry was fostered by new translations of some of the Latin classics. The 'Odes' of Horace were elegantly translated into Portuguese verse by Joaquim Jozé da Costa e Sá (Lisboa, 1781); the 'Satires' of Sulpitia, by Antonio Luis de Azevedo (Lisboa, 1786); Ovid's 'Heroides,' by Miguel de Couto Guerreiro (Lisboa, 1789); and the 'Comedies' of Terence, by Leonel da Costa (Lisboa, 1788). Paulino Cabral de Vasconcellos must also be named among the Portuguese poets who at the close of the eighteenth century corrected the national taste and subjected it to classical rules. The collection of his poems printed at Oporto, in 1786, in 8vo, contains two hundred and forty-five sonnets, which are greatly admired. Doña Catharina de Sousa wrote a tragedy called 'Osmia,' which was crowned by the Academy. The subject is chosen from the antient history of Portugal, and although when acted upon the Lisbon stage it did not meet with a favourable reception, Portuguese critics look upon 'Osmia' as the best tragedy in their language. The names of Francisco Diaz Gomez, Francisco Cardoso, Alvarez de Nobrega, Xavier de Matos, Valladares, and Nicolao Tolentino, occupy a prominent place among the modern poets of Portugal. Francisco Manoel, who was born in 1734, and was long confined in the dungeons of the Inquisition, published, in 1808, at Paris, a volume of lyric poems. José Basilio de Gama wrote a poem on the conquest of Paraguay, which is very much esteemed. Manoel Maria de Barboza du Bocage is also counted among the popular poets of Portugal. Of his 'Rimas,' the second edition appeared at Lisbon in 1800; and the third, in 1804, under the title of 'Poesias,' dedicated to the Countess of Oyenhaussen. This lady, a daughter of the Marquis of Alorno, is said to have made a Portuguese translation of Wieland's 'Oberon.' Araujo de Azevedo, a distinguished statesman, is the author of several excellent translations such as Dryden's 'Alexander's Feast,' some of Gray's 'Odes,' and the 'Elegy in a Country Church-yard.' Jozé Monteiro de Rocha and Mozinho d'Alboquerque are also esteemed good poets. Prose-writing however was far from keeping pace with these poetical effusions. With the exception of Barbosa Machado's 'Biographical Dictionary of Portuguese Authors,' written in imitation of Nicolas Antonio's 'Bibliotheca Nova et Vetus,' which is a valuable work, scarcely an historical or literary composition appeared in Portugal in the eighteenth century. A few years since, Padre Antonio Moura published a Portuguese translation of a history of Africa entitled 'Al Kartas,' written about the middle of the fourteenth century by a Moor of Granada. The same writer is now publishing a translation of the original travels of Ibn Battutta, an Arabian writer of the fourteenth century, the first volume of which has just appeared at Lisbon in 4to. Since 1827, a Portuguese periodical has been published in Paris, called 'Novos Annaes das Sciencias e das Artes,' in which a fragment of a great Portuguese poem yet in manuscript, 'Branca ó la Conquista de Algarve,' has been printed. A monthly Review has likewise been lately started at Oporto. Scientific studies, especially mathematics and natural history, if not entirely uncultivated, attract little attention. According to Balbi, among the three millions of Portuguese there are hardly five hundred readers of scientific books. The only comprehensive history of Portuguese literature in any European language is that of Frederick Bouterwek; this work, which comprises also the history of Spanish literature, was translated into English by Miss Ross (Lond., 1823, 8vo.). But Bouterwek's work, in the opinion of critics, is far from being either complete or accurate. Sismondi, in his 'Littérature du Midi del' Europe' (vol. iv.), has done little else than copy the German author. A short history of the Portuguese language and literature may also be found in the preface of Joaquim de Santa Rosa Viterbo to his 'Elucidação das Palabras, Termos, e Frases que em Portugal antiguamente se usarão,' &c., Lisboa, 1798, 2 vols. 8vo.

Those who wish to get an insight into Portuguese literature may consult Barbosa Machado, *Bibliotheca Lusitana*, Lisboa, 1741-59, 4 vols. fol.; Faria e Sousa, *Europa Portugueza*, Lisboa, 1678-80, 3 vols. fol.; Velasquez, *Origines de la Poesia Castellana*, Malaga, 1754, 4to., and Dieze's Remarks upon that work; Sarmiento, *Obras Posthumas*, Madrid, 1775, 4to.; but above all, the *Memorias de Litteratura*, published by the Royal Academy of Sciences in Lisbon, 1792-1836, 4to., and the *Catologo dos Livros, que se hão de ler para a Continuação do Diccionario da Lingua Portugueza*, a work which appeared in 1792 by order of the same Academy.

PORTULA'CEÆ, a small natural order of polypetalous Exogens with hypogynous stamens; distinctly characterised by having two sepals, five petals, and a central placenta, whose seeds contain a curved embryo, lying upon mealy albumen. Their fruit is commonly one-celled, but the edges of the carpels are sometimes so much inflected as to press upon the placenta and divide the interior into cells. They are annual, perennial, half-shrubby or shrubby plants, with entire more or less succulent leaves, rarely furnished with stipules, and with flowers which are often very showy, although more frequently inconspicuous. Their prevailing colour is purple or scarlet. They occur in all the hotter or milder parts of the world, especially in dry exposed situations, for which their succulent leaves render them well-suited; the Cape of Good Hope is their favourite station.



Portulaceæ. A plant of Claytonia virginica.

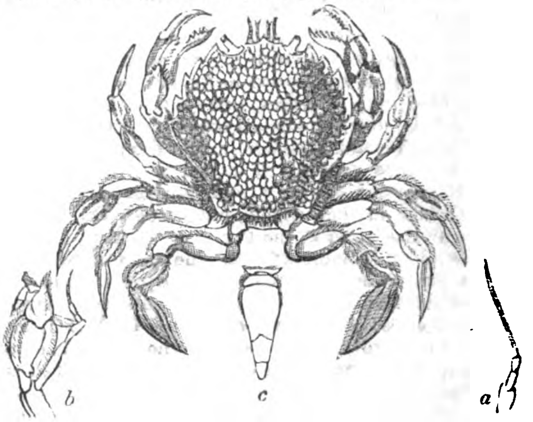
1, Calyx, stamens, and pistil; 2, capsule, with the two permanent sepals; 3, a transverse section of a capsule; 4, a vertical section of a seed.

Common Purslane, *Portulaca oleracea*, a potherb, now disused, indicates the harmless quality of such plants. The Tulinums and Calandrinias and a few species of Portulaca are well known as gay garden-flowers.

PORTUMNUS, Dr. Leach's name for a genus of *Brachyurous Crustaceans*.

Generic Character.—External antennæ setaceous, very short, having their two first joints larger than the others, inserted at the internal canthus of the eyes. *External jaw-feet* having the third joint of their internal branch elongated, nearly conical and notched internally. First pair of *feet* large, equal, with the fingers of their pincers rather long. Fifth pair of feet terminated by a flattened foliaceous and nearly lanceolate joint. Carapace rather flat above, with the anterior border arched and semicircular, and the posterior border nearly truncated, having its longitudinal diameter equal to the transversal diameter; *orbits* without fissures, *eyes* moderate.

Example, *Portumnus variegatus*. *Locality.*—The Adriatic Sea, the Mediterranean, and the ocean.



Portumnus variegatus, male.

a, external antenna; *b*, external jaw-foot; *c*, tail or abdomen.

The species above figured appears to be identical with *Platyonychus latipes* of Milne Edwards; nor does there appear to be any sufficient reason for distinguishing the form generically from *Platyonychus*. [PORTUNIDÆ.]

PORTU'NIDÆ, or *Paddling Crabs*, a family of *Brachyurous Crustaceans*, nearly allied to the *Cancerians*.

M. Milne Edwards makes the *Portunians* the second tribe of the family of *Cyclometopes*, observing that it nearly corresponds to the genus *Portunus*, as it was established by Fabricius, and comprehends the greater part of the crustaceans which Latreille arranged in his division of *Brachyures nageurs* (*Swimming Brachyura*). M. Milne Edwards is of opinion that the closest analogy unites these animals to the Cancerians, from which they are hardly to be distinguished except by the peculiar conformation of their posterior feet; a character of much importance, inasmuch as it influences their manner of life, but which is found in a manner more or less marked in the species belonging to the greater part of the other natural groups of the section *Brachyura*.

The general form of the *Portunians*, says M. Milne Edwards in continuation, does not ordinarily differ much from that of the greater part of the *Cancerians*, but the *carapace* is always but little elevated, and sometimes has a lozenge-shape. The orbits are directed upwards and forwards. The *internal antennæ* are bent back transversely, or at least very obliquely outwards, and the basilary joint of the *external antennæ* is partially lodged in a gap of the internal orbitary angle. The third joint of the *external jaw-feet* is always wider than it is long, and sharply truncated or notched at its anterior and external angle for the insertion of the fourth joint.

Orbits, antennæ, jaw-foot, &c., of Portunus.

The *sternal* plastron is always very wide, and in general the last thoracic segment is much more developed than all the others, even than that which carries the anterior feet; the suture which separates this segment from the preceding is directed very obliquely forwards and inwards; the vault of the sides is generally nearly horizontal, and the posterior *sella Turcica* very narrow. The anterior *feet* are in general very elongated, the succeeding feet are sometimes natatory, and the posterior feet always so, their tarsus being lamellar: the second pair of feet are ordinarily more than once and a half as long as the carapace.

Habits of the Tribe.—The crustaceans of this group are for the most part essentially swimmers, and live often out at sea. They are vulgarly called *Puddlers.* The following genera are arranged under the tribe by M. Milne Edwards.

Carcinus. (Leach.)

Generic Character.—Carapace approaching in general form that of *Panopeus*, but little convex, although sufficiently elevated, and remarkably wider than it is long. The latero-anterior borders, which are deeply dentated, form with the orbital border a regular curvature which does not reach beyond the level of the middle of the genital region; latero-posterior borders very long and moderately oblique. The branchial regions very much developed and rounded anteriorly. Front advanced, horizontal, of moderate width. Orbits oval and directed forwards; there is a fissure at their upper border and one at their lower border; the gap at their internal angle lodges the base of the external antenna, the first joint of which is narrow and cylindrical, and reaches to the front; their moveable stem is very long and inserted in the orbital gap. The internal antennæ are bent back in their nearly circular fossets obliquely outwards. The buccal frame is a little wider backwards than it is in front, and the third joint of the jaw-feet is much dilated externally, and notched at its two internal angles. The *sternal plastron* is similar to that of the *Portuni*, and so would be the feet, if it were not that the tarsus of the posterior feet is not much enlarged, and is of a flattened lanceolate form, though narrow, whilst that of the preceding feet is styliform. The abdomen of the male is only composed of five segments. (M. E.)

Example, *Carcinus Mænas*, *Cancer Mænas* of authors, *Crâbe enragé* of the inhabitants of the coast of Normandy, *The small common Crab* hawked about London and eaten by the poorer classes. Length rather more than two inches.

Feet of Carcinus.

Locality, Habits, &c.—Very common on the coasts of England and France, where it is found at low tide between stones and buried in the sand. This species runs on the beach with rapidity, and can sustain a long absence from the water. It is edible, though not much used as an article of food in England; but, during the summer, a great many are brought to Paris. Colour, dirty green; red when boiled.

Platyonychus. (Latr).

Generic Character.—Carapace narrower and more regularly convex than that of the other Portunians, often much longer than it is wide, and sometimes circular. Front very narrow and dentated. Latero-anterior borders a little curved and directed backwards, and, like those of the *Carcini*, the *Polybii*, and the greater portion of the *Portuni*, divided into five teeth. Orbits not deep, and directed forwards. Internal antennæ bent back obliquely forwards, with their fossets very imperfectly separated from the orbits. Disposition of the external antennæ different from that in the *Carcini*, the *Portuni*, the *Thalamitæ*, and the *Lupeæ;* their first joint, which is very small, is not soldered to the front, but is moveable, like the succeeding ones, and is inserted between the lower orbital border and the antennary fosset. The external jaw-feet present nothing remarkable, except in their third joint, which is narrower than in the greater part of the *Portuni*, and advances obliquely to the nucleus of the antennary fossets. Sternal plastron oval, narrow, and very much narrowed posteriorly, and, as in the *Portuni*, its median suture occupies only the two last segments. The anterior feet are moderate and not very unequal; they are applied exactly against the buccal region, and entirely resemble those of the *Portuni;* the second pair of feet are rather long, and have the tarsus flattened, a little enlarged, and of nearly a lanceolate form; the tarsus of the succeeding feet is also a little flattened, but rather styliform than lamellar; the fifth pair completely natatory. (M. E.)

M. Milne Edwards divides the genus into the following sections and subsections:—

α.

Species having the frontal teeth unequal in number, one of them occupying the median line, and a single fissure at the superior orbital border.

a. Tarsi of the posterior feet of lanceolate form.

Example, *Platyonychus latipes* (*Cancer latipes*, Penn.; *Portumnus variegatus*, Leach (*Malac.*); *Platyonychus depurator*, Latr.). Length about an inch. *Locality*—Coasts of England and France. [Portumnus.]

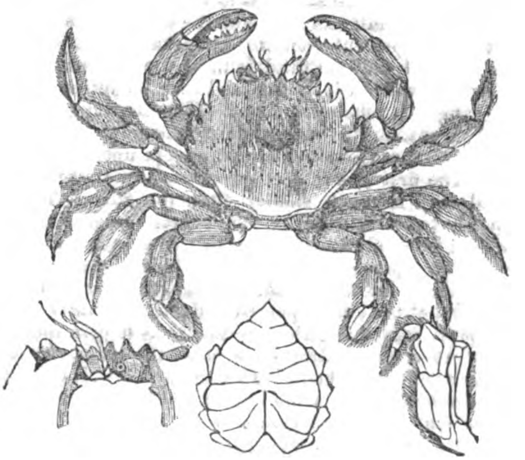
a a. Tarsi of the posterior feet oval and obtuse at the end.

Example, *Platyonychus ocellatus* (*Cancer ocellatus*, Herbst; *Portunus pictus*, Say; *Platyonychus oscellatus*, Latr.). Length about two inches.

β.

Species having the frontal teeth equal, and consequently not one on the median line, and two fissures at the superior orbital border.

Example, *Platyonychus bipustulatus.* Length from two to five inches. *Locality*—Indian Ocean.



Platyonychus bipustulatus.

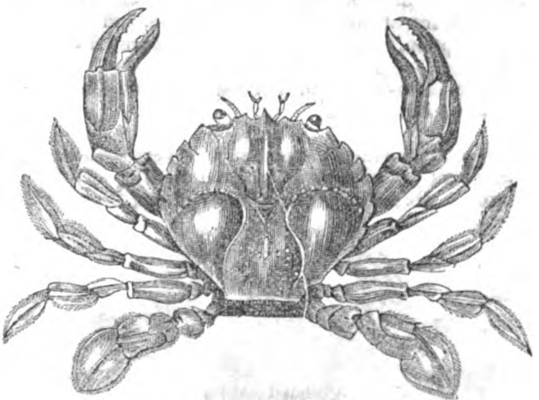
γ.

Species having the front advanced in form of a triangular muzzle and simply undulated on its borders.

Example, *Platyonychus nasutus* (*Portunus biguttatus*, Risso, *Crust. Nice.*) very small. *Locality*—The coasts of the Mediterranean.

Polybius. (Leach.)

Generic Character.—Very nearly allied to *Platyonychus*, from which it hardly differs, except in the form of the feet, which are all natatory; those of the second, third, and fourth pairs are very much flattened, and terminated by a very large and lanceolate joint, which has the same form throughout. The posterior feet have the same form as those of *Platyonychus bipustulatus*, excepting that their third joint is extremely short and nearly globular. The sternal plastron is wider, especially posteriorly, than in *Platyonychus*, but presents the same disposition as to the median suture. The abdomen of the male has the ordinary number (five) of joints. (M. E.)



Polybius Henslowii.

Example, *Polybius Henslowii.* Length about two inches: colour brown. *Locality*—The British Channel, where it appears to haunt at a distance from the coast.

Portunus. (Fabr.)

Generic Character, as restricted by M. Milne Edwards.—Carapace nearly of the same form as in *Carcinus*, wider than it is long, but with its longitudinal diameter at least equal to two-thirds of its transversal diameter, and the contour of its anterior portion ordinarily more curved than it is in that genus. The fronto-orbital border occupies hardly more than the half of the transversal diameter of the carapace, and the front, which is narrow, advances always much beyond the insertion of the external antennæ, and reaches in a remarkable manner beyond the level of the inferior border of the orbit, and the external angle of this cavity. The latero-anterior border of the carapace is delicate and armed with four or five large teeth; the orbits are oval. The antennary fossets are placed on the same level with the eyes, are transversal, and are separated from each other by a partition, the border of which is never prolonged into the form of a spine. The basilary joint of the external antennæ is but little developed, but completely separates the antennary fosset from the orbit, and is soldered to the front; the moveable stem which succeeds to this joint would seem to spring from the internal angle of the orbit. The structure of the mouth presents nothing remarkable, but it is to be borne in mind that the third joint of the external jaw-feet is at least as wide as it is long, and that its anterior and internal angle is much truncated. The sternal plastron is much longer than it is wide, and much narrowed backwards; its median suture is not extended, except upon the last two rings. The first pair of feet are of moderate size, and, in general, one is much stouter than the other. The arm reaches but very little beyond the lateral border of the carapace, and is not always armed with spines as in *Lupea;* the carpus always presents on its internal side a great spiniform prolongation, and the hand, the length of which never equals that of the antero-posterior diameter of the carapace, is ordinarily moved a little inwards, so as to give the capability of an exact application against the anterior and inferior portion of the body. The three succeeding pairs of feet are nearly of the same length; but, nevertheless, the third or fourth pair are generally longest, and the second are shorter than the anterior pair; their last joint is styliform and canaliculate. The fifth pair are, on the contrary, very much enlarged at the end; their third joint is nearly of the same form as the preceding ones, and their last joint is lamellar, and oval or lanceolate. The abdomen presents nothing remarkable, its disposition being nearly the same as in the preceding genera, except that it is less wide in the females and is always triangular in the males. The genus, as restricted, establishes the passage between the *Carcini* on one side and the *Lupeæ* on the other. (M. E.)

Habits, Locality, &c.—The *Portuni,* though essentially aquatic and swimming with much ease, are not met with far out at sea like the *Lupeæ.* Their haunts are near the shore, and at spring-tides they are often found during the ebb hidden under stones, in the small pools of water left by the sea. Some species inhabit still greater depths, on oyster-beds, &c., and they are never seen to run, like the *Carcini,* on the shore. When withdrawn from the water, they perish in a few hours. They are eminently carnivorous, feeding mostly on the dead bodies of animals which they find in the sea. Many of the species are eatable, and all, with a single exception, inhabit the coasts of England and France. (M. E.)

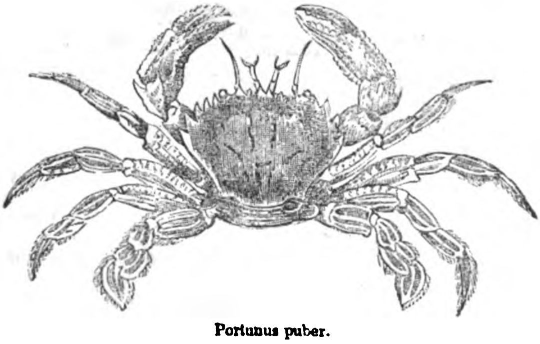
M. Milne Edwards divides the species into the following sections and subsections.

α.

Species having the front armed with very distinct teeth.

a. Front armed with at least ten teeth or spines.

Example, *Portunus puber* (*Cancer puber,* Linn.; *Cancer velutinus,* Penn.). Length about two inches and a half. *Locality*—The coasts of England and France. This is the *Crâbe à laine, Crâbe Espagnol,* &c., of the French.



Portunus puber.

aa. Front armed with three or five teeth.

*aa**. Carapace wrinkled, unequal, rather granulous, and covered with hair.

Example, *Portunus plicatus* (*Cancer Depurator,* var. Penn.; *Portunus Depurator,* Leach; *Portunus lividus* (var.?), Leach, *Malac.*). Length about eighteen lines. Colour reddish. *Locality*—Coasts of England and France.

*aa***. Carapace nearly united, and without hairs.

Example, *Portunus marmoreus* (*Cancer Depurator,* Penn.). *Locality*—Coasts of England and France. The last joint of the posterior feet in this species terminates in a point.

β.

Species having the front entire or divided only into rounded lobes.

b. Latero-anterior borders of the carapace armed with five teeth.

*b.** Front divided into three lobes, of which the median lobe is more advanced than the lateral lobes.

Example, *Portunus corrugatus* (*Cancer corrugatus,* Penn.; *Portunus puber,* Blainv.). Length about two inches. Colour reddish. *Locality*—Coasts of England and France; very common in the Mediterranean.

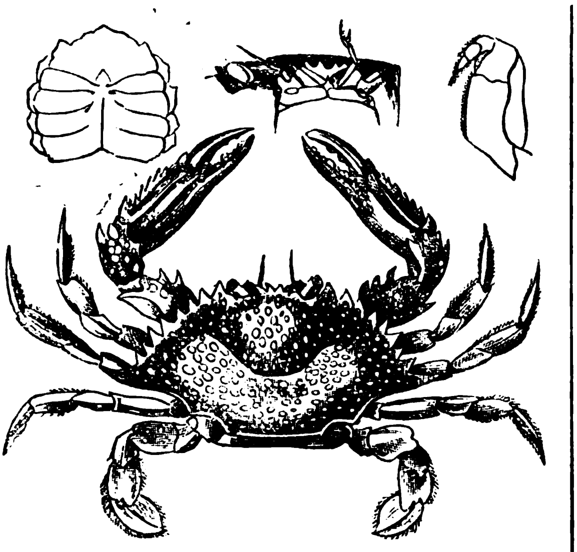
*b***. Front entire, or divided only into two symmetrical lobes.

bb. Latero-anterior borders of the carapace armed with four teeth only.

Example, *Portunus integrifrons* (*Cancer Navigator?* Herbst). Carapace pubescent. Length about two inches. *Locality.*—Indian Ocean.

Lupea. (Leach.)

Generic Character.—The greater part of the *Lupeæ* are remarkable for the flatness and great transversal extent of their *carapace,* the diameter of which in that direction is more than double its length. Front nearly always narrow, and much less projecting than the lower border or external angle of the orbit; the latero-anterior border of the carapace very long, forming generally, with the anterior border, a very regular and open segment of a circle, and each of them armed with nine teeth, more or less projecting and spiniform; of these spines the last is in general much greater than all the others, and is directed straight outwards, though sometimes it does not differ from that which precedes it. Orbits oval, and directed obliquely forwards and upwards; their lower wall does not reach to the front, and there is, at the internal canthus, a large notch, which the basilary joint of the external antenna fills; at the upper border of these cavities are two fissures. The fossets which lodge the internal antennæ are not deep, and hardly covered by the front; the vertical lamina which separates them is armed with a spiniform point, which is often prolonged beyond the anterior border of the carapace. Externally, these cavities are completely separated from the orbits, and the stem of the antennæ, which are there inserted, is sufficiently short to be bent back there entirely. The basilary joint of the external antennæ is soldered to the inferior border of the superior and external angle of the front; it is not wide, and gives insertion, by the extremity of its internal border, to the moveable stem formed by the succeeding joints, so that this stem, the length of which is considerable, would seem to spring from the internal canthus of the eye, and nothing prevents its being bent backward outwards to conceal itself in the orbital cavity. The epistome is extremely narrow, and the buccal frame is very nearly square, but, in general, wider forwards than it is behind. The third joint of the external jaw-feet is rather abruptly truncated forwards and inwards. The sternal plastron is nearly always tolerably convex longitudinally, very wide, and hardly closed (resserré) posteriorly; its median suture occupies the last three segments. The first pair of feet are very large, and always armed with a certain number of spines; the fingers are elongated, and not remarkably curved inwards. The three succeeding pairs of feet are much shorter, and are all nearly of the same size; sometimes their terminal joint is slender, rounded, styliform, and in general canaliculated; sometimes it is flattened, lamellar, and natatory. In the first case the feet would appear to be specially destined for walking, whilst in the second their disposition is more favourable to swimming. The fifth pair are very strong, and constitute, by the width of their last two joints, powerful oars; their third joint (or thigh) is in general stout, but very short, and pre-



Lupea and details.

sents scarcely any spines, as in *Thalamita*. The last joint is always oval. In the female the abdomen presents nothing remarkable, except that its length is very considerable; in the male its structure is the same as in the preceding genera, there being only five distinct pieces, the third, fourth, and fifth rings being soldered together; the first three segments are always very large, but at the level of the fourth there is a sudden narrowing, and the last three are narrower still. (M. E.)

Habits, &c. of the Genus.—The *Lupeæ* are Pelagic Crustaceans, living in the ocean, where they have been seen by many voyagers, and where they have no other apparent place of repose than the floating *fuci*. Their swimming powers are great, and Bosc remarked that they have the faculty of sustaining themselves at the surface of the water in a state of repose, without the execution of any visible movement.

This genus is divided by M. Milne Edwards, who gives the above summary of their habits, into the three following groups:—

AA. Species with the body very thick and convex above; first pair of feet stout, and not much elongated; the hand considerably shorter than the carapace.

Convex Lupeæ.

Example of this first subgenus, *Lupea Tranquebarica* (*Cancer olivaceus*, Herbst; *Cancer serratus ?* Forsk.; *Portunus serratus*, Rüpp.; *Portunus Tranquebaricus*, Fabr.).

This, the largest Portunian known, is six or eight inches in length, of a greyish green, and inhabits the seas of Asia.

A. Species having the body very much compressed; the first pair of feet stout, and but little elongated; the hand remarkably shorter than the carapace. Tarsi of the second, third, and fourth pairs flattened, lamellar, and nearly lanceolate.

Swimming Lupeæ. (Second subgenus.)

* Species having the last lateral spine at least twice as large as the preceding, and the front projecting but little.

a. Median teeth of the front projecting but little, and sometimes hardly visible.

a*. Upper border of the orbit armed with a spine.

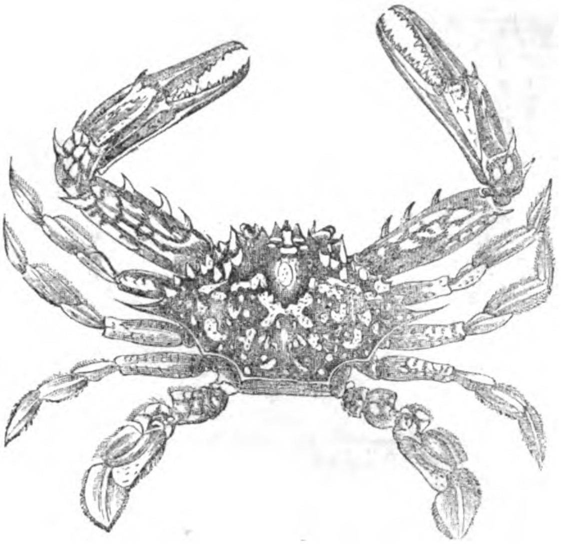
Example, *Lupea pelagica* (*Cancer pelagicus*, Linn.; *Cancer reticulatus*, and *Cancer Cedo Nulli*, Herbst; *Portunus pelagicus*, Fabr.). Length from three to four inches: colour greyish-green with yellow spots. *Locality*—The Red Sea and the whole Indian Ocean.

a**. Upper border of the orbit without any spiniform prolongation.

Example, *Lupea sanguinolenta* (*Cancer sanguinolentus*, Herbst; *Cancer pelagicus, var.* and *Portunus sanguinolentus*, Fabr.). Length about two inches. Carapace with three large bright red spots on the back-part of the carapace. *Locality*—The Indian Ocean.

a***. Median teeth of the front small, but projecting.

Example, *Lupea cribraria* (*Portunus cribrarius*, Lam.). Length three inches; colour yellow, with numerous whitish spots. *Locality*—Coasts of Brazil.



Lupea pelagica.

B. Species having the last spine of the latero-anterior border of the carapace scarcely longer than the others.

b. External border of the arm without spines.

Example, *Lupea spinimana* (*Portunus pelagicus* and *Portunus spinimanus*, Latr.). Length from three to four inches. *Locality*—Coasts of Brazil.

bb. External border of the arms spined.

Example, *Lupea lobifrons*. Length one inch. *Locality*, The East Indies.

C. Tarsi of the second, third, and fourth pair of feet narrow and styliform.

Walking Lupeæ. (Third subgenus.)

a. Species having the last tooth of the latero-anterior border of the carapace resembling the others.

a. Teeth of the latero-anterior borders alternately large and small.

Example, *Lupea rubra* (*Ciri apoa*, Marc.; *Portunus ruber*, Lam.). Length about two inches. General colour reddish; extremity of the claws black. *Locality*—The coasts of Brazil.

a*. Teeth of the latero-anterior borders of the carapace resembling each other.

Example, *Lupea granulata*. Length about an inch. *Locality*—The Isle of France.

b. Species with the last tooth of the latero-anterior border of the carapace at least twice as large as the preceding.

b. Median teeth of the front much more projecting than the lateral teeth.

Example, *Lupea Sebæ* (*Cancer marinus scutiformis*, Seba, *Mus.*, iii., pl. 20, f. 9, copied by Latreille, in *Encycl.*, pl. 272, f. 6, under the name of *Portunus sanguinolentus*. Size about the same as *L. granulata*. *Locality*—Coasts of Brazil. (M. E.)

bb. Median teeth of the front less projecting than the others.

*bb**. Hands large, of the ordinary form, and shorter than the transversal diameter of the carapace.

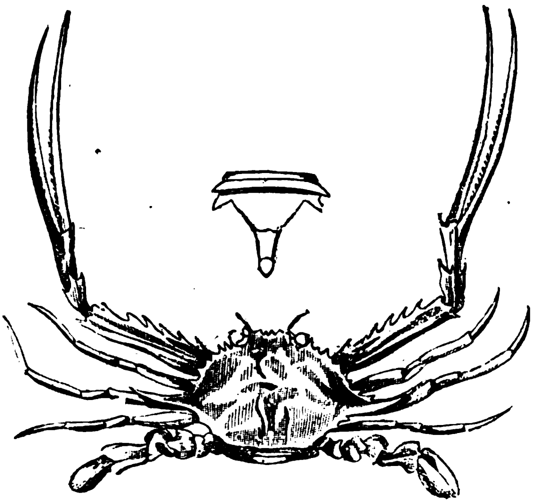
Example, *Lupea hastata* (*Cancer hastatus*, Linn.; *Portunus hastatus*, Latr.; *Lupa Dufourii*, Desm.). Length about two inches. *Locality*—The Mediterranean.

*bb***. Hands filiform and of great length, being nearly once and a half the transversal diameter of the carapace.

Example, *Lupea Forceps*, *Lupa Forceps*, Leach; *Portunus Forceps*, Latr.). Length about an inch. *Locality*—The Antilles.

Thalamita. (Latr.)

Generic Character.—Carapace in most of the species characteristic; but in some it gradually approximates that of the *Lupeæ;* in fact, sometimes it has the form of an elongated square; its transversal diameter is nearly double the length, and its fronto-orbital border forms with the latero-anterior borders a nearly right angle; in other cases it is nearly hexagonal, its six borders form nearly equal angles, and its width only exceeds about half of its length. The front is always very wide, projecting, and at least as much advanced as the inferior border and external angle of the



Lupea Forceps.

orbit, a disposition which is never observable in the *Lupeæ*. The latero-anterior borders of the carapace are more or less oblique, but always form with the fronto-orbital border a very strong marked angle, where there are from four to seven teeth, the last of which is never remarkably larger than the others. The eyes are stout and short; the orbits oval, and completely separated from the antennary fossets; the upper border of the latter presents two small fissures, and their angle is often nearly as distant from the median line as the angle which terminates behind the latero-anterior border. The internal antennæ bend back completely in their fossets; and the inter-antennary partition projects but little. The basilary joint of the external antennæ is in general very wide, and always soldered to the front throughout the whole extent of its anterior border, presenting externally a more or less considerable projection which separates the orbit from the point of articulation of the moveable stem of those appendages, and which is very long, and inserted sometimes very far from the orbital cavity. The epistome is very distinct and of a lozenge-shape. The buccal frame is very wide, and the external jaw-feet are disposed nearly as in the *Portuni*. The sternal plastron is very large and its median suture extends upon the last three rings. The anterior feet are very large, and cannot be concealed under the anterior portion of the body, as they are in the *Portuni* and *Platyonychi*; their third joint is spiny anteriorly and reaches much beyond the carapace; the hand is in general rough, with a considerable number of teeth, and is at least as long as the carapace. The three succeeding pairs are much shorter, and diminish in length successively; their tarsus is, in general, styliform. The fifth pair are, as ordinarily, the shortest of all, their third joint is nevertheless elongated, and at the extremity of its anterior border there is a rather strong spine, a disposition which never exists in the *Portuni* or the *Platyonychi*, and is extremely rare in the *Lupeæ*; towards their termination these feet become very wide, and their tarsus is oval. The abdomen presents nothing remarkable. (M. E.)

M. Milne Edwards divides the genus into the following sections:—

1.

Fronto-orbital border not occupying more than two-thirds of the width of the carapace, and forming a rather open angle with the latero-anterior borders, which are armed with six or seven teeth.

Hexagonal Thalamitæ.

2.

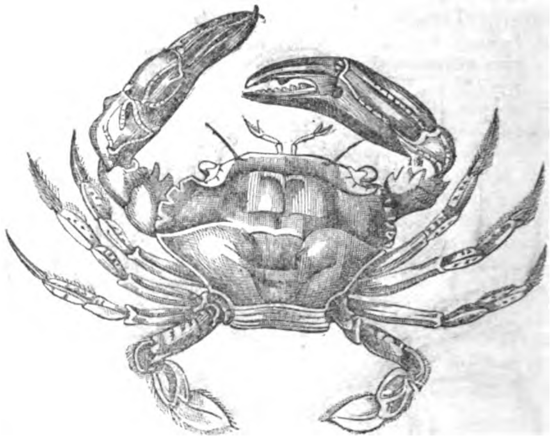
Fronto-orbital border occupying nearly the whole width of the carapace, and forming a nearly right angle with the latero-anterior borders, which are armed with four or five teeth.

Quadrilateral Thalamitæ.

The latter form the first subgenus in M. Milne Edwards's arrangement.

a. Species having the front entire or divided into lobes, but with no teeth.

Example, *Thalamita Chaptalii* (*Portunus Chaptalii*, Aud. *Crust. Sav. Egypte*). Length about an inch. *Locality*—The Red Sea.



Thalamita Chaptalii.

b. Species whose front is armed with deeply cut and flattened teeth.

Example, *Thalamita crenata*. (*Portunus crenatus*, Latr. *Thalamita Admete*, Guerin, *Icon. Cr.*, pl. 1, f. 4.)

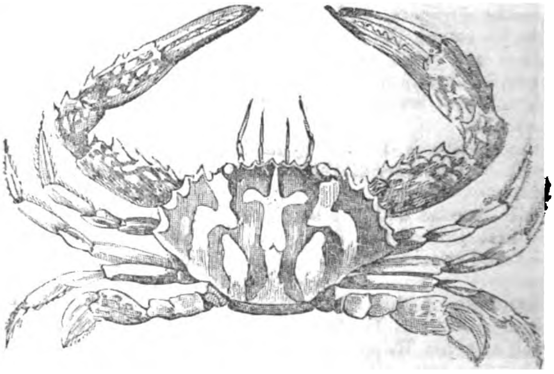
2nd Subgenus. (Hexagonal Thalamitæ.)

a. Species having the latero-anterior border of the carapace armed with six teeth.

a. Last lateral tooth nearly the same size as the preceding.

a*. Anterior feet armed with spines, but without elevated granulations.

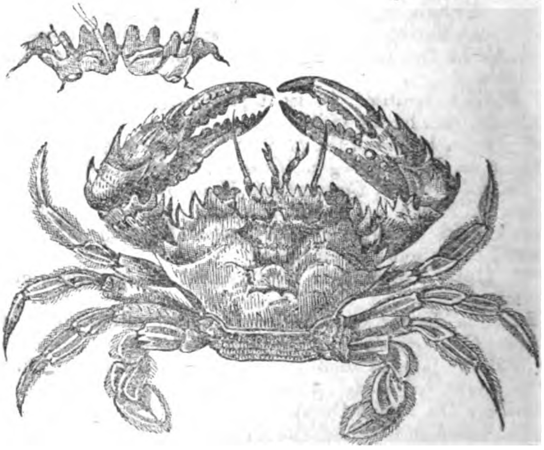
Example, *Thalamita crucifera* (*Portunus cruciferus*, Fabr. and Latr.; *Cancer sexdentatus*, Herbst?). Length from three to four inches; colour reddish with yellow spots and bands, the median markings resembling a cross. *Locality*—The Indian Ocean.



Thalamita Crucifera.

a**. Anterior feet presenting between the spines with which they are armed, a great number of tubercles or elevated granulations.

Example, *Thalamita Natator* (*Cancer Natator*, Herbst; *Portunus sanguinolentus*, Bosc.). *Locality*—Indian Ocean.



Thalamita Natator.

aa. Last lateral tooth stouter and much more projecting than the others.

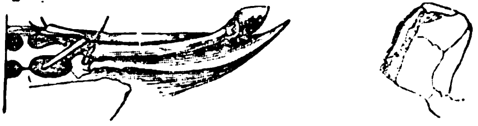
Example, *Thalamita Callianassa* (*Cancer Callianassa*, Herbst). Length about an inch. *Locality*—Indian Ocean.

b. Species having the latero-anterior border of the carapace armed with seven teeth, two of which are rudimentary.

Example, *Thalamita erythrodactyla* (*Portunus erythrodactylus*, Lam.). Length 2½ inches. *Locality*—Australasia.

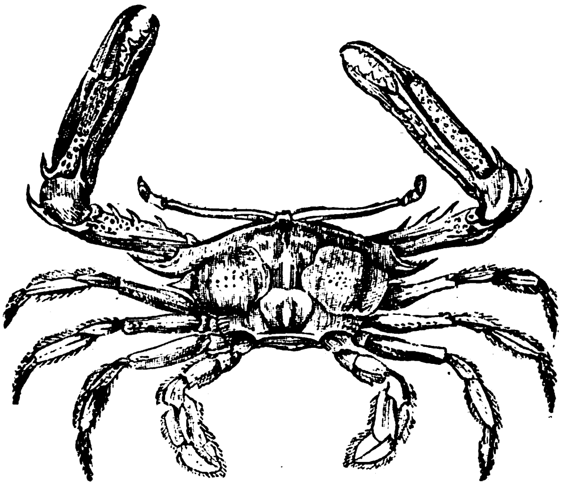
Podophthalmus. (Lam.)

M. Milne Edwards justly observes, that of all the Portunians the *Podophthalmi* have the most remarkable aspect, and characters the most easy to seize. The enormous length of their ocular peduncles, which are very short in the other *Swimming Brachyura*, is sufficient to distinguish them at first sight.



Eye, orbit, jaw-foot, &c. of Podophthalmus.

Generic Character.—Carapace of a very much elongated quadrilateral form, the two lateral sides of which are strongly truncated, and with its antero-posterior diameter not equalling the half of its transversal diameter. Its anterior border, which is nearly straight, is about four times as long as the posterior border. The front, or space comprised between the two eyes, is linear, and on each side the anterior border of the carapace is hollowed throughout its length into a very long and deep gutter, which constitutes the orbits; the external angle of these ocular cavities separates the anterior border of the carapace from its lateral border, the direction of which, very oblique, is the same throughout its length. The eyes are carried on delicate peduncles of extreme length; and these osseous stems are inserted near the median line of the front, and carry at their extremity the second ocular piece, whilst in the *Ocypodians*, where the eyes are also very much developed, it is on the development of this second piece, and not the first, that the length depends. The ocular bulb is not very large, and reaches the lateral extremity of the carapace. The internal antennæ are situated below the origin of the eyes, a disposition which is met with in no other Portunian, and their stem cannot bend itself back into the cavity where they are lodged. The external antennæ are also below the eyes; they are placed between the antennary fossets and the orbits, at the external side of the first, and their basilary joint is soldered with the borders of these two cavities, so as to complete their walls and to separate them from each other; the moveable stem which terminates these antennæ is formed of two small peduncular joints and of a slender and rather short multiarticulate filament. The *buccal frame* is extremely wide, and is only separated from the antennary fossets by a very delicate border; its anterior border is about twice as long as its lateral borders, and these last are directed obliquely backwards and inwards. The external jaw-feet leave a considerable space between them, and their third joint is nearly as wide as it is long; but it is so truncated forwards and inwards, that its form has been compared to a hatchet, the extremity of whose trenchant edge gives insertion to the succeeding joints, which are very large. The first pair of feet are large, and terminate by a nearly straight hand; when they are bent they reach much beyond the borders of the carapace. The succeeding feet are much less than the anterior pair, and the third pair are longer than the others. The joint which terminates the second, third, and fourth pairs is styliform and a little flattened. The fifth pair are very wide and in the form of natatory oars. The abdomen presents nothing remarkable in the females; but in the males it is triangular, and composed of five moveable pieces only. (M. E.)



Podophthalmus vigil.

Example, *Podophthalmus vigil* (*Portunus vigil*, Fabr *Podophthalmus spinosus*, Lam.). The only species known. Length from two to four inches. *Locality*—Indian Ocean.

Fossil Portunians.

M. Milne Edwards remarks that the fossil crustacean figured by Davilla (*Catal.*, t. iii., pl. 3, f. 6), and designated by M. Desmarest under the name of *Portunus leucodon* (*Cr. Foss*, p. 86, pl. 6, f. 1, 3), bears some analogy to *Lupea Tranquebarica*. The *Podophthalmus Defrancii* of the work last quoted appears, M. Milne Edwards observes, to differ principally from *Podophthalmus vigil* by the absence of the sharp spines which terminate the lateral angles of the carapace in the latter; but as the internal cast only is known, he remarks that it is very possible that this negative character does not really exist.

PORTUS, FRANCIS, a celebrated philologer, born in 1511, in the island of Crete. He lost both his parents at an early age, and was sent by a friend to Padua, where for six years he studied classical literature and philosophy. After the death of his friend and benefactor he repaired to Venice, where his talents procured him the directorship of the school for young Greeks. But owing to his inconsiderate expressions on matters of religion, he soon lost his place. He now went to Modena, where in 1536 he was made professor of Greek literature, after having signed some articles of faith, to which at first he strongly objected. He held this office for six years, at the end of which he exchanged Modena for Ferrara, to undertake the education of the sons of the Dutchess Renée of France. In this capacity he also carried on her correspondence with Calvin, whose doctrines this lady had secretly adopted. During his stay at Ferrara, Portus was made a member of the Academy of the Filareti. After the death of her husband, the dutchess returned to France, and Portus, from fear of persecution for his religious opinions, went to Geneva, where he obtained the rights of a citizen and a professorship in the university (1562). Here he spent the remaining years of his life, partly in fulfilling the duties of his office, and partly in writing those works by which he established his reputation as a scholar and a critic. He died on the 5th of June, 1581.

Portus has written explanatory and critical commentaries on various antient authors, such as Aristotle ('Rhetoric'), Aphthonius, Hermogenes, Longinus, Pindar, on the 'Greek Anthology,' some works of Xenophon, on Thucydides, and others. He translated into Latin the treatise of Apollonius of Alexandria, 'De Syntaxi, seu Correctione Orationis,' the 'Psalms,' the hymns and letters of Synesius, and the odes of Gregorius Nazianzenus. His son Aemilius Portus published, in 1584, six dissertations and some other works of his father. It is said that there are still some MSS. of Francis Portus in the library of Este, containing commentaries on several orations of Demosthenes and on Sophocles, which have never been printed.

PORTUS, ÆMILIUS, the son of Francis Portus, was born, about 1550, at Ferrara. In his youth he was instructed by his father in the antient languages and literature. After the death of his father he left Geneva, and in that same year (1581) he was made professor of Greek at Lausanne, where he remained for ten years, devoting his leisure hours to preparing new editions of antient authors. In 1592 he was invited to the chair of Greek literature in the university of Heidelberg, of which he afterwards became one of the greatest ornaments. He died at Heidelberg in 1610, at the age of 60 years.

The numerous works of Aemilius Portus consist of commentaries, translations, and original works. Among the first we may mention his Commentary on Pindar (1598), his edition of Euripides, with notes of Canter, Brodaeus, Stibilinus, and some of his own, Geneva, 1602; Aristophanes, Geneva, 1607; Aristotle's Rhetoric (the translation was made by Aemilius, the Commentary by his father), Spire, 1598; Homer's Iliad, Xenophon, and Thucydides. He translated into Latin the work of Proclus, 'De Theologia Platonis,' published at Hamburg in 1618; the Lexicon of Suidas, Colonia Allobrogum, 1619; a reprint appeared at Geneva in 1630. He also translated Thucydides and the 'Roman Antiquites' of Dionysius of Halicarnassus. The following are the original works of Aemilius Portus: 'Oratio de variarum Linguarum usu, necessitate, præstantiâque,' Cassel, 1611, 4to.; 'Dictionarium Ionicum Graeco-Latinum, quod indicem in omnes Herodoti libros continet,' Frankfort, 1603, 8vo.; a reprint of it appeared at Oxford in 1809. 'Dictionarium Doricum Graeco-Latinum, quod Theocriti, Moschi, Bionis, et Simmiae variorum opusculorum interpretationem continet,' Frankfort, 1604; 'Pindaricum Lexicon, in quo non solum Dorismi Pindaro peculiares, sed etiam verba phrasesque non vulgares et in aliis lexicis omissæ declarantur,' Hanau, 1604; 'De prisca Græcorum Compotatione,' Heidelberg, 1604; 'De Nihili Antiquitate et multiplici Potestate,' Cassel, 1609.

PORUS (Πῶρος), the name given by Greek writers to several Indian kings. From its frequent occurrence, it appears to have been the name of a family or tribe, rather than the proper name of an individual. Some modern writers suppose it to be the same word as the Sanskrit *paura*, a 'citizen;' but Lassen (*Pentapotamia Indica*, p. 17, 18) with more probability connects it with *Paurava*, or descendants of *Puru*, which we know, from the ancient writings of the Hindus, to have been the name of several Indian dynasties.

Alexander, in his invasion of India, met with two different kings of this name, one of whom ruled over the country between the Hydaspes and Acesines, and the other over the country betweeen the Acesines and Hydraotes (Ravee). The former made a formidable resistance to Alexander, but was conquered. Alexander however treated him with respect, and restored to him his kingdom, with enlarged limits. [ALEXANDER, p. 300.] The other Porus did not wait the arrival of Alexander, but fled to the kingdom of the Prasii. His dominions were given to the Porus whom Alexander conquered. (Arrian, *Anab.*, v. 20, 21, 29.) Porus however did not long survive Alexander. He was treacherously killed by Eudamus, B.C. 317. (Diod. Sic., xix. 14.)

Strabo mentions (xv., p. 686) that an Indian king of the name of Porus sent an embassy to Augustus.

POSEIDON. [NEPTUNUS.]

POSEN, a province of the Prussian monarchy, was formerly a part of the kingdom of Poland. On the first partition of Poland in 1772, the part of Posen to the north of the Netze, and on the second partition in 1793, the remaining part fell to the share of Prussia: this, together with the part of the kingdom south of the Vistula, as far as Warsaw, acquired by Prussia on the third partition, received the name of South Prussia. In 1807 all South Prussia was taken from Prussia to form part of the duchy of Warsaw. In 1815 the congress of Vienna restored the original province of Posen to Prussia by the name of the grand-duchy of Posen. It lies between 51° 10′ and 53° 32′ N. lat., and between 15° 7′ and 18° 38′ E. long. It is bounded on the north by the province of Prussia, on the east by the kingdom of Poland, on the south by Silesia, and on the west by Brandenburg. The area is 12,250 square miles, divided into the two governments of Bromberg and Posen.

Face of the Country, Soil, Climate, &c.—This province is perfectly level, except the banks of the Wartha in the circle of Obernik, which are rather more elevated, and there is here and there a hill on the frontiers of Silesia. The soil is partly marsh, which is very fertile, and partly sandy, but even here the sand is so mixed with more solid elements, especially loam, that the soil may be considered as tolerably good. The most fertile parts are the country on both sides of the Wartha, and the Netzbruch, a low tract on the river Netze, about 90 miles in length, and not above 3 in breadth, which, having been completely secured by dikes by Frederick II., is now converted into fine corn-land and meadows, with farmhouses and villages, where, under the Polish government, there were only unprofitable bogs and thickets. The river Wartha, which traverses the province in its whole breadth, and the Netze, are navigable. The Netze is connected by the Bromberg canal with the Brahe, which has been made navigable, and falls into the Vistula, which only touches the frontier for a short distance above Thorn, but is of great advantage by opening a communication with the Baltic. Besides these there are several other rivers, so that the province is very well watered. The Bromberg canal, which is twenty miles long, was constructed under Frederick II., at the expense of 200,000 dollars. There are several lakes, the largest of which is the Gopplo lake. The air is pure and healthy.

Natural Productions.—The chief productions are corn of all kinds, pulse, culinary vegetables, flax, and some hemp; tobacco, hops, fruit, and timber; the common domestic animals, game, poultry (especially geese), fish, and bees. There are limestone, freestone, saltpetre, and bog-iron, of which no use is made. Agricultural operations are carried on in a very careless manner. The country suffered very severely by the late wars, and this, with the changes in the government, checked the agricultural improvements, which had been successfully commenced under the Prussian government. Since 1815 however a better state of things has been gradually established. 'The common people,' says Dieterici, 'live in a very simple and poor manner; but it is undeniable that, especially of late, a considerable improvement has taken place in their condition. Great public buildings, one of which is the citadel of Posen, the organization of the public schools, and the regulation of the relations of the landowners and the peasants, ameliorate the condition of the common people.'

Trade and Manufactures.—The exports consist chiefly of corn, especially wheat, a large quantity of wool, timber, cattle, tallow, hides, wax, honey, hogs' bristles, and feathers. Manufactures were first introduced by German settlers, who fled from Silesia in consequence of religious persecution, and founded several towns on the frontier, such as Rawitsch, Fraustadt, Bojanows, Lissa, Kosche, and Meseritz. These towns and several others manufacture cloths of such good quality, that the Jews often sell them for Silesian and Dutch. Formerly considerable quantities of these cloths went to Russia; but the rigorous prohibitory system adopted by Russia has nearly put a stop to all trade between the two states.

Population.—The population amounted, in 1837, to 1,169,706 inhabitants, of whom the great majority are Roman Catholics, 250,000 Protestants, and 70,000 Jews. The Roman Catholics are under the archbishop of Gnesen and Posen. Though much has been done of late years, education is still very backward in this province. The great mass of the population are Poles, and Polish is the general language; there are however many strangers, especially Germans, who inhabit almost all the towns on the frontiers of Silesia and Brandenburg, and whose numbers were stated, twenty years ago, by Hassel, at 140,000.

The principal towns besides the capitals [BROMBERG; POSEN] of the two governments are:—1. In the government of Bromberg, Gnesen, an old ill-built town, with 6000 inhabitants, of whom 1800 are Jews; it is the see of a Roman Catholic archbishop, formerly the primate of Poland. Besides the cathedral, there are seven other Roman Catholic churches, two monks' convents, one nuns' convent, and a seminary for Roman Catholic clergy. The inhabitants manufacture some woollen cloth and linen, and there are breweries and distilleries. Inowratzlaff, an ill-built town, on a fertile plain, has 5100 inhabitants, of whom 2000 are Jews, who have considerable distilleries of brandy, breweries, and saltpetre works. There are five Roman Catholic churches, a Franciscan convent, and a synagogue. Schönlanke, a well-built town, with 4000 inhabitants, who have a considerable manufacture of woollen cloths. 2. In the government of Posen, Lissa, or Polish Lissa, has 8667 inhabitants, of whom 3470 are Jews. This is one of the chief manufacturing towns of this country, and belongs to Prince Sukowsky: it has a palace, a handsome market-place, a gymnasium, four Roman Catholic churches and one Lutheran church, a large synagogue, and extensive manufactories of woollen cloth, linen, snuff, succory (as a substitute for coffee), and carriages. The trade is very flourishing. Rawitsch, situated in a marshy spot near the frontiers of Silesia, has 8316 inhabitants (1786 Jews), who are mostly Germans. It is pretty well and regularly built, has a gymnasium, a fine Lutheran church, a handsome town-hall, and manufactures of woollen cloth, linen, leather, tobacco, and earthenware. Meseritz, situated in a beautiful and fertile country on the river Obra, has 4500 inhabitants, chiefly Germans, of whom 1150 are Jews. The manufacture of woollen cloth is very considerable. Krotoschin has 6337 inhabitants, of whom 2213 are Jews. They have manufactures of woollen cloths, linen, tobacco, and succory. There are also tanneries, dyeing-houses, and distilleries. This town has both a Lutheran and a Roman Catholic church, and a synagogue, with Lutheran, Roman Catholic, and Jewish schools. Fraustadt, situated on the frontiers of Silesia, consists of the old and new town, and has one Lutheran and three Roman Catholic churches, a Roman Catholic gymnasium, a Lutheran school, a convent of Bernhardine monks, an orphan asylum, and other public institutions. The inhabitants are 6257 (mostly Germans), of whom 565 are Jews: they have woollen and linen manufactures, breweries, and distilleries, and carry on a considerable trade in corn, cattle, wool, &c. Kempen, on the Silesian frontier, has 6154 inhabitants, of whom 3474 are Jews, who carry on a considerable trade in horses and goods with Silesia. They have manufactures of cloth, linen, tobacco, and soap.

POSEN. This government is situated between 51° 10′ and 52° 50′ N. lat., and between 15° 7′ and 18° 23′ E. long. It is bounded on the north by Bromberg, on the east by Poland, on the south by Silesia, and on the west by Brandenburg. It is considerably the larger of the two divisions of the province, the area being about 7000 square miles, and the number of inhabitants 788,578 in 1837. This, according to the official returns, is 2451 to a German square mile; whereas that of the whole province was only 2180, and that of the government of Bromberg only 1774 to a German square mile. It is divided into seventeen circles.

POSEN (in Polish, *Posnan*), the capital of the province and of the government of the same name, is situated in 52° 24′ N. lat. and 17° E. long., in a sandy tract on the left bank of the Wartha, where it is joined by the Loyna. It has three suburbs, four gates, and is pretty regularly built. The chief public buildings are—the castle, situated on an eminence; twenty-four Roman Catholic churches, the most remarkable of which are the cathedral and the church of St. Stanislaus, the latter being a masterpiece of Italian architecture; two Protestant churches, a Greek chapel, a synagogue, five convents, one of which is that of the Grey Sisters, who devote themselves to attendance on the sick; the episcopal palace, the theatre, the chief guard-house, the town-hall, &c. There are many useful public institutions, such as a gymnasium, a seminary for priests, another for schoolmasters, a school for midwifery, and numerous schools for children of both sexes, two hospitals, and a poorhouse. Posen is the residence of the archbishop of Posen and Gnesen, of the governor of the province, of the chief president, and is the seat of all the government offices of the province. The inhabitants amount to 32,456 (of whom 6828 are Jews), exclusive of the garrison. They have some manufactures of chintzes, calico, tobacco, leather, woollen cloth, ticking, sealing-wax, and carriages. There are likewise breweries distilleries, several printing-offices and lithographic presses. The city has some trade; the three annual fairs are well frequented, especially that at Midsummer, when all the landholders of the surrounding country attend. It is intended to make Posen a fortress of the first rank. The works were commenced ten years ago, and will probably not be finished for ten years more. Ten millions of dollars have already been expended on them.

Posen is one of the oldest cities in Poland: on the first introduction of Christianity, in the tenth century, it was erected into a bishopric by the emperor Otho I., and became in the thirteenth century the residence of the dukes of Poland. It was a member of the Hanseatic league, and many German, English, and Scotch merchants settled in it, from whom several still existing families claim to be descended.

(Dieterici, *Uebersicht des Verkehrs im Preussischen Staate*, &c., 1838; Hörschelman; Cannabich; Stein; Müller, *Geograph. Wörterbuch des Preussischen Staates*, 1836; Heidemann, *Topographisch-Statistisches Wörterbuch der Preussischen Monarchie*, 1836; Schlieben, *Gemälde der Preussischen Monarchie*, 1830; Official Population Returns for 1837.)

POSIDONIA. [PÆSTUM.]

POSIDO'NIA (Ποσειδῶν, 'Neptune'), a marine genus of fossil conchifera, belonging to the Monomyaria of Lamarck. Goldfuss figures several fossil species from the series of Westphalian rocks lately referred by Mr. Murchison to the carboniforous system, from the Keuper (upper part of the red-sandstone series), and the Lias. The best known foreign species is Posidonia Becheri; a British species very like it occurs in the black-limestone of the culm deposits of central Devon. Much importance is justly attached to the occurrence of these fossils. We have not seen specimens exactly like those from Devonshire in any other part of Britain.

POSIDO'NIUS (Ποσειδώνιος), a Greek philosopher, was a native of Apameia in Syria, but a citizen of Rhodes, where he resided the greater part of his life. (Strabo, xiv., p. 655; Athen., vi., p. 252. e.) The dates of his birth and death are unknown; but he must have been born during the latter half of the second century before the Christian æra, as he was a disciple of Panætius, who probably died about B.C. 100, and whom he succeeded as the head of the Stoic school. He removed to Rome in the consulship of Marcus Marcellus (Suidas, *Posidon.*), B.C. 51, and probably died soon after. He lived, according to Lucian (*Macrob.*, c. 20), to the age of eighty-four.

Posidonius was one of the most celebrated philosophers of his day. Cicero, who had received instruction from him (Cic., *De Fato*, c. 3; *De Nat. Deor.*, i. 3; *De Fin.*, i. 2), frequently speaks of him in the highest terms. Pompey also appears to have had a very high opinion of him, as we read of his visiting him at Rhodes shortly before the war against the pirates, B.C. 67 (Strabo, xi., p. 492), and again in B.C. 62, after the termination of the Mithridatic war. (Plut., *Pomp.*, c. 42; Plin., *Hist. Nat.*, vii. 30)

Posidonius appears to have been a man of very extensive information. Besides his philosophical treatises, he wrote works on geography, history, and astronomy; but none of them have come down to us, with the exception of their titles, and a few sentences quoted by Cicero, Diogenes Laertius, Strabo, and others. He seems to have travelled in different parts of the world for the purpose of collecting information. We learn incidentally from Strabo (xiii., p. 614; iii., p. 165; iv., p. 197), that he had been in Spain, Liguria, and Gaul. Plutarch was also indebted to Posidonius, among others, for the materials of several of his lives. This is the case in the Lives of Marcellus, Paulus Æmilius, the Gracchi, and others; but particularly in the Life of Marius, with whom Posidonius had been personally acquainted. (Plut., *Marius*, c. 45.) Posidonius wrote 'Meteorologica.' Cicero mentions (*Nat. Deor.*, ii. 34) his artificial sphere, which represented the motions of the heavens.

Posidonius was a much stricter Stoic than his master Panætius. [PANÆTIUS.] He maintained that pain was not an evil, as we learn from an anecdote which Pompey frequently related respecting his visit to the philosopher at Rhodes. (Cic., *Tusc. Disp.*, ii. 25.) His works on Divination and the Nature of the Gods are referred to by Cicero, who probably made use of them in his works on the same subject. (Cic., *De Div.*, i. 3, 30, 64; *De Nat. Deor.*, i. 44.)

Strabo says (xi. 492) that Posidonius wrote an account of the wars of Pompey, but did not pay much attention to accuracy. This account was however probably contained in his historical work, of which Athenæus quotes (iv., p. 168. d) the 49th book. (Compare Athen., iv., p. 151. e.) For further information respecting the opinions and writings of Posidonius, see 'Posidonii Reliquiæ Doctrinæ. Collegit atque illustravit Janus Bake. Accedit D. Wyttenbachii Annotatio. Lugduni Bat.' 1810, 8vo.

There was another Posidonius of Alexandria, who was a pupil of Zeno, and consequently was prior to Polybius. Suidas however, by mistake, ascribes to this Posidonius a continuation of Polybius, in fifty-two books, which is evidently the work of the younger Posidonius.

POSI'LIPO, the name of a long hill which forms the boundary of the town and immediate territory of Naples towards the west, and divides it from the district of Pozzuoli. The hill consists of tufo, easily cut and excavated. It is connected on the north with the hill of Sant' Elmo, which commands Naples on the north-west. The hill of Posilipo runs in a south-south-west direction close to the sea-shore for about three miles, terminating in a bold jutting cape facing the small island of Nisita. The side of the hill towards Naples is covered with country-houses and gardens, which enjoy a delightful prospect of the city and bay, and along the base of the hill runs a fine new carriage-road leading to Pozzuoli. The old road from Naples to Pozzuoli passes through a tunnel three-quarters of a mile in length, which perforates the hill in the direction of its breadth, and is called Grotta di Posilipo, and also Grotta di Pozzuoli. This tunnel appears to have been made in the time of the Romans, but it was enlarged by the Spanish viceroys of Naples. It is described by Strabo (p. 246. Casaub.) as wide enough to allow two carriages to pass, and as lighted by holes cut through the mountain from the top: he gives no name to the tunnel. Pliny (ix. 53) mentions Pausilypum as the name of a villa near Naples.

POSITIVE. [Negative.]

POSSE COMITATUS (literally, the power of a county) comprises all able-bodied males within the county between the ages of 15 and 70 years. All such persons, without any exception, are bound to aid the sheriff in all matters that relate to his office; and he is fineable if he neglect to avail himself of their aid. In case of any invasion, rebellion, riot, &c., or breach of the peace within the county, all such persons, on pain of fine or imprisonment, are bound to attend him on being charged by him to do so, and to assist in opposing and suppressing them. They may come armed, and are justified in killing a person in case of resistance. The power of the county may also be raised when necessary for the purpose of apprehending traitors, felons, &c., and that even within particular franchises. It is lawful for any peace-officer, and perhaps even for a private person, to raise a competent number of people for the purpose of opposing and suppressing enemies, rebels, rioters, &c. within the county. But all such persons are punishable if they use unnecessary violence or create false alarms. It is also the duty of the sheriff or any minister of the king having the execution of the king's writs, or process even in a civil nature, who meets with actual resistance in his attempt to execute them, to raise a power sufficient to quell the resistance. (2 Inst., 193, 194; 3 Inst., 161; 1 Hawk., P. C., 152, 156.)

POSSESSION. In endeavouring to explain the legal meaning of this term, we shall commence with the following extracts from Savigny's work on the Right of Possession (*Das Recht des Besitzes*, Giessen, 1827).

'All the definitions of possession are founded on one common notion. By the notion of possession of a thing we understand that condition by virtue of which not only are we ourselves physically capable of operating upon it, but every other person is incapable. This condition, which is called detention, and which lies at the foundation of every notion of possession, is no juristical notion, but it has an immediate relation to a juristical notion, by virtue of which it becomes a subject of legislation. As owership is the legal capacity to operate on a thing at our pleasure, and to exclude all other persons from using it; so is detention the exercise of ownership, and it is the natural state which corresponds to ownership as a legal state. If this juristical relation of possession were the only one, everything concerning it that could juristically be determined, would be comprehended in the following positions:—the owner has the right to possess; the same right belongs to him to whom the owner gives the possession; no other person has this right.

'But the Roman law, in the case of possession, as well as of property, determines the mode in which it is acquired and lost; consequently it treats possession not only as a consequence of a right, but as a condition of rights. Accordingly, in a juristical theory of possession, it is only the rights of possession (jus possessionis) that we have to consider, and not the right to possess (called by modern jurists jus possidendi), which belongs to the theory of property.

'We now pass from the notion of mere detention to that of juristical possession, which is the subject of this treatise. The object of the first part, which is the foundation of the whole investigation, is to determine this notion formally and materially. Formally, by explaining those rights which presuppose possession as a condition, and consequently determining the signification which the non-juristical notion of detention obtains in jurisprudence, in order to its being considered as something juristical, that is, Possession; materially, by enumerating the conditions which the Roman law requires for the existence of possession, and consequently the positive modifications under which detention can be viewed as possession.

'The formal determination of the notion by force of which alone possession can become a subject of jurisprudence, is divided into three parts; first we must determine the place which possession, as a legal relation, occupies in the system of Roman law. We must then enumerate the rights which the Roman law recognises as a consequenceo f possession, and we must also examine the rights which are improperly considered rights of possession. It will then be easy to answer the questions whether possession is to be considered as a right, and whether as a jus in re. The first and simplest mode in which possession appears in a system of jurisprudence consists in the owner having the right to possess; but we are here considering possession independent of ownership, and as the source of peculiar rights; the former of these two questions therefore may be expressed thus—in what sense has possession been distinguished from ownership? a mode of expression which has been used by many writers.

'In the second place we must determine how the different senses in which possession occurs in the Roman law are distinguished from one another by the mode of expression; and particularly what were the significations of possessio generally, and possessio naturalis, and possessio civilis, among the Roman jurists.

'In the whole system of Roman law there are only two consequences which can be ascribed to possession of itself, as distinct from all ownership, and these are usucapion and interdicts.

'The foundation of usucapion is the rule of the Twelve Tables, that he who possesses a thing one or two years becomes the owner. In this case bare possession, independent of all right, is the foundation of property, which possession must indeed have originated in a particular way, in order to have such effect; but still it is a bare fact, without any other right than what such effect gives to it. Accordingly it is possession itself, distinct from every other legal relation, on which usucapion, and consequently the acquisition of ownership, depends.

'Possessorial interdicts are the second effect of possession, and their relation to possession is this: possession of itself being no legal relation, the disturbance of possession is no violation of a legal right, and it can only become so by the circumstance of its being at the same time a violation of a legal right. But if the disturbance of possession is effected by force, such force is a violation of right, since every forcible act is illegal, and such illegal act is the very thing which it is the object of an interdict to remedy. All possessorial interdicts then agree in this: they presuppose an act which in its form is illegal.*

'Now since possessorial interdicts are founded on such acts as in their form are illegal, it is clear why possession, independent of all regard to its own rightfulness, may be the foundation of rights. When the owner claims a thing as his property (vindicatio), it is a matter of perfect indifference in what way the other party has obtained possession of it, since the owner has the right to exclude every other person from the possession of it. The case is the same with respect to the interdict, by which the 'missio in possessionem' is protected: this interdict is not a possessorial interdict, for the 'missio' itself gives no possession, but it gives a right to detention, and this right is made effective in the same way as in the case of property. On the other hand, he who has the bare possession of a thing has not on that account any right to the detention, but he has a right to require from all the world that no force shall be used against him. If however force is used and directed against the possession, the possessor protects himself by means of the interdicts. Possession is the condition of these interdicts, and in this case, as in the case of usucapion, it is the condition of rights generally.

'Most writers take quite a different view of the matter, and consider every violation of possession as a violation of a legal right, and possession consequently as a right of itself, namely, presumptive ownership, and possessorial plaints as provisional vindications. This last, which is the practical part of this opinion, is completely confuted in a subsequent part of this treatise; but it is proper to show here how far such a view is true, as this may be a means of reconciling conflicting opinions. The formal act of illegality above mentioned is not to be so understood, as if possessorial interdicts were a necessary consequence of the independent juristical character of force, and obviously sprung out of it. This consequence of force, namely, that possession of the thing must be restored to the person who has been ejected, without regard to the question whether or not he has any right to the thing, is rather simply a positive rule of law. Now if we ask for the reason of this kind of protection being given against force, that is, why the ejected party should recover the possession to which he may possibly have no title, it may be replied, that the reason is the general presumption that the possessor may be the owner. So far then we may view possession as a shadow of ownership, as a presumed ownership; but this view of the matter only extends to the establishment of the rule of law in general, and not to the legal reason for any particular case of possession. This legal reason is founded rather in the protection against the formal injury, and accordingly possessorial interdicts have a completely obligatory character, and can never be viewed as provisional vindications.'

---

* Possessorial interdicts were not limited to cases of violence; they comprehended the three *vitia possessionis*. (Terence, *Eunuch.*, ii. 3; v. 27.)

The special object of Savigny's essay may be collected from these passages. The legal principles here developed are applicable to every system of jurisprudence. There must always be a distinction between the right to possess, which is a legal consequence of ownership, and the right of possession, which is independent of all ownership. The owner of a thing may not have the possession, but he has a right to the possession, which he must prosecute by legal means. The possessor of a thing, simply as such, has rights which are the consequences of his possession; that is, he is legally entitled to be protected against forcible ejection or fraudulent deprivation; his title to a continuance of his possession is good against all persons who cannot establish their right to the thing, and this continued possession may, according to the rules of positive law in each country, become the foundation of ownership. It may be that the acquisition of possession may also be the acquisition of ownership, or that the acquisition of possession may be essential to the acquisition of ownership. Thus, in the case of occupation, the taking possession of that which has no owner, or the acquisition of the possession, is the acquisition of the ownership. Also, when a thing is delivered by the owner to another, to have as his own, the acquisition of the possession is the acquisition of the ownership. In these examples, ownership and possession are acquired at the same time, and there is no right that belongs to the possessor as possessor; his rights are those of owner. But the form and mode of the acquisition of the possession, viewed by itself as distinct from the acquisition of the ownership, will also be applicable to the cases of possession when possession only is acquired. For possession of itself is a bare fact, though it has legal consequences; and being a bare fact, its existence is independent of all rules of the civil law or of the jus gentium, as to the acquisition and loss of rights. (Savigny, p. 25.)

Having shown that in the Roman law all juristical possession has reference to usucapion and interdicts, and that the foundation of both is a common notion of juristical possession, Savigny proceeds to determine the material conditions of this notion.

In order to lay the foundation of possession as such, there must be detention, and there must also be the intention to possess, or the 'animus possidendi.' Consequently the 'animus possidendi' consists in the intention of exercising ownership. But this ownership may either be a person's own ownership or that of another: if the latter, there is no such 'animus possidendi' as makes detention amount to possession. In the former case a man is a possessor, because he treats the thing as his own: it is not necessary that he should believe it to be his own.

Whether then we are considering possession as such, or that possession which is concurrently acquired with ownership, or which complete the acquisition of, or is the exercise of, ownership, the material facts of possession are the same. When ownership is transferred from one man to another, every system of law must require some evidence of it. But the evidence of the transfer of ownership may be entirely independent of the evidence of acquisition of possession; and also the evidence of the acquisition of possession may be inseparable from that of the acquisition of ownership. There must then generally be some act which shall be evidence of the acquisition of possession, whether possession as such is obtained without ownership, or possession accompanied by ownership, or possession as necessary to the complete acquisition of ownership, or possession as simply the exercise of ownership.

Bracton, the oldest law writer from whom we obtain any comprehensive notion of our whole system, has framed his notions of possession on and borrowed his definitions from the Roman law. Whether he has always rightly understood them is a matter that would require a very careful investigation.

Bracton (c. 17) uses possessio and seisina as synonymous. He observes that it is not sufficient for one man's right to be transferred to another, unless that other obtain 'seisina;' and he adds, 'possessio sive seisina multiplex est.' He defines possessio to be 'corporalis rei detentio i., corporis et animi cum juris adminiculo concurrente.' He therefore limits it to corporeal things, for incorporeal things are incapable of tradition or delivery, but may be said 'quasi possideri;' and he requires both the corporeal act and the animus, together with right, in order to give possessio, which, thus understood, is complete ownership. Accordingly verus possessor is owner. (Fleta, iii., c. 3, s. 1.) He divides possessio into 'civilis, quæ animo tantum tenetur,' that is, in which there is an intention to hold; and 'naturalis, quæ corpore;' and this latter may be just, that is, with good title; or unjust, that is, without good title. To acquire complete possession, it must be acquired 'animo et corpore:' there must be both the mental affection (*possidendi affectus*, as Bracton elsewhere calls it, fol. 40) and the corporeal act; possession can only be completely lost 'animo et corpore,' for it may be lost 'corpore,' and retained 'animo.' Among various kinds of possession he enumerates nuda, where a person has no right to the thing; and vestita, where he has 'jus, titulus, tempus.' As an instance of a case, where there is 'nihil juris in re, sed aliquid possessionis,' he mentions the case of a man being seised or possessed by intrusion. As another kind of possession, but which is manifestly distinguishable from the others, he mentions the possession of a custos, creditor, or any person of the kind. These examples will be sufficient to show that the senses of possessio at that time were very various. The essential part of all of them is detentio.

In the transfers of freeholds, mentioned by Bracton, traditio or livery is defined to be 'in possessionem inductio de re corporali;' as soon as this traditio is made by the owner, the person to whom it is made has 'liberum tenementum,' a freehold estate (Bracton, fol. 39), 'propter conjunctionem juris et seisinae et mutuum utriusque partis consensum.'

A person who held land for a term of years (firmarius) had no 'liberum tenementum' (fol. 27), but he was certainly said 'possidere,' but there was not the 'conjunctio juris et seisinae,' that is, a possessio which made a liberum tenementum. Again (c. 15), when Bracton is treating of one cause or title of possession being turned into another, he says that he who has the usus fructus and the terminus, or term of years, may, during its continuance, and while he is thus in possession, acquire 'liberum tenementum,' if the proper formalities are observed, 'so that there shall not be wanting proof of the new acquisition.' It appears that the owner (dominus) was not said to possess during the continuance of the term; for it is said (fol. 32) 'that the donor and true owner, with the consent of the tenant (tenens), might change one title of possession into another without any change of the possession; nor is it necessary to resume the thing that has been once given and possessed, in order that it may be possessed by a new title.'

It remains to attempt to show some of the many senses in which possession has been or is still used in English law. There seems to have been always a fundamental distinction as to the use and meaning of this word, between land and moveable chattels, of which something more will presently be said. Some of our old writers make the following division of possession as applied to land: 'Possession is actual and in law: *actual* possession is when a man actually enters lands and tenements to him descended; possession *in law* is when lands and tenements descend to a man, and he hath not yet actually entered into them.' (Staundf., *Pl. Cor.*, fol. 198; Cowel.) Now, this actual possession, that is, possessio according to Bracton's definition, is the only possession included in this definition, that is, properly so called. The possession in law is merely the owner's right to possess. This possession in law, that is, ownership and the right to possess, is not full ownership, for if the right to possess is not exercised, that is, does not become an actual possession, it will be lost in course of time. (3 & 4 Wm. IV., c. 27.) It becomes an actual possession by entry, that is, by the owner entering on the land or exercising ownership over it. What shall be sufficient to constitute entry so as to give the owner all the advantages of actual possession, may sometimes be difficult to determine; but actual entry is not always necessary for that purpose. The receipt of the rent from a lessee for years, who has the actual possession of the land, gives to the owner all the legal advantages which are derived from his actual entry.

A lessee for years, who pays a rent, has the actual possession of the premises, and if the landlord enters the premises, except when rent is in arrear, or by virtue of the covenants in the lease, he is a trespasser. Still the owner who receives the rents is often said, in a sense, to be in possession, though he may never have had actual possession. This sense of possession is that which is expressed in the recent Statute of Limitations by the words 'receipt of the profits.' It might be called 'legal possession,' as it is for many purposes a possession which gives all the advantages of actual possession. But since 'legal possession' has been used in a different sense, as will be shown hereafter, the expression cannot conveniently be applied in the case here considered. Nor can we use the phrase 'possession in law;' for that, as above defined, is the owner's right to possess, that is, his present right to actual possession, which in the case here supposed, the owner has not. There appears then to be no one term, except possession simply, that can be used to express that kind of possession of land which a man has who has merely received rent from a lessee.

The old form of conveying a present freehold interest in land was by feoffment, that is, by livery of seisin, or actual delivery of the possession upon the land by the owner, in the presence of witnesses, to the donee or purchaser. Without this ceremony no ownership was transferred. Formerly no writing was necessary in the case of a feoffment. A written instrument is now required (29 Chas. II., c. 3), but the ownership is not transferred without livery of seisin; that is, though one party has agreed to sell and the other to buy, actual possession must be taken by the purchaser in the form required by law. If a lease for years is made to a man at common law, though he thereby acquires an immediate interest in the land (interesse termini), he has no estate till he enters: actual possession is necessary to give him this. The Statute of Uses made a considerable change by enabling a man to acquire an estate in land without actual entry; but the statute does not give him all the advantages of actual entry, or of that which is legally equivalent to actual entry. This leads us to another meaning of the word possession, which is that of vested estate. (Preston, *Conveyancing*, ii. 389.) The words of a bargain and sale under the Statute of Uses, are, 'to the intent and purpose that by virtue of these presents and of the statute for transferring uses into *possession*, the said A. B. may be in the *actual possession* of the premises, and be thereby enabled to take and accept a grant and release of the freehold, reversion, and inheritance,' &c. Possession here means an estate such as under the old law a lessee obtains upon entry; and it may be one which entitles the bargainee to an immediate possession; but it may also be an estate which does not entitle him to immediate possession. There can therefore be no actual possession in the sense in which that word is properly understood and legally defined. If the bargainee is entitled to the immediate possession, but has not entered, he cannot maintain an action of trespass; for in such action he must declare that he is possessed, which means actually possessed. The actual possession of land in right of a freehold estate is called seisin, a word which therefore imports both actual possession and right. Thus, 'things are said to lie in livery when the person in whom the first estate of freehold is vested, has the possession of land in right of this estate.' (Preston, *Estates*, i. 13.)

Possession, when coupled with the word estate, means a present right to possess. 'An estate in possession gives a present right of present enjoyment;' 'an estate in reversion gives a present right of future enjoyment.' (Preston, *Estates*, i. 89.) In this sense of possession, an estate in possession is opposed to an estate in remainder or reversion; but it does not imply actual possession. In the third section of the Act for the Limitations of Actions and Suits (3 & 4 Wm. IV., c. 27), an 'estate or interest in possession' is opposed to an 'estate or interest in reversion or remainder,' and the actual possession of land is referred to in the same section by the terms 'possession or receipt of the profits of the land.' [Statute of Limitations.]

A man is said to be *seised* of a freehold estate; but he is said to be *possessed* of a chattel real. The Statute of Uses does not apply to chattels real.

It remains to speak of a distinction in the word possession as applied to a real estate and a chattel personal. Both may be possessed, but the legal conclusion from the bare fact of possession is different in the case of a real estate and of a personal chattel. 'There is a marked difference between a real estate and a personal chattel: the latter is held by possession; a real estate, by title. Possession of an estate is not even *primâ facie* title. It may be by lease only or from year to year.' (Lord Eldon, Hiern *v.* Mill, 13 Ve., 114.) This seems to mean that, in the case of a chattel, possession is a presumption of ownership; but that possession of land is not; at least not a presumption of a freehold interest. Still it is so far a presumption of some interest, that if a man buys an estate from the owner, knowing that another man is in possession of it, he has notice of whatever interest the person in possession may have in the land; and therefore if the person in possession has a prior contract with the owner for purchasing the land, the second purchaser buys subject to the interest of the person in possession. (Daniels *v.* Davison, 16 Ve., 249; 17 Ve., 433.)

It has been already stated that *actual* possession of land, or what is legally considered actual possession, is necessary in order to give the owner all the advantages of ownership. In the case of chattels personal, ownership is frequently acquired without or rather before actual possession, and it may always be so acquired by contract when the thing agreed to be bought and sold is clearly determined. Sometimes the ownership can only be acquired together with the possession, because the thing only becomes determined by the act of delivery or taking possession. In all cases however when personal chattels are bought and sold, it is often a matter of great nicety to determine whether there has been possession by the purchaser, either as the condition or means of establishing his ownership, or for the purpose of ascertaining from what time a thing has ceased to be in one person's possession and come into the possession of another.

Questions as to this matter often arise in cases of loss, of insolvency of a vendee, &c., when the chattel is transferred from the vendor to the vendee by being *sent*, in which case it is of necessity during a certain time on its journey, or as our law expresses it, *in transitu*. The solution of questions of this kind, which often occur in a commercial country, is sometimes difficult, though many general principles are deducible from judicial decisions. The right of the vendor to stop the thing after it has commenced its journey, continues till the time at which the vendee is legally considered to have acquired possession. [Stoppage in Transitu.]

It is remarked by Savigny (*Das Recht des Besitzes*, p. 185), 'that in the whole theory of possession nothing seems easier to determine than the character of corporeal apprehension which is necessary to the acquisition of possession. By this fact all writers have understood an immediate touching of the corporeal thing, and have accordingly assumed that there are only two modes of apprehension: laying hold of a moveable thing with the hand; and entering with the foot on a piece of land. But as many cases occur in the Roman law in which possession is acquired by a corporeal act, without such immediate contact, these cases have been viewed as symbolical acts, which, through the medium of a juristical fiction, become the substitute for real apprehension.' After showing that this is not the way in which the acquisition of possession is understood in the Roman law, and that there is no symbolical apprehension, but that the acquisition of possession may in all cases be referred to the same corporeal act, he determines what it is, in the following manner:

'A man who holds a piece of gold in his hand is doubtless the possessor of it; and from this and other similar cases has been abstracted the notion of a *corporeal contact generally* as the essential thing in all acquisition of possession. But in the case put, there is something else which is only accidentally united with this corporeal contact, namely, the physical possibility to operate immediately on the thing, and to exclude all others from doing so. That both these things concur in the case put, cannot be denied: that they are only accidentally connected with corporeal contact, follows from this, that the possibility can be imagined without the contact, and the contact without the possibility. As to the former case, he who can at any moment lay hold of a thing which lies before him, is doubtless as much uncontrolled master of it as if he actually had laid hold of it. As to the latter, he who is bound with cords has immediate contact with them, and yet one might rather affirm that he is possessed by than that he possesses them. This physical possibility then is that which as a fact must be contained in all acquisition of possession: corporeal contact is not contained in that notion, and there is no case in which a fictitious apprehension need be assumed.'

This clear exposition of a principle of Roman law is applicable to all systems of jurisprudence which have received any careful elaboration, for the principle is in its nature general. It may be that the expounders of our law have not always clearly seen this principle, even when they have recognised it; and it may be that they have not always acted upon it. Still it will appear from various cases that the physical possibility of operating on a thing is the essential character of the acquisition of possession in English law. In the case of Ward *v.* Turner (2 Vez., 431) it was held by Lord Hardwicke that delivery of the thing was necessary in a case of 'donatio mortis causâ,' and delivery of receipts for South Sea Annuities was not held sufficient to pass the ownership of the annuities. In his judgment, Lord Hardwicke observed, 'delivery of the key of bulky things, where wines, &c. are, has been allowed a delivery of the possession, because it is the way of coming at the possession, or to make use of the thing; and therefore the key is not a symbol, which would not do.' In one of his chapters (§ 16, *Apprehension beweglichen Sachen*) Savigny uses the very same example of the key, showing that it is not a symbol, but the means of getting at things which are locked up, and therefore the delivery of the key of such things, when they are sold, is a delivery of the possession. (See the cases in the *Digest* cited by Savigny, p. 209.)

In a case (Williams *v.* Bosanquet, 1 Br. and B., 238) where a lease had been assigned by the lessee to a mortgagee as a security, the mortgagee was held liable to pay the rent, though he had never taken actual possession of the premises. The safest ground of this judgment seems to be that the contract of the lessor is with the lessee and his assigns, and the mortgagee is the assign of the lessee; it is therefore a contract between the lessor and the mortgagee; and as the lessee is liable to pay the rent though he never takes actual possession, so must the assignee be liable even if he does not take possession. Whether the assignee is also mortgagee or not, makes no difference as to this question. But it was also stated in the judgment (p. 263) that 'legal possession,' that is, acceptance of the thing assigned by acceptance of the assignment, is 'equivalent to actual entry,' that is, to actual possession. This can only mean that such so-called legal possession, which is simply 'the right to possess,' must be considered the same as actual possession, so far as the liabilities of the owner of such lease are concerned. But such possession is not equivalent to actual possession for the purpose of preventing the Statute of Limitations from running against the assignee, for the statute views the commencement of such legal possession as the commencement of the time when the assignee ought to take actual possession.

Opinions may vary as to what shall be the evidence of that physical possibility which is the characteristic of apprehension; but it can hardly be disputed that this is the principle to which particular cases must be referred. 'All possession then depends on the consciousness of unlimited physical dominion; in order to which there must be the will (animus) to treat the thing as our own; and there must be the physical conditions of that possibility (corpus), the consciousness of which is necessary.' (Savigny, p. 228.) Possession may be acquired through a man's agent, as well as by the man himself who wills to possess.

The animus which is necessary to the possession may often be inferred from the acts. When, in the case supposed, the vendor gives the key to the buyer, it must be assumed that delivery is intended on one side and the taking of possession on the other. If a man buys a cask of wine in a merchant's cellar, and puts his mark on it, this is no taking possession, but the object is to identify his property; if he marks timber lying in an open place, which he has purchased, this is a taking possession.

The principle seems to apply to choses in action. The question often arises in the cases of a wife's choses in action, what shall be considered a reduction of them into possession by the husband. In this case it is not necessary to a reduction into possession, that the husband shall actually have material contact of the thing; but he must have acquired such a power over it as will prevent any other person from getting it. If he has not done this, he has not reduced it into his possession. If a promissory note is given to a wife, and the husband only receives the interest on it during his life, it will belong to the wife if she survives him. (Nash *v.* Nash, 2 Mad.) If stock in the funds be bequeathed to a married woman, and the executor transfer it into her name, in which it continues till her husband's death, it devolves to the wife if she survives him. It seems that if a husband can sue alone for his wife's chose in action (which he can do if it accrue to her during the coverture), and if he obtain a judgment before he dies, that will entitle his personal representatives to the benefit of it; and probably a decree of a court of equity in favour of a husband, in right of his wife, would, if he dies before he receives the thing, entitle the husband's personal representatives to the benefit of the decree. ('Forbes *v.* Phipps, 1 Eden, 502; Jarman, *Settlements*, 'Precedents,' vol. ix., p. 22.)

It is still doubtful whether the assignment by a husband of his wife's immediate choses in action is a reduction into possession. It is very difficult to comprehend on what principle it should be considered a reduction into possession, except in the case of bills of exchange or promissory notes, on which the assignee sues in his own name. In the case of the husband's bankruptcy, the assignees are not entitled to the property unreduced into possession, against the surviving wife. (Jarman, *Settlements*, 'Precedents,' vol. ix.)

According to Blackstone (ii. 13), 'actual occupation of land without any right is *bare possession*, but such actual possession is *primâ facie* evidence of a legal title in the possessor, and it may in time become a perfect title.' This is properly the right of possession, that right which presupposes the condition of legal possession. Blackstone's 'right of possession,' which he speaks of in the same chapter, is the owner's right to possess, when he does not actually possess. The singular confusion of this chapter, and particularly of the third section, in which the author treats of the 'mere right of property, without either possession or even the right of possession,' that is, the right to possess, is not wholly due to the author, but partly belongs to the old system of our law and to the various legal remedies formerly applicable to the recovery of land. (See also Blackstone, iii., c. 10, 'On Possessory Actions,' &c.) In the case of personal chattels, 'right of possession' is sometimes used by the judges to signify the right to possess, as distinguished from actual possession. (Bloxam *v.* Sanders, 4 B. and C., 948.) But the English law admits a right of possession' as distinct from property and from the right to possess; as for instance, in the case of a man finding a thing, 'who has such a property as will enable him to keep it against all but the rightful owner.' The law therefore admits a right founded on the antecedent condition of a lawful possession only, or, as it is sometimes called, a bare possession. In like manner as to land, a *bare possessor* can maintain an action of trespass against a wrong doer.

POST-OBIT BOND (*Post Obitum*, Lat.), a bond given for the purpose of securing a sum of money, the condition of which is, that the money shall be paid on the death of some person.

POST-OFFICE.—*History*. Correspondence is the offspring of advanced civilization. When the state of society in this country anterior to the seventeenth century is considered, there can be little surprise that we hear nothing of a post-office before that period. Few of the motives to written communication could be said to exist. Each district of the country supplied its own wants. The little foreign trade which flourished was conducted between the English buyer and the foreign seller in person, at the port where the import was made. Literature and science dwelt only in the convent or the cell. There was little absence from the domestic hearth, excepting that of the fighting man following the service of his lord; but neither the serf nor his master had the power, even if they had the will, to write letters. The business of the state only demanded correspondence. The king summoned his barons from all quarters of the kingdom by letters or writs, and held frequent communication with his sheriffs, to collect his parliament together, to muster his forces, to preserve his peace, to fill his treasury. The expenses of the establishment of Nuncii, charged with the conveyance of letters, formed a large item in the charges of the royal household. As early as the reign of King John, the payments to Nuncii for the carriage of letters may be found enrolled on the Close and Misæ-Rolls, and these payments may be traced in an almost unbroken series through the records of subsequent reigns. Nuncii also formed part of the establishment of the more powerful nobles. In a wardrobe account of 27th year of Edward I., we find a specimen of the mode in which the payment is entered:—'x die Januarii nuncio Domini Regis de Hastang redeunti ad eundum dominum suum cum litteris Regis, pro expensis suis sic redeundo—xiii.' As correspondence grew, it is easy to see that economical arrangements for its transmission would grow likewise. The Nuncius of the time of King John was probably obliged to provide his own horse throughout his journey; whilst in the reign of Edward II. he was able, and found it more suitable, to hire horses at fixed *posts* or stations. In 1481, Edward IV., during the Scottish war, is stated by Gale to have established at certain posts, 20 miles apart, a change of riders, who handed letters to one another, and by this means expedited them 200 miles in two days. It would seem that the posts, at which relays of riders and horses were kept, were wholly private enterprises; but that when their importance became felt and appreciated, the state found it both politic and a source of profit to subject them to its surveillance. Before any substantive evidence appears of the superintendence of the posts by the government, the superscription often met with, of 'haste poste haste,' on letters written at the close of the fifteenth and beginning of the sixteenth centuries, is sufficient to show that the posts had become the customary channel for transmitting letters in the speediest way.

A statute in 1548 (2 and 3 Edw. VI., c. 3) fixed a penny a mile as the rate to be chargeable for the hire of post-horses. In 1581, one Thomas Randolph is mentioned by Camden as the chief postmaster of England; and there are reasons for concluding that his duties were to superintend the posts, and had no immediate connection with letters. The earliest recital of the duties and privileges of a postmaster seems to have been made by James I. The letters patent of Charles I. in 1632 (*Pat.*, 8 Car. I., p. i., m 15 d; *Fœdera*, vol. 19, p. 385) recite that James constituted an office called the office of postmaster of England for foreign parts being out of his dominions. This functionary was to have 'the sole taking up, sending, and conveying of all packets and letters concerning his service, or business to be despatched into forraigne parts, with power to grant moderate salaries;' the office was graunted to Mathewe le Quester, and Mathewe le Quester his son: all others were publiquely prohibited that they should not directly or indirectly exercise or intrude themselves: the said M. le Quester made and substituted William Frizell and Thomas Witherings his deputies, and his Majesty accepted the substitution. The king, 'affecting the welfare of his people, and taking into his princely consideration how much it imports his state and this realm that the secrets thereof be not disclosed to forreigne nations, which cannot be prevented if a promiscuous use of transmitting or taking up of forreigne letters and packetts should be suffered,' forbids all others from exercising that which to the office of such postmaster pertaineth, at their utmost perils.

In 1635 a proclamation was made 'for settling of the letter-office of England and Scotland.' It sets forth 'that there hath been no certain or constant intercourse between the kingdoms of England and Scotland;' and commands 'Thomas Witherings, Esq., his Majesty's postmaster of England for foreign parts, to settle a running post or two, to run night and day between Edinburgh and Scotland and the City of London, to go thither and come back in six days.' Directions are given for the management of the correspondence between post-towns on the line of road and other towns which are named, and likewise in Ireland. All postmasters are commanded 'to have ready in their stables one or two horses:' 2½*d.* for a single horse and 5*d.* for two horses per mile were the charges settled for this service. A monopoly was established, with exceptions in favour of common known carriers and particular messengers sent on purpose, most of which have been preserved in all subsequent regulations of the Post-office. In 1640 a proclamation was made concerning the sequestration of the office of postmaster for foreign parts, and also of the letter-office of England, into the hands of Philip Burlamachy of London, merchant; but in 1642 it was resolved by a committee of the House of Commons that such sequestration was 'a grievance and illegal, and ought to be taken off,' and that Mr. Wytherings ought to be restored. As late as 1644 it appears that the postmaster's duties were not connected directly with letters. A parliamentary resolution entered on the Journals of the Commons states that 'the Lords and Commons, finding by experience that it is most necessary, for keeping of good intelligence between the parliament and their forces, that post stages should be erected in several parts of the kingdom, and the office of master of the posts and couriers being at present void, ordain that Edmund Prideaux, Esq., a member of the House of Commons, shall be, and is hereby constituted, master of the posts, messengers, and couriers.' 'He first established a weekly conveyance of letters into all parts of the nation, thereby saving to the public the charge of maintaining postmasters to the amount of 7000*l.* per annum.' (Blackstone.) An attempt of the Common Council of London to set up a separate Post-office, in 1649, was checked by a resolution of the House of Commons, which declared 'that the office of postmaster is, and ought to be, in the sole power and disposal of parliament.'

But the most complete step in the establishment of a Post-office was taken in 1656, when an act was passed 'to settle the postage of England, Scotland, and Ireland. This having been the model of all subsequent measures, induces us to give something more than a passing notice of it. The preamble sets forth 'that the erecting of one General Post-office for the speedy conveying and recarrying of letters by post to and from all places within England, Scotland, and Ireland, and into several parts beyond the seas, hath been and is the best means not only to maintain a certain and constant intercourse of trade and commerce between all the said places, to the great benefit of the people of these nations, but also to convey the publique despatches, and to discover and prevent many dangerous and wicked designs which have been and are daily contrived against the peace and welfare of this commonwealth, the intelligence whereof cannot well be communicated but by letter of escript.' It also enacted that 'there shall be one Generall Post-office, and one officer stiled the postmaster-generall of England and comptroller of the Post-office.' This officer was to have the horsing of all 'through' posts and persons 'riding in post. Prices for letters, both English, Scotch, Irish, and foreign, and for post-horses, were fixed. All other persons were forbidden to 'set up or imploy any foot-posts, horse-posts, or pacquet-boats.' These arrangements were confirmed in the first year of the Restoration by an act which was repealed 9 Anne, c. 11. In 1683, a metropolitan penny-post was set up, the history of which is given at length in the 'Ninth Report of the Commissioners of Post-office Inquiry.' From 1711 to 1838, upwards of 150 acts affecting the regulations of the Post-office were passed. In the first year of Her present Majesty ninety-nine of these were repealed, either wholly or partially, and the following acts were passed, by which the whole department of the Post-office was regulated:

For the management of the Post-office, c. 33.

The regulation of the duties of postage, c. 34.

For regulating the sending and receiving of letters and packets by the post free from the duty of postage, c. 35.

For consolidating the laws relative to offences against the Post-office, and explaining certain terms and expressions, c. 36.

A mere enumeration of the titles of all the acts affecting the Post-office would occupy a considerable space An account even of these four last-mentioned acts must be dispensed with, and the reader referred to the acts themselves. Their enactments have been abrogated, to a great extent, by the adoption of Mr. Rowland Hill's plan of uniform postage, which we shall notice hereafter. This measure, which has placed the Post-office, at the time we are now writing, in a state of total transition, so that what is in practice to-day falls into disuse on the morrow, was carried into effect by an act passed in 1839, 2 and 3 Vic., cap. 52, which conferred temporary powers on the Lords of the Treasury to do so, and was subsequently confirmed by an act 3 and 4 Vic., c. 96, passed 10th August, 1840.

Rates of Postage.—The first establishment of a rate of postage for carrying letters occurs in 1635, in the proclamation already described. The rates were fixed as follows:—

Under 80 miles	2*d.*	single letter.
Between 80 miles and 140 miles .	4	„
Above 140 miles	6	„
On the borders and in Scotland .	8	„

'Two, three, four, or five letters in one packet, or more, to pay according to the bigness of the said packet.'

The rates, both inland and foreign, fixed by the ordinance of the Commonwealth in 1656, are therein fully detailed. Letters above two sheets were charged by weight. In most cases the rates vary but little from those fixed in the 12 Car. I., the principal of which were as follows:—

Letter not exceeding one sheet, to or from any place not exceeding 80 miles, 2*d.*; above 80 miles, 3*d.* From London to Berwick, 3*d.*; to Dublin, 6*d.* Letters of two sheets were charged double. By the 9 Anne, c. 11, a penny was added to several of the rates previously established; a letter from London to Edinburgh was charged 6*d*. The additions subsequently made appear in the following table:—

A Table showing the Scale of Distances according to which the Postage of Great Britain was charged, with the Rates levied for those Distances, from the year 1710 to Dec. 5, 1840.

SCALE OF DISTANCES.	1710.	1765.	1784.	1797.	1801.	1805.	1812.
ENGLAND.	*d.*	*d.*	*d.*	*d.*	*d.*	*d.*	*d.*
From any Post-office in England or Wales to any place not exceeding 15 miles from such office .	3	1	2	3	3	4	4
For any distance above 15 miles, and not exceeding 20 miles	3	2	3	4	4	5	5
Above 20 miles, and not exceeding 30 miles. .	3	2	3	4	4	5	6
— 30 . . . . 50 — . .	3	3	4	5*d*. between 30 and 60 miles; 6*d*. between 60 and 100 miles; 7*d*. between 100 and 150 miles; 8*d*. above 150 miles.	5	6	7
— 50 . . . . 80 — . .	3	3	4		6	7	8
— 80 . . . . 120 — . .	4	4	5		7	8	9
— 120 . . . . 170 — . .	4	4	5*d*. under 150 m. 6*d*. above 150 m.		8	9	10
— 170 . . . . 230 — . .	4	4	6	8	9	10	11
— 230 . . . . 300 — . .	4	4	6	8	10	11	12
— 300 . . . . 400 — . .	4	4	6	8	11	12	13
— 400 . . . . 500 — . .	4	4	6	8	12	13	14
And so on in proportion, the postage increasing progressively 1*d*. for a single letter for every like excess of distance of 100 miles.							

These rates were applied to general-post letters passing from one post-town to another post-town. The principle of the rating was to charge according to the distance which the conveyance travelled, until the year 1839, when the direct distance only was charged. A single letter was interpreted to mean a single piece of paper, provided it did not exceed an ounce in weight. A second piece of paper, however small, or any inclosure, constituted a double letter. A single sheet above an ounce was charged with fourfold postage. After a fourfold charge, the additional charges advanced by weight.

In Scotland, letters, when conveyed by mail-coaches only, were subject to an additional halfpenny. Letters passing between Great Britain and Ireland were subject to the rates of postage charged in Great Britain, besides packet rates, and Menai, Conway Bridge, or Milford rates.

Between 1814 and 1839, the rates in Ireland were as follows:—

Distances in Irish Miles.	Rates for Single Letters.	Distances in Irish Miles.	Rates for Single Letters.
7	2*d*.	95	9*d*.
15	3	120	10
25	4	150	11
35	5	200	12
45	6	250	13
55	7	300	14
65	8		

The Postmaster-general had authority to establish penny posts for letters not exceeding in weight four ounces, in, from, or to, any city, town, or place in the United Kingdom (other than London or Dublin), without any reference to the distance to which the letters are conveyed.

The principle which guided the department in establishing penny posts, was to select small towns and populous neighbourhoods, not situated in the direct lines of general-post conveyances, and desirous of obtaining that facility, wherever such penny post did not afford the means of evading the general post, and promised to yield a return that would pay for its maintenance. The rule was to consider whether the receipts on the first setting up of the post would pay about two-thirds of the charge. The Post-office took its chance of the remainder being made good. There is a penny post for Dublin, the limits of which the Postmaster-general has authority to alter.

The London Twopenny Post extended to all letters transmitted by the said post in the limits of a circle of three miles' radius, the centre being the General Post-office in St. Martin's le Grand; which limits the Postmaster-general had authority to alter. The London Threepenny Post extended to all letters transmitted by the said post beyond the circle of three miles' radius, and within the limits of a circle of twelve miles' radius, the centre being the General Post-office.

The Select Committee of the House of Commons in 1838 and 1839, which investigated Mr. Rowland Hill's plan, reported the following to be the average rates of postage:—

Average rates, Multiple Letters being included and counted as Single.

	d.	*d.*
Packet and ship letters . .	23·1562 = nearly	23¼
——— and inland general-post letters	9·7065 = nearly	9¾
Ditto, ditto, and London 2*d*. and 3*d*. post letters . . .	8·4006 = nearly	8½
Ditto, ditto, ditto, and country 1*d*. post letters	7·6074 = little more than	7½
Inland general-post letters only	8·6502 = nearly	8¾
Ditto and London 2*d*. and 3*d*. post letters	7·4688 = nearly	7½
Ditto, ditto and country 1*d*. post letters	6·7414 = nearly	6¾

Average rates, Multiple Letters being excluded.

Single inland general-post letters	7·7445 = nearly	7¾
Ditto and London 2*d*. and 3*d*. post letters	6·8202 = little more than	6¾
Ditto, ditto, and country 1*d*. post letters	6·2166 = nearly	6¼

Franking.—As early as a post-office was established, certain exemptions from the rates of postage were made. Parliamentary franking existed in 1666. An entry is registered on the Journals of the House of Commons on 19th October, 1666, 'That Edward Roberts be sent for in custody of the serjeant-at-arms or his deputy to answer his abuse and breach of privilege in exacting money of the members of this House for post letters.' In the paper bill which granted the post-office revenue to Charles II. a clause provided that all the members of the House of Commons should have their letters free, which clause was left out by the lords, because no similar provision was made for the passing of their letters, but a compromise was made on the assurance that their letters should pass free.

In 1735 the House of Commons prosecuted some investigations into the subject, which appear on the Journals. Again, in 1764 (4 Geo. III.), a committee was appointed 'to inquire into the several frauds and abuses in relation to the sending or receiving of letters and parcels free from the duty of postage.' Among various abuses proved to exist, it is related that 'one man had in the course of five months counterfeited 1200 dozen of franks of members of parliament, and that a regular trade of buying and selling franks had been actually established with several persons in the country.' Resolutions restricting and regulating the privilege were passed. From time to time the privilege was extended, until it was finally abolished, with a very few exceptions, on 10th January, 1840.

Seven millions of franks, out of sixty-three millions of general-post letters, including franks, were estimated in 1838 to pass through the Post-office annually. The relative quantities of these several documents are given in the 'Third Report of the Commons' Committee;' as follows:—

				Single Letters.
56,000,000	of general-post chargeable letters, equivalent at	1⅛	to	63,000,000
4,813,448	parliamentary franks	2	to	9,626,896
2,109,010	official franks	8	to	16,872,080
77,542	copies of the statutes	13	to	1,008,046
63,000,000				90,507,022

The privileged letters therefore, reduced to the standard of single letters, amounted to above 30 per cent. of the whole number of letters transmitted by the general post.

The average weight of a single chargeable letter was about 3-10ths of an ounce; the average weight of a parliamentary frank about 48-100ths of an ounce; that of an official frank 1·9376 oz., or nearly two ounces; and that of a copy of a public statute 3·1129 oz. Had they been liable to the then existing rates, they would have contributed in the following proportions to the revenue:—

	Number.	Rate per Letter.	Revenue.
		d.	£.
Parliamentary franks	4,813,448	17·392	348,814
Official franks	2,109,010	70·209	616,965
Statutes distributed	77,542	112·795	36,443
Totals	7,000,000	...	1,002,222

Newspapers with a few exceptions pass free of postage. All franking is now altogether abolished.

Revenue.—The statistics of the Post-office revenue are far from complete. In the early period of the Post-office establishment, and before 1716, only a few scattered accounts can be collected. In 1653 the annual revenue was farmed for 10,000*l.*, and in 1659 for 14,000*l.* (Journals of the Commons.) In 1663 it was farmed for 21,500*l.* annually, and the amount settled on the Duke of York. In 1674 the farming of the revenue yielded 43,000*l.* In 1685 it produced 65,000*l.* Parliament resumed the grant after 1688, though the king continued to receive the revenue. In 1711 the gross revenue was reckoned at 111,426*l.* From 1716 to 1733 the average yearly net revenue was 97,540*l.*, founded upon 'a certain account and not an estimate.' (Commons *Journals*, April 16, 1735.) In the Postage Reports of 1838 (vol. ii., App., p. 176; vol. i., p. 511) are accounts showing the gross receipt, charge of management, net receipt, and rate per cent. of collection in Great Britain from 1758 to 1837, and in Scotland and Ireland from 1800 to 1837. The accounts for a few years will serve to show its progress.

GREAT BRITAIN.

Years ended 5 April.	Gross Receipt.	Charges of Management.	Net Receipt (returns deducted).	Rate per cent. of Collection.		
	£	£	£	£	*s.*	*d.*
1758	222,075	148,345	73,730	66	15	11
1769	305,058	140,298	164,760	45	19	9
1779	402,918	263,670	139,248	65	8	9
1786	506,500	220,525	285,975	43	10	9
1799	1,012,731	324,787	657,388	32	1	4
1816	2,193,741	594,045	1,526,527	27	1	6
1837	2,206,736	609,220	1,511,026	27	12	1

SCOTLAND.

Years.	Gross receipts.			Charges of Collection.			Net income.			Rate per cent. for collection.
	£	*s.*	*d.*	£	*s.*	*d.*	£	*s.*	*d.*	£
1800	100,651	14	4	16,896	8	0	83,755	6	4	16¾
1837	220,758	13	10	59,945	7	1	160,813	6	9	27

IRELAND.

			Returns deducted.			
1800	84,040	59,216	24,824	70	9	2
1837	255,070	95,548	134,809	37	9	2

The revenue for the United Kingdom for the years ended 5 January, 1838 and 1839, was as follows:—

Years ended 5 Jan.	Gross receipts.	Charges of collection.	Returns.	Net receipts.	Rate per cent. of collection.		
	£	£	£	£	£	*s.*	*d.*
1838	2,462,269	669,940	122,531	1,669,798	27	4	1
1839	2,467,216	669,756	120,938	1,676,522	27	2	11

The Select Committee on Postage, in 1838, instituted the following comparison between the Post-office revenue of the six years ending 5th January, 1838, and that of six years ending 5th January, 1821.

See Appendix to Report I., p. 503.	GROSS REVENUE, Excluding repayments. 1815 to 1820 inclusive.	GROSS REVENUE, Excluding repayments. 1832 to 1837 inclusive.	NET REVENUE, After deducting cost of management. 1815 to 1820 inclusive.	NET REVENUE, After deducting cost of management. 1832 to 1837 inclusive.
	£	£	£	£
	2,273,843	2,175,292	1,598,295	1,531,823
	2,323,835	2,190,181	1,619,196	1,553,425
	2,186,634	2,209,439	1,537,505	1,513,052
	2,099,225	2,243,294	1,433,871	1,564,458
	2,151,213	2,350,603	1,467,533	1,645,835
	2,108,833	2,339,738	1,522,640	1,658,479
Totals of the six years	13,143,583	13,508,547	9,179,040	9,467,077
Average of the six years	2,190,597	2,251,424	1,529,840	1,577,846
Increase at the end of seventeen years	60,827	....	48,006	....
Annual average increase	3,578	....	2,923	....

It thus appeared that on an average gross revenue of 2,190,597*l.* there had been in seventeen years a positive increase of 60,827*l.*, averaging only 3578*l.* yearly, or little more than 1½ per thousand, though the advance had been rapid in population, and still more so in wealth, industry, and trade.

Establishment, Cost of Management, &c.—The head of the Post-office is styled the Postmaster-General, under whose authority are placed all the Post-offices in the United Kingdom and the colonies. The office was jointly held by two persons until the last few years. It is considered a political one, and the holder relinquishes it with a change of ministry; but the postmaster-general has not a seat in the cabinet. The Commissioners of Post-office Inquiry (4th Report) recommended that the office should be exercised by three permanent commissioners; and a bill passed the Commons to give effect to the recommendation, but was thrown out by the Lords. The last return of the force of the establishment was made in 1835, and was as follows:—

Establishment.

1. Postmaster-General.

	London.	Dublin.	Edinburgh
Number of persons employed in secretary's office	17	7	4
Mail-coach office	12	2	
Solicitor	1	1	1
Receiver-general	9	3	Cashier's office 2
Accountant-general	15	7	5
Surveyors	7	3	2
Ship-letter office	8		
Dead-letter office	18	8	3
Foreign office	16		
Inland office	80	32	23
Inspectors of letter-carriers	4	2	1
Messengers	30	8	
General-post letter-carriers	281		
Mail guards	220	82	
Sea-mail guards	8		
Housekeeper, bagmen, watchmen, &c.	23	14	
Twopenny-post	54		
Twopenny-post letter-carriers	464	89	55
Total	1337	258	97
Expenses	£96,234 17 10	£18,394 19 2	£9,735 6

Parl. Paper., No. 442 (1835).

In 1831 and 1832 the chief offices of London, Dublin, and Edinburgh were re-modelled by the duke of Richmond, then postmaster-general. The separate office of postmaster-general for Ireland was abolished, and other changes were made, which were estimated to reduce the expenses above 4700*l.* per annum. In London the saving was estimated at 6448*l.* per annum: a secretary at Dublin and at Edinburgh is chief executive officer for the respective countries.

The metropolitan General Post-office was removed in 1829 from Lombard-street to St. Martin's-le-Grand. It is the head-quarters of all post-office business. All accounts of the collection of the revenue and the expenditure are rendered there.

The number of persons employed in London in the dispatch of general-post letters only in the evening is about 290. In the morning, including newspapers, about 380. In the evening about 180 letter-carriers are employed on newspapers, the nightly average of which is about 50,000. On Saturdays the numbers often exceed 100,000. Constant additions are being made to the number of post-offices throughout the kingdom. At the present time the following, considering posts formerly called penny-posts, 'fifth-clause posts,' and sub-offices as post-offices, may be taken to be about the numbers:—

	Post-Offices.	Sub-Offices.	Penny-posts.	Total.
England .	650	190	1090	1930
Scotland .	220	105	230	555
Ireland .	330	105	200	635

Every post-office in the United Kingdom has direct communication respectively with the chief offices in London, Dublin, and Edinburgh.

The operations of the Post-office belonging to the dispatch of letters before the introduction of Mr. Hill's plan, but which are thereby subjected to some modification, consisted in—1, facing or placing one way all the addresses of the letters and stamping them, to show the date of their receipt; stamping being performed with a hand-stamp at the rate of 200 letters per minute; 2, sorting according to the different mail-routes; 3, examining and taxing the letters with the various charges; 4, re-sorting according to the different post-towns; 5, telling, that is, making out bills for the unpaid letters against the different deputy-postmasters.

The duty of the London General Post-office in the receipt of letters consisted in unloading the mails and delivering the letters, that is to say—1, in opening the bags, of which there are 700, and in checking the deputy-postmasters' accounts for paid letters, one person examining a bag in one minute and a half; 2, sorting into districts; 3, telling, that is, making out bills against every letter-carrier; 4, delivering; the letter-carriers return by a certain time, and pay the money charged against them to the receiver-general.

The Commons' Committee, in 1838, prepared the following analysis of the

Cost of Management for the United Kingdom.

	Total.	In these Three Columns the Items of Cost are classed according to the principle suggested by Mr. Hill, the data being taken from the Post-office Returns, Nos. 41 and 42, pp. 220 and 221, App. Rep. II.		
		Cost of Distribution within the United Kingdom.		Foreign and Colonial Expenses and Superannuation Allowances.
		Cost of Transit.	Cost of Establishment.

	698,632 2 2	Total Cost of Distribution in United Kingdom . . .	575,384 13 1	123,247 9 1

These accounts show that about four-fifths of the charges consist of the cost of distributing letters in the United Kingdom. Transit costs two-fifths, and the establishment two-fifths. The maintenance of the post between this country and the colonies and foreign countries, the inland post in certain colonies, and other charges, make up the remaining fifth. But these accounts are not altogether complete, because the expense of those packets controlled by the Admiralty is included in the Navy Estimates, and cannot be separated. And as the penny stamp on newspapers was retained as a postage, about 185,000*l.* should be carried to the account of the Post-office receipts. These accounts are of course subject to change yearly. The employment of railroads has added much, since the above analysis was made, to the mileage charges.

No accounts of the number of documents passing through the Post-office were kept until very lately. Founded upon a very careful examination of the best data, the numbers were estimated by the Commons' Committee, in 1838, to be as follows:—

Chargeable letters—

General Post, inclusive of foreign letters, and reckoning double and triple letters as single	57,000,000
2*d.* and 3*d.* post letters	12,500,000
Country penny-post letters	8,000,000
	77,500,000
Franks	7,000,000
Newspapers	44,500,000
	129,000,000

A more detailed estimate, the result of very elaborate calculations, is appended to the 'Report of the Commons' Committee' which is here subjoined—

Description of Letters.	Yearly Number of Letters.	Average rate per Letter. *d.*	Yearly Revenue. £.
Packet and ship letters	3,523,572	23·1562	369,340
General Post inland letters above 4*d.*	46,378,800	9·2224	1,782,191
Ditto, not exceeding 4*d.*	5,153,200	3·5	75,151
London local-post letters	11,837,852	2·3266	114,753
Country penny-post letters . . .	8,030,412	1	33,483

Newspapers . .	44,500,000	...	...
Total of documents transmitted by post	126,423,836	...	2,374,923
Unappropriated			4,641
Total revenue from letters, 1837			2,379,564

See Notes to *Postage Report*, pages 4 and 6.

The chargeable letters in the mails leaving London were found to weigh only 7 per cent. of the whole weight of those mails. The total weight of the chargeable letters and franks carried by the thirty-two mails leaving London was only 2912 lbs. Deducting one-half as the weight of the franks and franked documents, the weight of all the chargeable letters was only 1456 lbs., being 224 lbs. less than the weight which a single mail is able to carry. The average weight of the thirty-two mails was found to be as follows:—

Average of 32 Mails.	Pounds weight.	Per centage.
Bags weighed	68	14
Letters, including franked letters and documents	91	20
Newspapers	304	66
	463	100

The management of the conveyance of the mails by sea and land is subject, of course, to those constant changes which arise out of the improvements daily taking place in the various modes of transit. Certain packets are exclusively controlled by the Admiralty, to whose charge they were removed in 1837; others still remain with the Post-office. The Parliamentary Returns and Reports of various Commissioners on the subject of the Packet-Service are numerous. The most important are—'The Twenty-second Report of the Commissioners of Revenue Inquiry,' part 5, printed 1830, and the 'Sixth Report of the Post-office Commissioners on the Packet Establishments,' printed in 1836.

Contracts for the conveyance of the mail-bags to the Continent are made between the Post-office and the proprietors of certain steam-vessels. A contract has lately been entered into with Mr. Cunard at an expense of 60,000*l.* per annum to carry the mails twice a month for eight months and once a month for four months in first class steam-ships between Liverpool and British North America. The passage between Liverpool and Halifax has been performed in ten days. The Post-office moreover has power of sending a bag of letters in any private ship.

The inland correspondence is carried by railroads, by four horse and two-horse coaches; by cars in Ireland, by single-horse carts, on horseback, and foot.

Number of miles travelled over in England and Scotland by the mail-coaches in the following years, was as follows:—

1834 . .	5,911,006	1837 . .	6,643,217
1835 . .	5,931,218	1838 . .	7,204,295
1836 . .	6,233,478	1839 . .	7,377,857

And a Parliamentary Return, printed 1836 (No. 364), presented the following account of the speed and cost of the mail-coaches:—

	England. Miles.	Ireland. Miles.	Scotland Miles.
Greatest speed travelled per hour . . .	10⅝	9½	10½
Slowest, „ „	6	6⅞	7
Average speed „ „	8⅞	8¼	8¼
	Per mile.	Per English mile.	Per mile.
Average mileage for 4-horse mails . .	1⅞*d.*	2⅞*d.*	1⅛*d.*
Ditto for 2-horse do. .	1¾	1¼	2¼

Since this Return, in 1836, was made, the acceleration of the mails by the use of railroads has been nearly doubled, and most of the mail coaches out of London have been superseded by them. At the present time, upwards of a fourth of the whole correspondence of the United Kingdom is carried on the Birmingham Railroad. The mail between London and Edinburgh is now conveyed in thirty hours, partly by railway and partly by coach.

The present system of mail coaches owes its origin to Mr. Palmer. In 1784, Mr. Palmer, who was manager of the Bath and Bristol theatres, laid a plan before Mr. Pitt, which was adopted by the government, after much opposition from the functionaries in the Post-office. The greatest improvement in the transmission of the correspondence of the country was effected by this plan. Mr. Palmer found the post, instead of being the quickest, nearly the slowest conveyance in the country; very considerably slower than the common stage coaches. The average rate of speed did not exceed three miles and a half per hour. Whilst coaches left London in the afternoon and reached Bath on the following morning, the post did not arrive till the second afternoon. Slowness was not the only defect: it was also irregular, and very insecure. The robbery of the mail was very common. Mr. Palmer succeeded in perfecting the mail-coach system, and in greatly increasing the punctuality, the speed, and security of the post. At least 500 places obtained a daily delivery of letters, which before received them not oftener than three times in the week.

The net revenue before these changes had averaged for twenty years about 150,000*l.* a year. In ten years after Mr. Palmer's plan had been in work, the net revenue increased to 400,000*l.*; in twenty years it became 700,000*l.*; and in thirty years it had reached a million and a half, from which sum it can hardly be said to have advanced to the present time. The reader will find both the history and progress of Mr. Palmer's plan, of the Post-office opposition, and the subsequent proceedings arising out of his claims, fully related in Parliamentary Papers, printed by order of the House of Commons in 1807, 1808, and 1813.

Mr. Rowland Hill's plan.—In 1838 a plan calculated not only to increase the utility of the Post-office in the promotion of all the objects of civilization, but to change the whole management of the institution, was brought forward by Mr. Rowland Hill, a gentleman wholly unconnected with the department. It was at first privately submitted to the government, and subsequently published in a pamphlet under the title of 'Post-office Reform—its Importance and Practicability.' In a short period three editions were issued. The main features of Mr. Hill's plan, which, putting aside the merits of the suggestion of a uniform rate, is discussed with singular moderation, acuteness, caution, and sound reasoning, proposed to effect—1, a great diminution in the rates of postage; 2, increased speed in the delivery of letters; and, 3, more frequent opportunities for their dispatch. He proposed that the rate of postage should be uniform, to be charged according to weight, and that the payment should be made in advance. The means of doing so by stamps were not suggested in the first edition of the pamphlet, and Mr. Hill states that this idea did not originate with him. A uniform rate of a penny was to be charged for every letter not exceeding half an ounce in weight, with an additional penny for each additional ounce. Mr. Hill discovered the justice and propriety of a uniform rate in the fact that the cost attendant on the transmission of letters was not measured by the distance they were carried. He showed on indisputable data that the actual cost of conveying letters from London to Edinburgh, when divided among the letters actually carried, did not exceed one penny for thirty-six letters. Independently of its fairness, the obvious advantages of simplicity and economical management were strongly in favour of a uniform rate.

The publication of this plan immediately excited a strong public sympathy in its favour, and especially with the commercial classes of the City of London. Mr. Wallace moved for a select committee to inquire into its merits on the 9th May, 1837; but the motion fell to the ground. On the 30th May, 1837, Lord Ashburton, upon presenting a petition from some of the most eminent merchants, bankers, men of science, and others in the metropolis, to the House of Lords, spoke strongly in favour of the plan. In the December of the same year the government assented to the appointment of a select committee to inquire into and report upon the plan. A society of merchants was forthwith formed in the City of London to furnish evidence of the evils of the high rates of postage, and the insufficiency of the Post-office management in answering the wants of the present times. The subject began to excite much interest throughout the country. In the session of 1837 five petitions were presented to the House of Commons in favour of the plan. In 1838 upwards of 320 were presented, of which number seventy-three emanated from town-councils, and nineteen from chambers of commerce. After sitting upwards of sixty-three days, and examining Mr. Rowland Hill and eighty-three witnesses, besides the officers of the departments of the Post-office and the Excise and Stamps offices, the committee presented a most elaborate Report in favour of the whole plan, confirming by authentic and official data the conclusions which Mr. Hill had formed from very scanty and imperfect materials. The Committee summed up a very long Report as follows:—

'The principal points which appear to your Committee to have been established in evidence are the following:—

'The exceedingly slow advance, and occasionally retrograde movement, of the Post-office revenue during the period of the last twenty years. The fact of the charge of postage exceeding the cost in a manifold proportion. The fact of postage being evaded most extensively by all classes of society, and of correspondence being suppressed, more especially among the middle and working classes of the people, and this in consequence, as all the witnesses, including many of the Post-office authorities, think, of the excessively high scale of taxation. The fact of very injurious effects resulting from this state of things to the commerce and industry of the country, and to the social habits and moral condition of the people The fact, so far as conclusions can be drawn from very imperfect data, that whenever on former occasions large reductions in the rates have been made, those reductions have been followed in short periods of time by an extension of correspondence proportionate to the contraction of the rates.

'And as matter of inference from fact, and of opinion,

'That the only remedies for the evils above stated are, a reduction of the rates, and the establishment of additional deliveries, and more frequent dispatches of letters.

'That owing to the rapid extension of railroads, there is an urgent and daily increasing necessity for making such changes.

'That any moderate reduction in the rates would occasion loss to the revenue, without in any material degree diminishing the present amount of letters irregularly conveyed, or giving rise to the growth of new correspondence.

'That the principle of a low uniform rate is just in itself; and when combined with pre-payment, and collection by means of a stamp, would be exceedingly convenient, and highly satisfactory to the public.'

The appearance of the Committee's Report seemed to inspire the whole country with confidence in the plan. Petitions in its favour amounting to 2000 were presented to both houses of parliament in the session of 1839. The late postmaster-general, the duke of Richmond, advised the government to adopt it; and the chancellor of the exchequer brought forward a bill to enable the Treasury to carry the plan into effect, which was carried by a majority of one hundred in the House of Commons, and passed into law on the 17th August, 1839. In the following month an arrangement was made which secured Mr. Rowland Hill's superintendence of the working out his own measure. On the 5th December, 1839, as a preparatory measure, to accustom the department to the mode of charging by weight, the inland rates were reduced to a uniform charge of 4*d.* per half ounce. The scale of weight for letters advanced at a single rate for each half ounce up to sixteen ounces. Other reductions were made in the packet rates; and the London district post was reduced from 2*d.* and 3*d.* to 1*d.* This measure continued in force until the 10th January, 1840, when a uniform inland rate of postage of 1*d.* per half ounce, payable in advance, or 2*d.* payable on delivery, came into operation. On this day parliamentary franking entirely ceased. On the 6th May stamps were introduced: only three of the proposed forms were ready at this time, the covers, envelopes, and labels. The warrants of the lords of the Treasury which authorised these changes were published in the London Gazette of the 22nd November, 28th December, 1839; 25th April, 1840. The effect of these changes on the revenue cannot at present be accurately shown; but it is estimated that the loss of net revenue on the first year will be above one million. Returns have been made which show the increase of letters to the time we are now writing. The number of letters which were actually counted for the week ending 24th November, 1839, before any changes took place, was 1,585,973 letters, including franks; for the week ending 22nd December, 1839, during the fourpenny rate, it was 2,008,687; and for the week ending 23rd February, 1840, 3,199,637. Thus the number of *chargeable* letters of all kinds increased 29 per cent. under the 4*d.* rate, and 121 per cent. (or, deducting the government letters, 117 per cent.) under the 1*d.* rate. The number of chargeable letters dispatched by the General Post increased 40 per cent. under the 4*d.* rate, and 169 per cent. (or, deducting the government letters, 165 per cent.) under the penny rate.

The following are the returns made to the House of Commons (printed, No. 501) of the number of letters for th whole kingdom since the 23rd February, 1840:—

Week ending	
22 March, 1840	...3,069,496
26 April, „	...2,954,866*
22 May, „	...3,138,035
21 June, „	...3,221,206

POSTING, from the French 'poste,' derived from the Low Latin word 'posta' (Ducange, *in verbo*), is so called from horses being placed at certain stations or posts, where they may be hired by individuals at their pleasure. The application of the words 'post' and 'postmaster' as well to the transmission of letters and the persons to whom this business is entrusted, as to stations where post-horses are kept, and the persons who own or have the care of them, is the cause of much confusion: and it frequently cannot be understood in reference to which branch early writers intend these terms to be applied. The ambiguity is not confined to the English language. Post-horses were first established by the governments on the continent of Europe in the thirteenth and fourteenth centuries for the conveyance of dispatches; they were occasionally employed for the conveyance of persons connected with such governments, and gradually by passengers in general. Posting continues in most countries to be carried on by the state, which retains the monopoly of supplying post-horses, and usually of forwarding mails and diligences: Great Britain and Ireland, and a part of Hungary, are the only exceptions. In the United States and British North America there is at present (1840) no posting, at least in the sense in which the term is commonly used; that is to say, a person cannot have his carriage conveyed in such a direction as he may wish, and hire fresh horses at convenient stages. He must engage an 'extra exclusive' in some principal town, and the same horses must convey him throughout his whole journey, unless another large town should lie on the road. This is the mode of travelling known on the Continent by the name of 'vetturino,' 'voiturier,' or 'Lohnkutscher.' The want of the power of posting is not so inconvenient as might be supposed, for the number of private carriages is not large, and in districts where there is much travelling, communication is usually facilitated by steam-boats, railways, and stage-coaches.

---

* Easter holiday week.

In *France* the government conduct all posting, and an authorised book is published fixing the number of horses to be used according to the number of persons to be conveyed and the shape of the carriage. We must refer to this book, in which all the regulations respecting this manner of travelling will be found. The charge for each horse is 15*d.* for a post of five English miles; there is an addition to this charge on entering large towns. The average rate of travelling is from five to six miles an hour.

In *Germany*, posts were first established by the Count de Taxis at his own expense, for which he was rewarded in 1616 by the emperor Matthias, who conferred on him and his successors the office of postmaster, and gave them the exclusive privilege of furnishing horses for the conveyance of letters and passengers throughout his dominions. This privilege is still retained by the descendants of Taxis in some of the small German states. The number of horses used is not at the discretion of the traveller, but, as in France, according to the quantity of persons and luggage to be conveyed and the shape of the carriage. The price is low, some of the government regulations are inconvenient, and the travelling is slow. (Murray's *Handbook for North Germany*, p. 188.)

In *Holland* the posting regulations introduced by the French still remain in force, and are nearly identical with those of France. A Dutch post of somewhat less than five English miles may be travelled with a pair of horses for about 3*s.* 4*d.* English; this sum does not include tolls, which are extremely high in that country. (Murray's *Handbook, North Germany.*)

In *Belgium* posting is under nearly the same regulations as in France: the cost of a pair of horses is about 1*s.* an English mile, post-boy included.

In *Switzerland* posting is confined to certain routes near the frontier. An authority is likely to be given by the diet for the general establishment of post-horses. (Murray's *Handbook for Switzerland.*)

In *Hungary* posting is principally in the hands of government; the cost for a pair of horses a little exceeds 3 florins a post. Between Vienna and Pesth there is likewise an independent posting establishment, the speculation of peasants who drive their own horses, and called 'Bauern (or peasants') post.' It is one-third cheaper, and at least twice as expeditious as the government posting; but travellers must find their own carriages, as post-caleches are not provided by the peasants. (Murray's *Handbook for South Germany*, and Paget's *Hungary*, i. 36.)

In *Italy* posting is found on the principal roads. The price, which is fixed by the respective governments, varies in the different states. It is charged by the post, a measure which is likewise variable. (Starke's *Guide Book*, p. 484.)

In *Spain* post-horses are provided by government on the main roads, but they are seldom used for the conveyance of private carriages on account of the frequent robberies of travellers who have not an escort, or who travel in small companies.

In *Russia* a traveller must obtain a 'Padaroshna,' or order from the governor of the place on all the postmasters on his intended route, enjoining them to supply him with a specified number of horses. The charge made for this order is afterwards deducted from the price paid for the horses. Posting costs from 4*s.* 6*d.* to 6*s.* English for four horses for twelve miles; the drivers get a trifle, a rouble (10*d.*) or half a rouble each for a stage. A traveller should furnish himself with a 'marche route.' There being no book of roads and posts, it is customary to apply to the clerks of the post-office before starting from Petersburg or Moscow, who, for a fee of 10 or 12 roubles, make out a list in Russian and Italian characters of all the posts on the line, with the number of versts between each. The low payment of postmasters by the emperor induces them continually to attempt extortion. The pace travelled is frequently very fast considering the nature of the country. (Bremner's *Russia*, p. 176, vol. ii.)

Posting is very generally established in England, but is now less used in consequence of the introduction of railways. In frequented and populous districts, change of horses may commonly be procured at intervals of from eight to twelve miles, and in the most remote and thinly inhabited at inns not more than from fifteen to twenty miles apart. The cost at which post-horses are bought is ordinarily greater than that of stage-coach horses; they are often employed to draw very heavy weights, and are used for long stages; besides, one at least in each pair must be a saddle as well as a draught horse: the average price of each horse may be stated at 17*l.* The trade is wholly in the hands of private speculators. The rate of travelling with post-horses varies according to the weight of the carriage and the number of horses employed; from eight to nine miles an hour may be stated as the average rate of a pair of horses under ordinary circumstances. The number of horses hired depends solely on the will and discretion of the party hiring, which are controlled by no legal regulation whatsoever. The payment is estimated per mile for each pair of horses, without reference to the number of persons conveyed, and a second pair of horses is charged at the same rate as the first; the payment to the postmaster does not include the driver, who expects a gratuity of about three pence a mile. Four horses is the greatest number ever required for one carriage. Sixteen or eighteen pence per mile is the usual price for each pair of horses, and, when the payment of postboys and turnpikes is added, a journey will be found to cost about twenty-two pence a mile. If a post-chaise or fly be required as well as post-horses, no additional charge is made on account of the carriage. The price of posting is nearly uniform throughout England, but there is considerable variation in the degree of goodness of the horses and chaises provided. On much-frequented roads, where there is generally competition in the posting trade, the accommodation is very superior to what is found at little-frequented inns, where an inferior description of post-horse is kept, which is often insufficiently fed because it is not frequently employed. One of the causes which account for the excess of price paid for posting in England above that on the Continent is the large amount of tax which is levied upon it. 1. A postmaster pays yearly 7*s.* 6*d.* for a licence. 2. For every chaise or four-wheeled carriage, 5*l.* 5*s.*; and for every two-wheeled carriage, 3*l.* 5*s.* annually. 3. Three pence a mile for each pair of horses. The last-mentioned duty is levied in the following manner:—An Excise officer delivers to the postmaster so many printed tickets, some for four horses, some for two, and some for one horse; the postmaster is required, when he sends out his horses, to fill in upon a ticket, on which is stated the number and his name, the date, and the number of miles which the horses are hired to travel: this ticket is left by the postboy at the first turnpike. The excise-officer periodically takes account of these tickets, which are returned to his office by the turnpike-keepers; he also compares them with the number issued to the postmaster, and if the postmaster cannot produce the correct balance which he should have in hand, he is fined 1*s.* for every horse enumerated in the missing tickets. This method of collecting the duty is found preferable to the system of farming to individuals the duties accruing in different districts. Penalties for neglecting to pay these duties are inflicted at the quarter-sessions. The total produce of the post-horse duty for the year 1839 was 237,452*l.* 7*s.* 5*d.*; for 1840 it was 224,405*l.* 15*s.* 11*d.*, showing a decrease of 13,046*l.* 11*s.* 6*d.*

The great superiority of English over foreign posting is a very strong evidence that the system of open competition in this trade is preferable to a government monopoly and control. The establishment of posting by governments no doubt arose originally from the supposition that it would not be generally undertaken by individuals: it has since been carried on by such governments principally for the purpose of raising revenue. We do not believe that good posting can be provided by governments; we are sure that under such circumstances it cannot be as good as public competition would secure. Where posting is a government monopoly, a minimum speed must be fixed for the protection of the public; this speed is usually uniform throughout a whole country, and is not greater in any part of such country than can be attained where circumstances are disadvantageous. It is the interest of the postmaster, who provides the horses, that this speed should not be exceeded, and if the postilion drive very slowly, the traveller has but two remedies; one, to complain to the authorities, which can only be done when the regulation pace is not attained; the other, to bribe the postilion. The latter system has become of such frequent use in most European countries, that bribes are, as it were, a customary payment, they are always expected by the postilion, and are of little service unless they exceed the customary rate of bribing. We think that the monopoly system does not render posting more general, but that in almost every district where it is now provided by governments, there is a sufficient demand to induce individuals to establish relays of horses on all important lines of communication. Under the free system post-horses are found throughout Ireland, where there is neither a rich resident population nor generally such other circumstances as attract travellers from other countries: there is no reason to suppose that there is a greater demand for posting in Ireland than on the continent of Europe generally. In the success of the voluntary system in Hungary, where circumstances must be considered far from favourable to its introduction, we have additional evidence that it might be substituted beneficially and without risk in most if not all the instances where government monopoly is retained. That revenue can be raised on posting, without the government acting as a postmaster, we have England for an example. There appears then to be no just ground for states continuing a monopoly which ensures a bad commodity without returning an adequate benefit.

POSTLETHWAYT, MALACHI, an eminent writer on commerce, is supposed to have been born about the year 1707; but no particulars relative to his origin or education, and very few relative to his after-life, appear to exist. In the introductory discourse to his work, entitled 'Great Britain's True System,' he says, pp. 62, 63, 'Nature having given me but a very tender and weak constitution, I have studiously declined and avoided, as much as I well could, every degree of the public life, as being inconsistent with and indeed destructive of that small share of health which I have several years enjoyed; and it will easily be believed that the studies I have been engaged in have not mended it. I therefore considered in what capacity I might prove useful to society; and accordingly betook myself to the studious life, experiencing that to be more consonant to my preservation than that of the active and public one.' In the previous paragraph he complains of the neglect with which his labours had been rewarded. 'Had the writer of these papers,' he observes, 'given no public or private testimony of his turn to studies that have proved useful to the state, it might be unreasonable, it might have been justly thought presumptive, in such an one to expect to make terms for his future intended services; but as the case is otherwise, he humbly hopes that some people will be candid and ingenuous enough to think that he has a right to be treated upon a footing something different from that of an upstart idle schemist or projector, who has never given proof of any talents that might deserve the public regard and attention.' This was published in 1757. The appeal does not appear to have been responded to either by the government or the public. He died September 13, 1767, suddenly, as he had often wished, and was buried in Old-street churchyard, the coffin, at his request, being filled with unslacked lime.

His other works are:—1, 'Considerations on the Revival of the Royal British Assiento between His Catholic Majesty and the Hon. the S. Sea Company,' 8vo., Lond., 1749; 2, 'The Merchants' Public Counting-house,' 4to., Lond., 1750; 3, 'The Universal Dictionary of Trade and Commerce, translated from the French of Savory, with additions,' &c. 2 vols. fol., Lond., 1751-56, last edition 1774; 4, 'A short State of the Progress of the French Trade and Navigation,' 8vo., Lond., 1756; 5, 'Britain's Commercial Interest explained and improved,' 3 vols. 8vo., Lond., 1757; 6, 'The Importance of the African Expedition considered,' 8vo., Lond., 1758; 7, 'The History of the Public Revenue, from the Revolution in 1688, to Christmas, 1753,' fol., Lond., 1759. This last is by James Postlethwayt, probably the brother of Malachi, though it is attributed to the latter by Watt in his 'Bibliotheca Britannica.'

(An article on 'Political Arithmetic,' in Sir Egerton Bridges's *Censura Literaria*, Lond., 1805, 8vo., vol. i., p. 59, &c.; *Gentleman's Magazine*, vol. 37, p. 479.)

POSTULATE (*postulatum*, *αἴτημα*), a thing required to be granted, or the use of which in reasoning is *demanded.* The distinction between a postulate and an axiom lies in this—that the latter is admitted to be self-evident; while the former may be agreed upon between two reasoners and admitted by both, but not as a proposition which it would be impossible to deny. We have [AXIOM] given our reasons for supposing that Euclid made this distinction, and that several of those propositions which are now written among the axioms were originally postulates. The distinction above made is really necessary; for example, writers on the evidences of Christianity assume the existence and attributes of the Creator as a postulate: they take them for granted. A person who is in the habit of not distinguishing these senses to which the words postulate and axiom have been affixed above, might say they assume the existence and attributes above mentioned as axioms, by which another person might understand things necessarily indisputable; while the writers themselves only mean by the assumption, that what they take for granted has been previously proved by writers on natural theology. The confusion which prevails as to the use of the word axiom would be lessened by the introduction and proper use of the word postulate, which is our reason for adding these few words to what has been said under AXIOM.

PO'STUMUS, a native of Gaul, distinguished himself in the Roman service, and was appointed by Valerianus governor of the Gauls. Under the weak reign of Gallienus he was saluted emperor by the troops in that part of the empire. Postumus ruled Gaul for ten years with great ability and moderation, says Eutropius: he repulsed the Germans, who had invaded the country, and restored peace, but he was at last killed in a mutiny of the soldiers headed by one Lollianus, because he would not allow them to plunder Moguntiacum (Mainz), which had revolted against him. He was succeeded in the command of Gaul by Victorinus, who was killed also two years after. (Eutropius; Trebellius Pollio, *Triginta Tyranni*, in 'Historia Augusta.')

Coin of Postumus.

British Museum. Actual size.

PO'SYDON, a genus of crustaceans, established by Fabricius, which M. Desmarest thinks should be placed near to *Albunea.*

POT-METAL, an alloy of lead and copper used for the purpose expressed by its name.

POTADO'MA, Mr. Swainson's name for a subgenus of fluviatile shells, genus *Melania*, subfamily *Melanianæ*, family *Turbidæ*. Mr. Swainson defines the form as having the general characters of *Melania*, but the outer lip hardly dilated, and the top of the inner lip internally thickened. He adds his suspicions that the true distinction of this second type of *Melania* will rest on the deciduous nature of the spire.

PO'TAMIS, a genus of fresh-water shells resembling *Cerithium* in the aperture, but differing from that genus by the possession of a thick horny epidermis. Mr. G. B. Sowerby, jun. thinks that it should be placed near *Melania* (*Manual.*)

Mr. Swainson makes *Potomis*, Brong. (*Potamis*), the first genus of his subfamily *Cerithinæ*, with the following character:—

Fluviatile, covered with a brown epidemis; whorls coronated and armed with spines; aperture almost entire, the notch being slightly developed; top of the outer lip with an obsolete sinus. Example, *Potamis muricata*.

Pirena immediately follows this genus in Mr. Swainson's arrangement.

PO'TAMO. [ECLECTICS.]

POTAMO'BIA, Dr. Leach's name for a genus of crustaceans allied to *Thelphusa.*

POTAMOMY'A, a genus of fresh-water shells bearing a resemblance to *Corbula*, and, in the opinion of Mr. G. B. Sowerby, jun., probably belonging to the *Myariæ*.

PO'TAMON, Savigny's name for a genus of crustaceans allied to *Thelphusa.*

POTAMO'PHILA, Sowerby's name for a genus of fluviatile conchifers.

Generic Character. — Shell thick, equivalve, inequilateral, trigonal, covered with a greenish brown, smooth, horny epidermis; hinge thickened, broad, with one central notched cardinal tooth in one valve, and two in the other, lateral teeth indistinct; ligament large, supported on prominent fulcra; muscular impressions two in each valve, suborbicular. (Sowerby.)

This is the *Venus subviridis* of some authors, *Galathæa* of Lamarck, previously used by him to designate a genus of crustaceans, and *Megadesma* of Bowdich, which last name Mr. G. B. Sowerby, jun. considers to have the right of priority. (*Manual.*)

Mr. Swainson adopts Bowdich's name, and places the genus under the subfamily *Cyclinæ*, family *Tellinidæ*.

POTAMO'PHILUS, Latreille's name for a genus of crustaceans allied to *Thelphusa*, if not identical with it. Indeed M. Desmarest thinks that *Potamon* and *Potamobia* differ but little, if at all, from *Thelphusa*.

POTASH. [POTASSIUM.]

POTA'SSIUM, a metal, the base of the alkali potash, in which it exists combined with oxygen. It was discovered by Sir H. Davy in the year 1807. He obtained it by subjecting caustic potash (hydrate of potash), slightly moistened to increase the conducting power, to the opposite poles of a powerful voltaic battery: by the decomposing agency of the electricity, he found that the oxygen both of the water and the potash was elicited at the positive pole, while the hydrogen of the water and the potassium of the potash appeared at the negative pole.

This process yields however very small quantities of potassium; and Gay-Lussac and Thénard shortly afterwards invented an apparatus by which a much more abundant supply was procured. For the details of this method we refer to the first volume of the 'Recherches Physico-Chemiques' of the chemists mentioned. The process consists essentially in bringing fused hydrate of potash into contact with iron turnings heated in a gun-barrel; at this high temperature the iron not only decomposes the water and combines with its oxygen, but it takes oxygen also from the potash, and the potassium set at liberty sublimes, and is collected in a cool part of the apparatus. Various improvements have since been made, and especially by MM. Brunner and Wöhler, the former of whom procured the metal by heating potash with iron and charcoal, and the latter by means of charcoal alone: in this case the accompanying products are chiefly either carbonic acid or oxide of carbon, or a mixture of these gases.

The properties of potassium are the following:—in colour and lustre it strongly resembles mercury; it is solid at the usual temperature of the air; at 50° it is soft and malleable, and yields like wax to moderate pressure, and at 32° it becomes brittle; at 70° it is somewhat fluid, but not perfectly so till the temperature reaches 150°; if heated to low redness, out of the contact of the air, it sublimes, and condenses on cooling, unchanged. Its texture when brittle is crystalline. Its specific gravity at 60° is 0·865; it is opaque, and a good conductor of heat and electricity.

The most remarkable chemical property of potassium is its great affinity for oxygen, which at common temperatures exceeds that of any other body for this elementary substance. It tarnishes rapidly and visibly by mere exposure to the air, and the more rapidly as the air contains moisture, which it decomposes, and by combining with its oxygen becomes oxide of potassium, or potash.

On account indeed of its powerful affinity for oxygen, it must be kept either in small glass tubes hermetically sealed, or in a fluid, such as naphtha, which contains no oxygen; when heated in the air it takes fire, burns with a purple flame, the evolution of much heat, and is converted either into potash or peroxide of potash, or a mixture of them. It takes the oxygen from any mixture of gases containing it, and indeed from almost every substance with which that element happens to be combined, so that when thrown upon water, it decomposes it with violent ignition, and the hydrogen of the decomposed water, combining with a little potassium, rapid combustion takes place, the principal products of it being water and oxide of potassium, or potash, which remains in solution. When, on the other hand, the potassium is put under an inverted tube containing water, no combustion takes place, if no air be admitted, and the results are hydrogen gas and potash.

All the elementary gaseous bodies unite with potassium, forming compounds of the highest importance and utility in many respects. We shall first describe the compounds of

Oxygen and Potassium: these form two compounds, protoxide and peroxide of potassium; the first has been known and extensively used from time immemorial, and is the substance formerly called the vegetable alkali, or potash, or more correctly hydrate of potash, and is now frequently called potassa; the peroxide has been known only since the discovery of potassium. Pure or anhydrous potash is obtained by the slow oxidation of potassium in dry air or dry oxygen gas; for if water be present, then the hydrate is formed. Its properties are that it is white, solid, extremely caustic, and readily attracts moisture and carbonic acid from the air; it fuses when heated, but bears a high temperature without being volatilized or decomposed. It combines readily with water, much heat being evolved during the combination, and its affinity for acids is extremely powerful; the aqueous solution possesses the properties termed alkaline in a high degree, such as reddening vegetable yellow colours, and restoring the blue colour of vegetables which has been reddened by an acid; it is the basis of all the oxisalts of potassium.

Potash, or protoxide of potassium, is composed of

One equivalent of oxygen . .	8
One equivalent of potassium . .	40
Equivalent .	48

This substance exists in some minerals, but in the largest quantity in Felspar [FELSPAR], of which it constitutes on an average at least ten per cent., existing in it in the state of silicate or combined with silica. Potash, as is well known, is extensively employed in the chemical arts and also in medicine, and for these purposes it is obtained by the incineration of wood, the ashes of which yield a considerable portion of this alkali. What is known in commerce by the name of potash is principally hydrate of potash, but mixed with some carbonate of potash and impurities; while the pearl-ash of commerce is principally carbonate of potash: they are both very largely imported, and chiefly from North America.

Hydrate of Potash is formed whenever an aqueous solution of potash is evaporated to dryness. If, for example, we throw a piece of potassium on water, and examine the solution after the combustion is over, it is found to contain potash; and if this solution be evaporated to dryness, the residue is not absolute potash, as was once supposed to be the case, but is a chemical compound of water and potash, from which no degree of heat is able to expel the water, but they may be volatilized in combination at a very high temperature. The usual method of obtaining hydrate of potash is to treat an aqueous solution of carbonate of potash (pearlash) with lime; this takes the carbonic acid, carbonate of lime is formed, and remains insoluble, while the potash dissolves, and the solution being evaporated, hydrate of potash, frequently called merely potash, is left.

The properties of hydrate of potash are, that it is white, hard and brittle, extremely caustic, very deliquescent, and very soluble both in water and in alcohol; by evaporating the aqueous solution, crystals are obtained containing much water. During solution in water a considerable degree of heat is evolved: the solution is colourless, and though inodorous, has a strong caustic disagreeable taste; it destroys the cuticle, and acts strongly on vegetable yellows; by acids, for which the alkali has great affinity, it is converted into various salts of great importance in science, medicine, and the arts. Potash is largely employed in glass-making, more especially flint-glass, in making soft-soap, and in the processes of calico-printing and many other chemical arts, and as a caustic in surgery.

Hydrate of potash is composed of—

One equivalent of water . .	9
One equivalent of potash . .	48
Equivalent . .	57

Peroxide of Potassium may be obtained by burning the metal in dry oxygen gas; an orange-coloured substance results, which is the peroxide in question. It is also procured when oxygen gas is passed over red-hot potash, and in small quantity when the hydrate is heated to redness in the air. This substance is not applied to any purpose whatever, and when merely put into water it is decomposed into oxygen gas, which escapes in small bubbles, and protoxide of potassium, or potash, which remains in solution: on account of this extreme facility of decomposition, it does not combine with any acids to form salts.

Peroxide of potassium consists of—

Three equivalents of oxygen	24
One equivalent of potassium	40
Equivalent	64

Azote and Potassium do not combine.

Hydrogen and Potassium form two compounds, but the composition of neither of them is known. When hydrate of potash is decomposed by iron at a white heat, a gaseous hydruret of potassium is procured, which burns spontaneously in oxygen gas or the air which contains it; the same compound is probably also produced when water is decomposed by the action of potassium upon it. When this gas is allowed to remain over mercury, the greater part and probably the whole of the potassium is deposited in a few hours. When potassium is heated in hydrogen gas, a solid grey hydruret of potassium is formed, which does not burn spontaneously like the gaseous compound in oxygen gas, but is readily decomposed by heat or the addition of water.

Chlorine and Potassium unite to form only one compound; its present name is chloride of potassium, but it was formerly called the febrifuge salt of Sylvius, and afterwards muriate of potash. It may be obtained in several ways: when the metal is put into the gas, spontaneous combustion ensues, and a white inodorous compound is obtained, which has a taste greatly resembling that of common salt; when also potassium is heated in hydrochloric-acid gas, hydrogen gas is evolved, and the chloride of the metal formed; and lastly, when potash is dissolved in a solution of hydrochloric acid, and the solution is evaporated, cubic crystals of this salt are formed, which are colourless, inodorous, saline, and rather bitter to the taste; it is soluble in about three times its weight of water at 60°, and more so in hot water; in alcohol it is insoluble. It was formerly employed in medicine, but is not at present; it is sometimes produced in chemical operations as a residue, and is then used in alum-making. It yields by analysis—

One equivalent of chlorine	36
One equivalent of potassium	40
Equivalent	76

Fluorine and Potassium combine to form the fluoride. This salt is procured by mixing the aqueous solutions of hydrofluoric acid and potash; by their mutual decomposition a solution of fluoride of potassium results, which, when the solution is properly evaporated, yields cubic crystals; they are colourless, deliquescent, have a sharp saline taste, and dissolve readily in water.

This salt is composed of—

One equivalent of fluorine	18
One equivalent of potassium	40
Equivalent	58

Bromine and Potassium combine by direct action, or by the action of the bromine upon a solution of potash; in this last method a mixture of bromide of potassium and bromate of potash is procured, which, by evaporation to dryness, and subjecting it to a red heat, is totally converted into bromide. It is most commonly prepared by first forming a bromide of iron, and decomposing that salt with potash. These yield by double decomposition the bromide in question, which remains in solution, and hydrate of iron, which is precipitated.

By evaporating the solution, cubic crystals of bromide of potassium are procured; which are colourless and inodorous, have a very penetrating taste, are very soluble in water, and most so when it is hot. By heat this salt suffers igneous fusion, but is not decomposed. It is decomposed by chlorine, which evolves bromine; this salt is sometimes employed in medicine, and is constituted of—

One equivalent of bromine	78
One equivalent of potassium	40
Equivalent	118

Carbon and Potassium have been supposed to combine, but it is questionable, and the compound has not, at any rate, been procured in a pure state.

Sulphur and Potassium probably combine to form five different compounds; the union takes place readily when these elements are heated together, and the nature of the compounds depends upon the relative quantities of the ingredients employed.

We shall describe only the protosulphuret, or that consisting of—

One equivalent of sulphur	16
One equivalent of potassium	40
Equivalent	56

This may be obtained by decomposing sulphate of potash at a red heat by hydrogen or charcoal. Its properties are that it has a red colour, has a disagreeable alkaline and sulphurous taste, is alkaline to test-papers, deliquesces on exposure to the air, and is soluble both in water and in alcohol. Most acids decompose it, and during their action much hydrosulphuric acid gas is evolved; it is also decomposed when added to solutions of the different metals in acids, the colour of the precipitated sulphuret depending upon the nature of the metal. This substance, mixed with some sulphate of potash, is occasionally used in medicine in cutaneous disorders.

Phosphorus and Potassium and *Selenium and Potassium* form compounds, but they are not of importance.

Iodine and Potassium may be made to combine, so as to form the iodide of the metal, by dissolving the iodine in a solution of the alkali; but the residue obtained by evaporation requires heating to convert the iodate of potash, which is also formed, into iodide of potassium. It is usually procured by decomposing a solution of iodide of iron by means of potash; the solution separated from the precipitated hydrate of iron is colourless, and by evaporation yields colourless and cubic crystals. The properties of this salt are, that it has a penetrating taste; it is very soluble in water, but absolute alcohol dissolves it sparingly; at a red heat it fuses, and at a very high temperature it is volatilized without suffering decomposition.

It is used in medicine to a very considerable extent, and is composed of—

One equivalent of iodine	126
One equivalent of potassium	40
Equivalent	166

Cyanogen and Potassium combine. When carbonate of potash is heated, with twice its weight of dried blood or other animal matter, to redness, and the residue, when cold, is washed with water, a mixture of carbonate of potash and cyanide of potassium is dissolved, which, when precipitated with acetate of lime, filtered, and mixed with alcohol, yields a precipitate, which is cyanide of potassium.

This salt is very soluble in water, and when once procured in the solid state, it should be kept from the contact of air and water. It may be fused by heat without decomposing; its taste is pungent and alkaline, accompanied with a flavour of hydrocyanic acid, and the smell of this acid is perceptible when it is exposed to the air, the carbonic acid of which causes its expulsion; by the action of acids it is resolved into hydrocyanic acid, which is expelled, and potash, which unites with the acid. It is sometimes employed in the preparation of hydrocyanic acid.

It is composed of—

One equivalent of cyanogen	26
One equivalent of potassium	40
Equivalent	66

Cyanide of Potassium combines with iron to form a well-known and extensively employed salt, the

Ferrocyanide of Potassium, sometimes called *Prussiate of Potash*, or the *triple Prussiate of Potash*. This salt is obtained by indirect chemical action. When animal matter, as hoofs or horns or blood, is heated in an iron vessel with potash, a compound is obtained, which consists principally of cyanogen, iron, and potassium. This is very soluble in water, and the solution by evaporation yields large crystals of a fine yellow colour, and the primary form appears to be a cube. This salt is inodorous; its taste is rather saline; water at 60° dissolves about one-third, and at 212° its own weight of this salt; it is insoluble in alcohol; when moderately heated it loses about 13 per cent. of water, and becomes colourless. When heated to redness with access of air, it suffers partial decomposition: the residue when put into water leaves oxide of iron, and cyanide of potassium is formed; and this is the best method of obtaining this salt. When the heat is long continued, the salt is entirely decomposed, ammonia is formed and evolved, and a mixture of carbonate of potash and peroxide of iron remains.

When this salt is added to a solution of a persalt of iron, that beautiful pigment Prussian blue is formed, and it precipitates most metals from their solutions in acids. This salt is also and very largely used in preparing hydrocyanic acid, which it readily yields when heated in a retort with sulphuric acid.

It is composed of—

One equivalent of cyanide of iron	54
Two equivalents of cyanide of potassium	132
Three equivalents of water . .	27
Equivalent . .	213

Salts of Oxide of Potassium, or Oxisalts of Potassium.

Potash Salts.—Potash has powerful affinity for most acids: the salts which they form are never prepared, as many metallic salts are, from the direct action of the acid and metal, and but seldom indeed from the immediate combination of the alkaline oxide, or potash, with acids. Some of the most important salts are found native, and others are very commonly the result of chemical operations performed with the intention of preparing other products at the same time.

The first salt of potash which we shall mention is one of the highest importance: it is the

Nitrate of Potash, Nitre, or Saltpetre.—It is quite true that this salt may be artificially formed by adding either the metal or its oxide, potash, to nitric acid; but it is never so obtained, being in some countries formed by the putrefaction of animal matters, in others it is a natural product, and to a very great extent, and as such is largely imported from the East Indies under the name of rough nitre, where it is obtained by the lixiviation of certain soils: in Germany and France it is artificially produced in what are termed nitre-beds. M. Thénard has given a detailed account of the French process, in his 'Traité de Chimie.'

The properties of nitrate of potash are, that it is colourless, inodorous, has a cooling sharp saline taste, and is readily soluble both in cold and in hot water: from the latter prismatic crystals separate on cooling, the primary form of which is a right rhombic prism; but they are usually six-sided prisms, with dihedral summits: when obtained from a large quantity of solution, the crystals are of very considerable size. The crystals contain no combined water, but it is commonly mechanically lodged between their laminæ. At about 616° of Fahr. nitre fuses, and at a high temperature it suffers decomposition; and the residue, according to the degree or continuation of the heat, is either hyponitrite of potash, potash, or a mixture of potash and peroxide of potassium. Nitre occasions much cold during its rapid solution in water, so that an ounce of it is capable of reducing five times its weight of water fifteen degrees. Nitre possesses powerful antiseptic properties. It is largely employed in the manufacture of gunpowder and of nitric acid, and also in numerous processes in the chemical arts and manufactures.

It consists of—

One equivalent of nitric acid . .	54
One equivalent of potash . .	48
Equivalent . .	102

Chlorate of Potash.—This salt is entirely an artificial one. It is prepared by passing chlorine gas into a solution of potash: during their mutual action there are formed chlorate of potash and chloride of potassium; and the chlorate, being the less soluble of the two, crystallizes first. This salt is colourless, inodorous, and has a cooling austere taste. The primary form of the crystal is an oblique rhombic prism. The crystal contains no water. It is soluble in eighteen parts of cold and two and a half parts of boiling water. When triturated, it appears phosphorescent; and if heated to redness, it fuses, gives out nearly 40 per cent. of very pure oxygen gas, derived both from the decomposition of the acid and the potash, and mere chloride of potassium remains. When triturated with certain inflammable bodies, as sulphur and phosphorus, combustion or explosion, or both, are produced: these effects are produced by the oxygen of the decomposed chloric acid.

This salt is also decomposed by sulphuric acid, giving out oxide of chlorine. [Chlorine.] In 1788 an attempt was made in France to use this salt, instead of nitrate of potash, in the manufacture of gunpowder; but when the mixture was triturated, so violent an explosion occurred as to kill several people.

It is constituted of—

One equivalent of chloric acid . .	76
One equivalent of potash . . .	48
Equivalent . .	124

Chlorate of potash is employed in chemical investigations on account of the purity of the oxygen gas which it yields; it is also employed in the manufacture of matches which are fired by means of friction. When this salt is mixed with sugar, or metallic arsenic, or antimony, a drop of sulphuric acid will set the whole in rapid combustion.

Carbonate of Potash.—This salt is known in its impure state by the name of *pearlash:* it is rendered pure by solution, filtration, and evaporation to dryness, it being a salt which does not readily crystallize.

Pearlash, as already mentioned, is procured by the incineration of wood: when treated with a small quantity of water, but little except the pure carbonate of potash is dissolved. The solution, when evaporated till it becomes a granular solid, has the following properties:—it is colourless and inodorous, its taste is strong and disagreeable, it does not readily crystallize, and is never kept in crystals; it is deliquescent, attracting in a short time enough water from the atmosphere to become fluid: water dissolves rather more than equal weight of this salt; it is insoluble in alcohol; the aqueous solution has the alkaline property of turning vegetable yellow colours reddish-brown, and hence it was formerly called subcarbonate of potash; but it is in fact a neutral carbonate, consisting of—

One equivalent of carbonic acid . .	22
One equivalent of potash . . .	48
Equivalent . .	70

But, as usually prepared, it is a sesquihydrate, and contains about 16 per cent. of water, which it loses by exposure to a red heat, and becomes anhydrous. This salt may be artificially prepared by passing carbonic acid gas into a solution of potash, or by deflagrating a mixture of charcoal and nitre: in this case the charcoal is converted into carbonic acid at the expense of the oxygen of the decomposed nitric acid.

This salt is largely employed in the arts, and also in medicine; it is decomposed by most acids, with effervescence of carbonic acid gas: it is also decomposed by lime and by barytes, which separate its carbonic acid, but without effervescence: no degree of heat is sufficient to expel its carbonic acid.

Bicarbonate of Potash.—When carbonic acid gas is passed into a solution of carbonate of potash, the salt combines with an equivalent of carbonic acid, and becomes a bicarbonate. This salt is inodorous, colourless, and crystalline; has scarcely any alkaline taste, and acts feebly upon turmeric paper: the primary form is a right oblique-angled prism. It is not altered by exposure to the air, requires four times its weight of cold water for solution, and by boiling water it is partially decomposed, with the evolution of carbonic acid gas: in alcohol it is insoluble. When exposed to a red heat, it loses half its carbonic acid, and reverts to the state of a neutral carbonate.

Bicarbonate of potash consists of—

Two equivalents of carbonic acid . .	44
One equivalent of potash . . .	48
One equivalent of water . . .	9
Equivalent . .	101

It is largely employed in medicine and in chemical investigations.

Sulphate of Potash is an artificial salt: it is seldom prepared by the direct combination of its constituents, but is readily obtained by the addition of the acid either to potash or the carbonate. It is formed largely in the preparation of sulphuric acid and also of nitric acid by adding sulphuric acid to nitrate of potash: by dissolving the residue in water, and saturating the solution with potash, the sulphate is obtained, which possesses the following properties:—it is colourless, inodorous, bitter, and rather hard; water at 60° dissolves only one-sixteenth of its weight, but boiling water a much larger quantity; it is insoluble in alcohol, and suffers no change by exposure to the air: when subjected to a red heat, it decrepitates, losing but little weight, for it contains no water of crystallization. The primary form of the crystal is a right rhombic prism, but it has often the appearance of a dodecahedron, consisting of two six-sided pyramids applied base to base.

It yields by analysis—

One equivalent of sulphuric acid	40
One equivalent of potash	48
Equivalent	88

It is now little employed in medicine; but it is used in the manufacture of alum, and as a residue is often decomposed and converted into carbonate of potash.

Bisulphate of Potash is produced during some of the processes employed for obtaining nitric acid from nitre, as when two equivalents of the acid are used with one equivalent of the salt: the properties of this salt are, that it is colourless and inodorous, but extremely sour and bitter; it is very soluble in water; the solution reddens vegetable blues very strongly, and decomposes carbonates with effervescence. When exposed to a red heat, it loses all the water of crystallization and half the acid, and becomes neutral sulphate of potash.

The primary form of the crystal is a right rhombic prism, which is frequently very flat.

It contains—

Two equivalents of sulphuric acid	80
One equivalent of potash	48
Two equivalents of water	18
Equivalent	146

This salt sometimes crystallizes with only one equivalent of water, and it is then in fine filamentous crystals.

It is a little, and but little, employed in medicine; the rough salt is employed in some chemical manufactures under the name of *sal enixum.*

Sesquisulphate of Potash has been occasionally formed: it is in fine slender crystals.

There are two salts of potash, consisting of the alkali combined with vegetable acids, which it will be proper to mention, and with which we shall close this account of the salts of potash, premising that there are several other important compounds for an account of which we must refer to chemical authorities.

Bitartrate of Potash, Cream of Tartar, or *Tartar.*—This salt is obtained by the purification of argol, which is the name of the impure salt deposited from wine. Bitartrate of potash is colourless, rather hard, inodorous, and has a sour taste; when dissolved in water it reddens litmus paper; it requires sixty parts of cold and fifteen parts of boiling water for solution; by long exposure to the air the dissolved salt is decomposed and converted into carbonate of potash, and the same effect is immediately produced by a red heat. The residue, put into water, leaves charcoal, and the carbonate of potash is dissolved.

The primary form of the crystal of this salt is a right rhombic prism.

It consists of—

Two equivalents of tartaric acid	132
One equivalent of potash	48
One equivalent of water	9
Equivalent	189

It is very largely employed in the preparation of tartaric acid, in medicine, and some chemical arts. When an equivalent of potash is added to this salt, it becomes *neutral tartrate of potash:* this salt is used in medicine, and being much more soluble in water than the bitartrate, was formerly called *soluble tartar.*

Oxalic Acid forms three different compounds with potash, the oxalate, quadroxalate, and binoxalate; this last is a natural product obtained from sorrel, and is commonly known by the name of salt of sorrel. It is a colourless crystalline salt, has a sour bitterish taste, and is soluble in about ten parts of water.

It is composed of—

Two equivalents of oxalic acid	72
One equivalent of potash	48
Equivalent	120

General properties of the Salts of Potash.—These are stated by Mr. Brande to be nearly as follows:—They are soluble in water, and afford no precipitates with the alkalis or their carbonates. They produce a precipitate in the solution of chloride of platina. They are not changed by ferrocyanide of potassium or hydrosulphuric acid. Added to sulphate of alumina, they occasion it to crystallize, the crystals being common alum: a strong solution of tartaric acid added to a strong solution of potash, causes no precipitation till the point of neutralization is exceeded; but then a crystalline precipitate of bitartrate of potash is formed, on account of the slight solubility of this salt, which redissolves when excess of potash is added to it. Tartaric acid also occasions precipitation in solutions of the neutral salts of potash, as the nitrate, sulphate, and chlorate.

POTASSIUM, or POTASSA, *Medical Properties of.* The preparations of potash which are used in medicine are very numerous; but they may be reduced and spoken of under a very few heads:—first, those which are employed from their causticity to produce counter-irritation, or to open abscesses: these are hydrate of potash (potassa fusa) and potash with lime (potassa cum calce), which have been already treated of. [ESCHAROTICS.] Second, those which are employed to counteract acidity, viz. liquor potassæ, carbonate and bicarbonate of potash, the causticity of which last two is diminished in proportion to the increase of the carbonic acid combined with the alkali. Thirdly, those which possess a purgative property, such as the sulphate and bisulphate of potash, the tartrate and bitartrate. Fourthly, those possessed of a diuretic property, such as the acetate, and, when in small doses, the nitrate and chlorate of potash. Besides these, there are the sulphuret of potash, the bromide of potassium, and iodide of potassium, which possess special and characteristic qualities, which prevent their being classed with any of the preceding.

The various uses of which these numerous preparations are susceptible can only be explained in medical treatises: all that is proper here is to caution individuals against the employment of those which counteract acidity. These are extensively had recourse to, either in a simple state or as ingredients in effervescing mixtures, for the cooling effect they produce, or designedly to remove superfluous acid in the stomach. Where much debility exists, and more particularly if the phosphatic diathesis, or disposition to the deposit of the phosphates from the urine, be present, a single dose of such articles may do much injury, and their frequent or prolonged use creates a worse condition than that which they were intended to remedy. An intelligent medical attendant can alone decide on their propriety. 'If I were required,' says Dr. Prout, 'to name the medicine calculated to do the most mischief, I should name the common saline draught formed of potash or soda and some vegetable acid.' (*Treatise on Diseases of the Urinary Organs,* 2nd edition, p. 145.) [CARBONIC ACID.]

The property assigned to bromide of potassium, of removing enlargements of the spleen, is by no means clearly proved. The powers of iodide of potassium have been noticed under IODINE, and those of the sulphuret of potassium are treated of under SULPHUR. In case of poisoning by liquor potassæ or the carbonates, vegetable acids or oils should be instantly administered.

POTATO (*Solanum tuberosum,* Lin.). The circumstances which led to the introduction of this valuable vegetable into the system of British husbandry may be thus succinctly stated:—

Queen Elizabeth, in 1584, granted a patent 'for discovering and planting new countries not possessed by Christians;' and under this sanction some ships, principally equipped by Sir Walter Raleigh, sailed with him to America. Thomas Harriott (afterwards known as a mathematician), who accompanied the adventurous squadron, transmitted to England the description of a plant called *Openawk* by the natives of that part of North Amerca, which the courtier-like gallantry of Raleigh had named Virginia.

Harriott described the *Openawk* as having the roots round, and 'hanging together as if fixed on ropes, and good for food, either boiled or roasted.' Gerarde, in his 'Herbal,' a few years subsequently, distinguished the plant by a plate; and not only confirmed the assertion that it was an indigenous production of Virginia, whence he himself had obtained it, but supplied some curious details of its qualities, and of the various modes in which it may be dressed for the table. He especially recommended it as the basis of 'delicate conserves and restorative sweetmeats,' with the assurance that its flatulent effects may be infallibly corrected by having the roots 'eaten sopped in wine;' adding, 'to give them the greater grace in eating, that they should be boiled with prunes.'

The honour of first cultivating the potato in Ireland, where it has so long constituted the principal food of the peasantry, has been attributed to the grandfather of Sir Robert Southwell, president of the Royal Society of London, towards the close of the seventeenth century. Sir Robert's statement was to the effect that his ancestor had obtained some roots from Sir Walter Raleigh. The well-known story of Raleigh's having first planted the potato in his garden at Youghal, and of the disappointment of the gardener in autumn on tasting the apples of the 'fine American fruit,' and of his subsequent discovery of the tubers, when he was desired by his master to throw out 'the useless weeds,' is probably authentic also.

But the potato had been known in Spain and Portugal at an earlier period, and it is from the latter country that we most directly derive the name by which we know it: this is easily shown. Although the natives of North America called our plant openawk, those of the south, more particularly the inhabitants of the mountains of Quito, called it papas, which the Spaniards corrupted into battata: this again their neighbours in Portugal softened into ba-ta-ta (da terra), to which po-ta-to is a very close approximation.

The potato was cultivated in Ireland long before its introduction into Lancashire, which was owing to a shipwreck, it is said, at North Meols, at the mouth of the Ribble, where the mode of propagation still maintains pre-eminence, and whence the culture of this important plant has gradually spread through every portion of Great Britain.

It was not however until after a considerable time that it became palatable, productive, and farinaceous, or admitted into the course of field husbandry. It was limited to the garden for at least a century and a half after it was first planted at Youghal, and it was not until 1732 cultivated as a field crop in Scotland. It appears (from the 'General Report of Scotland') that in the year 1725-6 the few potato plants then existing in gardens about Edinburgh were left in the same spot of ground from year to year, as recommended by Evelyn: a few tubers were perhaps removed for use in the autumn, and the parent plants were well covered with litter, to save them from the winter's frost.

A strange objection to potatoes was urged by the Puritans, who denied the lawfulness of eating them, because they are not mentioned in the Bible; but whether we view this vegetable with reference to its adaptation to every soil and almost every climate, or as a great source of food and nutritive properties, it must be ranked among the best gifts of Providence.

Though the plant may be propagated both by its seed and tubers, practical management has confined the cultivation to the latter mode, except for the purpose of raising new varieties or renewing old ones. Those who are curious about varieties (which are now innumerable), can almost indefinitely pursue their object; for the seed of a species, the red apple for example, will sport, and this too without hybridising (that is, without the admixture of its seed with that of any other species, the produce of which would be hybrids) into numberless varieties of form and colour—round, flat, oblong, red, pink, black, white, mixed, and purple, of every shade and colour. These, whether hybrids or not, are reproduced through successive seasons by the tubers alone, if they possess those qualities which render them desirable for continued cultivation, on account of peculiar adaptation to early or late seasons, size, predominance of farina, &c.[*]

This mode of propagation by tubers either improves those qualities or gradually develops objectionable properties. Some varieties are therefore permanently established, while the culture of others is either abandoned, or, if continued, it is known that those varieties revert in the course of a few generations to the nature of their parent kind, and therefore cease to constitute a variety.

In the vegetable kingdom, hybrid plants have not the power of propagation by seed; but they can be rendered reproductive by budding and grafting, or by means of cuttings, slips, and tubers, and an original stock comparatively worthless may be highly improved by such modes of multiplication. But when a farmer possesses two or three kinds of decided excellence, he will act wisely by not encumbering his stores with too many varieties, which always occasion trouble and confusion in the field management.

In order to obtain seed, properly so called, the apple, when perfectly ripe, should be dried, and then disengaged from its seed by rubbing with the hand. The seed should be preserved in a dry place, in paper or cloth bags, until the middle of March or beginning of April, when it may be sown in wooden boxes or earthen pans, with a covering of less than half an inch of well pulverised earth. The vessels ought then to be placed in hotbeds of mild heat, such as is suited to the raising of half-hardy annuals. The plants, when an inch high, should be pricked out into other vessels, and placed in a temperature somewhat lower than before, to inure them to the external air, to which they should be exposed after frosts have ceased. These plants should be put out in drills sixteen inches apart, and with the interval of six inches between the plants in the rows. They will produce tubers in the first year, and these may be planted in the following season in the ordinary way.

For very early crops, such as those which the ash-leaved and walnut-leaved kinds in particular yield, the most successful treatment was that practised by the late Mr. Knight, president of the London Horticultural Society, from the course of whose practice we give the following details of instruction:—Drills may be formed in a warm and sheltered situation (and in the direction of north and south) during any of the winter months, two feet apart, and seven or eight inches deep. Stable dung, half decomposed, should be laid in the drills and combined with the earth four inches downwards, and covered with some of the mould, which had been thrown out in forming the drills, by the rake, to within four inches of the surface. The sets uncut are then to be placed, with the crown eye uppermost, in the centre of the furrow, four inches from each other, and to be covered with only an inch of mould at first, and afterwards with an occasional quantity of sifted ashes, until the plants are so vigorous and advanced as to require the usual earthing, of which however very little is necessary. Mr. Knight used leaves as a lining at the sides of the drills in the early periods, to preserve as much warmth as possible, and better to guard against the effects of frost.

This management alone will be found successful, except perhaps in very tenacious clay soil, in which the rains of winter may lodge so near the fibres of the plants as to destroy them altogether; but destruction from this cause may easily be avoided by increasing the original depth of the furrows and loosening the bed of clay below with the spade to such a depth as will allow the water to descend from the surface, with a drain to carry it off altogether; or by laying below some absorbent matter, such as ashes, chalk, or calcareous gravel.

The germination of the sets may be accelerated by a little management previously to their being planted, by laying them on a floor, sprinkling them with water until they bud, and then covering them with finely-sifted mould. If this be done in December or early in January, the sets, with strong shoots, may be taken up in February (with as much earth as possible adhering to them), and carefully placed in the drills prepared as directed, and covered with well-rotted leaves or earth in the same way.

To market-gardeners it is a great object to raise the earliest potatoes, considering the high price which they obtain for them, though in their waxy state they are neither wholesome nor palatable. Next in early maturity to the ash-leaved and walnut-leaved are the early Manly and early Champion and Fox's seedling.

The best soil for potatoes generally is that which is altogether fresh from the state of ley, or which has not long been broken up: land which has been in grass for only two or three years is easily prepared for the principal crop. It should be as deeply ploughed as possible before winter, and early in March harrowed, and thoroughly cross-ploughed. After lying in this state for two or three weeks, it should again be well harrowed and very deeply ploughed twice, without bringing up any bad substratum, and it will then be fit for the reception of the crop.

The most approved modes of setting are as follows:—Drills should be formed in the well-pulverised field, with double boutings of the plough, in order to have the shoulders uniform, which is essential to the correctness of succeeding operations. The dung is then to be carted out, and divided by the carter with a drag-fork as his horse and cart move forwards (the horse walking in the centre of three drills while the wheels move in the other two), in such quantities as can be most conveniently shaken out into the drills by the labourers employed to spread it. In dry weather the carting does no injury, and this method is universal in Scotland. The other principal mode, more generally pursued in Ireland by some of the best cultivators of the potato, is to cart out the manure before the drills are formed, in rows seven or eight yards apart, and to supply the drills from the heaps as the plough advances in its work, reserving just as much as is supposed sufficient for the concluding drills, which are to be made in the sections of the field previously occupied by the rows of manure. By the latter treatment the manure may be laid over the sets—which cannot be done in the former case—and this will preserve them from being displaced or crushed by the feet of the horses during the process of covering the seed. But against this advantage—which is not inconsiderable—there is the inconvenience of calculating with precision and laying aside as the plough advances to draw the last drills—where the rows had stood—the precise complement of manure, and the difficulty to the ploughman of preserving the exact breadth in those drills.

---

[*] M Sargeret, a distinguished and accurate French experimentalist, referred to in the 'Dictionnaire d'Agriculture,' found that out of 300 varieties he had not one exactly like the original from which they were raised; and out of this great number he only found three worth perpetuating.

Some avoid any perplexities in those respects by ploughing in the manure thoroughly before drilling, and either dropping the set in every third furrow, or rolling the whole manured and ploughed surface, and then making drills. Our own experience is greatly in favour of this latter mode, when the fertilising matter is abundant and of the short description which freely combines with the soil and does not obstruct the plough in the subsequent drilling. The lazy-bed method is so generally condemned that any explanation of it here would be superfluous, yet in undrained bog-land, or under any circumstances in which a redundancy of wetness is probable in the autumn, as on low marshy lands, or stiff clay soils which have no sufficient inclination to carry off the water, and are likely to be saturated with moisture in winter from want of drainage, the lazy-bed system is by far the safest. The deep wide furrows at each side carry off the water, or at least remove it from the potato. Thousands of tons of potatoes in the last year (1839) were utterly lost in Ireland, being drilled in flat and tenacious lands, which would have escaped destruction from the continued rains of that season if drained by the furrow of the lazy-bed. Besides, where circumstances preclude the practicability of deep ploughing, the lazy-bed practice repeated for three years will completely spade-trench the entire land, and thus effect an important benefit not otherwise attainable by the humble tiller of the soil who has no teams for ploughing it effectually. Thus local or national modes, though apparently defective to the superficial observer, are sometimes founded upon sound principles, and though we feel disposed to exclude the minute details of what is only defensible under peculiar circumstances from an essay on potato culture under our modern system, we protest against the unqualified condemnation of a method which is still pursued throughout nearly one half of Ireland.

The sets (uncut, for reasons to be yet assigned) are next to be laid down, either under or over the manure, at the average distance of sixteen inches, by the setters, who move in a retrograde direction, and are provided with aprons to contain the sets. A sufficient number of men is in attendance to divide the manure evenly in the drills; the plough also is in the field in order that there may be the least possible exposure of the manure and sets to the sun or to parching wind, but the plough should cover the sets rather lightly in clay soil.

The roller is next used to lay an even surface to the brairding* plants and to facilitate the subsequent progress of the paring plough, which is to be set to work when the stems are six or seven inches high, and should move as close to the plants as is practicable without injuring their tender fibres. The weeders should then hoe the plants carefully, and immediately afterwards (for the influence of wind or hot air on the roots is pernicious) the scuffler or drill-harrow is to follow, in order to clean and level the intervals, before the earthing plough, with either double or single mouldboard, is introduced to apply fresh earth to the stems.

Such is the method of earthing universally pursued by the farmer in Ireland and Scotland, but in England the hand-hoe is principally used for destroying weeds, loosening the earth, and moulding the plants; for the two first of these operations the bean-hoe (which cuts about six inches deep) is used, and the turnip-hoe for drawing the earth to the stems. One man will hoe out the weeds and loosen the soil of half an acre per day, and the subsequent earthing of the same quantity is also executed by one man. This is far cheaper than horse-work, and it does no injury to any of the stems, and makes no waste land at the headriggs; and where the earth has been perfectly well prepared at the commencement, this manual husbandry is the best.

If this system be found most effectual in England, where the wages of a labourer are 2*s.* a day, it must be far more so in Ireland, where they are but half that amount, and where practice would soon give sufficient dexterity in the use of the hoe.

As to the distance between the drills, due regard must be had to the natural quality of the soil and the quantity and description of manure available, or in other words, to the probable luxuriance of foliage. Mr. Knight, aware of the necessity of allowing room in proportion to the vigour and height of the plants, has laid down an exact rule thus:—'the height of the stems being three feet, the rows ought to be four feet apart:' but for a general average, thirty inches is the best distance. As to excess of foliage, we are certain that it is not desirable, for the produce of tubers is not always in proportion to the degree of foliage; under high and rank stems there is often a very scanty crop, and Mr. Knight is justified by experience in his observation that 'the largest produce will be obtained from varieties of rather early habits and rather low stature, there being in very tall plants much time lost in conveying the nutriment from the soil to the leaves,' and consequently strong and upright stems, which do not fall down and shade the others, are those which are desirable.

Two more earthings are usually given, but it is questionable whether even one be necessary in soil of average depth, unless there be a very wide interval between the drills, and it is certain that much earthing in dry and shallow soil is injurious; for by withdrawing the earth from contiguity to the fibres which ramify and penetrate far in loose soil, and laying it on the head of the drill, and in the high ridgelet form, it is applied where it is useless for the nourishment of the tubers, and in a position that favours the rapid escape of moisture, which in such soil it ought to be an object to retain. In deep land, more particularly if it be of tenacious quality, the furrows at each side of the drill will be in general seasons most serviceable as drains, as well as for furnishing earth to support the stems, while the moisture will be sufficiently retained for the roots.

Experiments* have led to the inference that in soil of a loose porous quality there is probably a greater produce by not affording any (or a very slight) moulding, but by digging instead, between the rows; for deep and perfect pulverization, next to an adequate allowance of rich manure, is the main cause of a large produce. In proportion to the deficiency of manure will be the necessity for opening the soil beneath, to allow the fibres, which may be distinctly traced to a depth incredible to those who have not followed their ramifications, to extract all the nourishment which the subsoil may afford. If there be abundance of nutriment above, neither the necessity nor perhaps the inclination for penetrating deeply can exist, and in such cases the operation of earthing by the plough, as long as it can be introduced without injury to the stems, may be useful in many ways, but unquestionably by guarding them from the effects of storm in exposed, and from excessive wetness in low situations. Besides, in regulating this point, regard should always be had to the quality of the potato, for the tubers of some varieties have a tendency to push to the surface, while others tend into the earth, and therefore require a different treatment.

But in all cases the earth should be rendered as loose and friable as possible, by spade, hoe,† or plough, and where labour is easily commanded, the spade will be found to be the more efficacious implement in the first course of treatment after the plants are well up.

Some plant one or two sets in the centre of every square yard, but in such cases great and continued earthing, until each square presents the form of a pyramid, is contemplated; and if our preceding remarks be correct, this treatment is only applicable to deep and retentive soils. Great returns have no doubt been thus obtained, but by this mode there is the least possible incorporation of the manure with the soil.

In minute husbandry, such as that exemplified in labourers' allotments, which excludes the plough altogether, the ordinary and best practice is to lay the sets in rows, after a very deep winter digging, marked with a garden-line. The workman digs precisely as in a garden-plot for cabbages: he clears a little drill, lays the sets straight, puts a sufficiency of manure over them, and then covers from the next spit, which he digs with a spade or a three-pronged fork flattened at the ends, levelling and pulverising as he advances to the distance at which he again puts down his line and forms a new drill. Thus the entire piece is thoroughly loosened, the manure perfectly covered, and every facility given for the hand-hoeing in due course.

---

* A Scotch term, signifying 'shooting out.'

* See Martin Doyle's 'Cyclopædia of Practical Husbandry,' page 372.

† That kind called the bean-hoe, shaped like an adze.

The next stage of the potato is that in which it blossoms. It has been recommended to pluck off the flowers. Excessive blossoming is no doubt injurious, but experience has generally proved that the extra cost is hardly defrayed by the additional produce obtained. If the flowers are plucked off, they should be nipped in the early bud.

When the crop is fully ripe, which is indicated by the withering of the stalks, and when the land is free from stones, labourers, in the proportion of about twenty to one plough (half of these being usually men, and the remainder women or young persons), should be set to pull up the stalks, and carefully collect the tubers which may be attached to them, before the plough proceeds in its operation. When it is prepared for work, the men, with prongs flattened at the extremity, are placed at such distances from each other as will give them proper time to fork out the potatoes cleanly for the pickers, who are also stationed at exact distances with a basket between every pair, into which they gather the potatoes.

The common swing-plough may be employed in three ways:—First, in taking off a slice from each side of every drill, and leaving it to the workmen to open out the centre with their prongs; or in its third movement it may turn up this centre, under which the main body of the tubers lie, which is more expeditiously and easily done if the earth be in fit condition. Second, a double mould-board plough with a long sack, and divested of its coulter, may be drawn by two strong horses through the centre of the drills, and completely under the level of the tubers, so as to avoid injuring them, by which means the work-people will be kept exceedingly busy; and if the land be in good friable order, this is the most expeditious mode, and provided there is a perfect harrowing afterwards, the crop will be taken out with sufficient cleanliness. Third, the crop may be taken up by prongs or long narrow spades without the plough. In wet weather this more tedious but far safer method is frequently adopted, and if the drills be short and the headriggs under crop also, it is the most desirable, effectual, and economical mode. In removing the produce in this manner, it is obvious that the number of gatherers should be much less in proportion to the men, than under the other circumstances. The headriggs should evidently be the first parts of the field cleared, to make a free space for the ploughs in the boutings and for the carts.

One horse will answer for three carts if the distance of draught to the pits be short, by changing him alternately from an empty to a full one, but this only applies to the Scotch and Irish system of draught by single carts and horses. The general mode of securing the crop in pits in the field is the safest. In making the pits—improperly so termed, for the base is only sunk a few inches, and the potatoes are raised considerably in the heaps—the only caution to be observed is that furrows should be cut on all sides to prevent water from lodging or penetrating inwards, and that the earth thrown up and over them to the depth of four or five inches, should be well beaten with spade or shovel to exclude moisture and frost. The potato-stalks, however apparently dry, should never be laid between the potatoes and the earth in these accumulations, for they soon ferment and rot, and injure all the potatoes in contact with them. Straw is at least useless. The length of the pit depends on circumstances, but the breadth should not exceed four feet, as large accumulations are most liable to fermentations.

The only decided disease of the potato, besides the dry rot, is 'the curl,' which is an imperfect formation, and was first generally observed in 1764, when it gave rise to various conjectures and unprofitable discussions: the cause is yet unknown. One thing however is clear, that from a crop of which any part is intended for seed, all the plants affected with curl should be carefully separated before the general removal commences. The dry rot, or decay of the set, which during recent years so fearfully prevailed in many parts of the United Kingdom, is also still unexplained as to its real cause, though the press has teemed with essays and very plausible theories respecting it. The same malady was remarked for many years, as appears by the 'Philosophical Transactions of the Bath Society,' and we have reason to think, in seasons similar to those which we have experienced in latter years. The set, though apparently sound when planted, has either failed to germinate at all and rotted away, or has feebly and partially thrown out its sickly shoots. The most contradictory causes have been assigned: over-ripening in the preceding year; under-ripening; fermentation in the pits; fermentation of the set in the ground when placed in contact with hot dung (which is utterly absurd, for when in the ground no injurious fermentation can arise); very hot weather, great drought, hot sun, cold parching wind, dry and heating manure, sea-ware, which is always damp; exhaustion of the kind from a long course of culture, contradicted by many instances in which it appears that the produce of the same variety—for instance the apple—has been successively cultivated during sixty-five years without any failure; or the loss of vitality from prematurely shooting.

If potatoes have fermented in their accumulated state, they would bear obvious evidence of it and therefore be rejected. Fermentation cannot be the true cause in every or even the majority of cases, nor does the failure probably proceed from insects in the eyes, as has been suggested, for if so, it is difficult to account for the fact that sets from the same heap planted at one part of the day have totally failed, while others put into the ground at another have pushed forth healthy shoots. As to decay in the land from the contiguity of fermenting manure, 'how is it to be proved that the gases evolved by fermenting manure can injure the sets? fermenting manures would rather stimulate by their warmth, and excite their growth by the aliment which their essential qualities, carbon and ammonia, supply to plants. Why do not the gaseous exhalations from rank and fermenting hot-beds destroy the tender plants which are raised in them?' (Doyle's *Cyclopædia of Practical Husbandry.*)

The same causes which are severally assigned for the total or partial failure of the potato in numberless instances, and to a most distressing extent in Ireland, have existed since the culture of the potato commenced, but without the effects deplored, which have only prevailed within a very recent space of time. But from the frequent and searching investigation of the subject by the most competent and practical men, a preventive against the failure has been ascertained, namely, the planting of entire tubers. When the cut sets have failed, the entire tubers have resisted premature decay; whether it arises from atmospheric influence or debility of constitution, or from any of the conjectured causes, the entire tubers resist these noxious influences, and germinate healthily and freely. All reports agree on this point; there is no risk in this case, if the tubers be sound when planted; and it may be added, that in all stages of their growth, the uncut tubers maintain a decided superiority and yield a corresponding produce.

The farina of the potato, properly granulated and dried, is sold in our shops as tapioca, to which it bears the closest resemblance both in appearance and essential properties. For confectionary the flour is so delicately white, and it is so digestible and nutritious, that it ought to be in more general use, among the children of the poor especially, in the winter season, when they so rarely enjoy the luxury of milk; and the cost is not more than a sixth or seventh of the price of tapioca or arrow-root, if it be made at home. Few housewives are ignorant of the method of obtaining it by the use of a common hand-grater and sieve; but for yielding larger supplies some machinery is necessary.

POTEMKI'N GREGORY ALEXANDROVITZ, PRINCE, born near Smolensk, of a noble though poor family, entered the army at the age of eighteen, and obtained a cornetcy in the Russian guards. When the Revolution took place at Petersburg, in 1762, by which Peter III. was dethroned, and his wife Catharina proclaimed empress of all the Russias, Potemkin took the part of Catharina, and was very active in bringing his regiment over to her cause. He was duly noticed by Catharina, and after some time he became her favourite. But he had better claims to favour than mere personal attractions, for he had great natural abilities, comprehensive ideas, and great presence of mind: the empress conceived a real esteem for him, which survived the loss of her affection. Unlike her other favourites, Potemkin, when no longer her personal favourite, continued to be the confidential minister and trusty adviser of his sovereign, and was for many years the most influential man in Russia. His views were turned towards the south, and he encouraged Catharina to extend her dominions in the direction of Turkey. He was a main promoter of the war against the Porte in 1771-2, in which the Crimea and Kuban were dismembered from the Ottoman empire, and by which Russia acquired a footing on the coast of the Euxine. He was afterwards the means of inducing Heraclius, czar or prince of Georgia, to do homage to the empress, and receive a Russian garrison at Tiflis. He also induced Solomon, the sultan of Imiretia, to do the same. Lastly, he took advantage of a dispute with the khan of the Crimea, who had been acknowledged as an independent sovereign, to reduce that fine province under the subjection of Russia, in the years 1784-5. The countries dismembered from the Ottoman empire were formed into a Russian government, which received the classical name of Tauris, or Taurida, and Catharina bestowed upon Potemkin, for his services, both military and diplomatic, the surname of Taurisschesky. Conformably to this name, the magnificent palace which Catharina had built for him at Petersburg was styled the Taurian or Taurida palace. In 1787, war having broken out again between the Porte and Russia, Potemkin was made commander-in-chief of the Russian armies, with several experienced generals under his orders, among whom was Suwarrow. In 1788, Oczakow was taken by the Russians, and Ismael in the following year. The Russians occupied Moldavia, Bessarabia, Wallachia, and part of Bulgaria. In 1791, Potemkin left the army, and returned to Petersburg to enjoy his triumphs. He gave a magnificent entertainment to the empress and her court in the Taurida palace, which is well described by Tooke and the other historians of Catharina. It was a gorgeous display, worthy of the Eastern fairy tales. The empress, contrary to her custom, stayed till midnight, in order not to disturb the pleasure of her host and of the company. As she was going to retire, she turned to Potemkin to express her satisfaction, when the prince fell on his knee, and seized her hand, which he bedewed with tears. This was a burst of genuine feeling, and in a man who had long appeared a stranger to such emotions. Shortly after, Potemkin quitted Petersburg to return to the army. He attended the congress of Jassy in 1792, but the negotiations had already begun, and were carried on between Prince Repnin and the grand-vizier. Potemkin fell ill at Jassy of an epidemic which was raging at that time. When Catharina heard of it, she sent two of her first physicians to attend on him; but he would pay no attention to their advice, and indulged even more than usual in his intemperate manner of living. His disease gaining ground, he thought of removing from Jassy to Nicolaieff, a town which he had built at the confluence of the Yekol with the Bog, but he had scarcely travelled ten miles when he felt himself dying. He was taken out of his carriage, and laid down on the grass by the road side, under a tree, where he expired in the arms of his niece the Princess Branicka, in October, 1792, at 52 years of age. His remains were moved to Kherson, where a mausoleum was raised to him by order of Catharina. The following is a list of his titles and offices at the time of his death:—he was field-marshal of Russia, chief general of the cavalry, great-admiral of the Euxine and Caspian seas, governor-general of Taurida and Ekatarinoslaf, master of the ordnance, inspector-general of the army, grand-hetman of the Cossacs, adjutant-general and chamberlain to the empress, colonel of several regiments, and knight of many orders.

Potemkin was a man of contradictions and eccentricities; of great natural abilities, vast conceptions, and of extensive though not deep information. He had a most active mind, with an indolent habit of body. Enthusiastic in his youth, he lived to be satiated with every kind of excitement, and weary of all that this world can afford. He served however to the last his country and his sovereign with zeal, and he was the means of establishing the power of Russia on the coasts of the Euxine. His character was peculiarly Russian, and both his faults and his good qualities were national.

POTENTILLA (so called from its potency in medicine, some of the species, especially *P. reptans*, having been employed as astringents) is a large rosaceous genus, the species of which inhabit exclusively the cooler parts of the world, and prefer the coldest. Most of them are herbaceous perennials, a very few only forming shrubs. Their flowers are usually yellow, in a few species they are white, and very rarely they are purple. Many of the species are cultivated on account of their ornamental appearance. As a genus Potentilla differs from Fragraria (or the strawberry) in nothing except the receptacle of its fruit being dry and hard, instead of succulent and much enlarged. Such of the species of Potentilla as have fingered leaves are popularly called cinquefoils.

POTERIOCRINI'TES. [ENCRINITES, vol. IX., p. 391.] N.B. In Mr. Murchison's great work on the *Silurian System*, vol. ii., p. 672, pl. 17, fig. 3, Professor Phillips describes and figures a new genus of Encrinites under the name of *Hypanthocrinites*, observing that in it the lowest plates clearly seen appear to correspond to the first costals of the genus *Actinocrinites*, and that the pelvic plates were probably small. The column he thinks was probably short; its joints are prominent in the middle, and thinnest near the body. The Professor observes, in conclusion, that the arrangement of the lower plates in *Eucalyptocrinites* of Goldfuss is so very similar to that above noticed, that it is difficult to suppose the genera so entirely distinct as would be the case if *Eucalyptocrinites* be really, as Goldfuss supposes, destitute of a column. Quære tamen.

POTHIE'R, ROBERT JOSEPH, born at Orleans in 1699, studied in his native town, and adopted the profession of the law. He was made conseiller au chatelêt (court) of Orleans, and was afterwards appointed professor of French law in the university of that city. He was an intimate friend of the chancellor D'Aguesseau, and he is considered one of the most distinguished civilians that France has produced. Pothier wrote many professional works, but he chiefly devoted his labours to extend the study of the Roman law. With this view he published his edition of the 'Digesta,' which is entitled 'Pandectæ Justinianeæ in Novum Ordinem Digestæ; cum Legibus Codicis et Novellis quæ Jus Pandectarum confirmant, explicant, aut abrogant,' 3 vols., fol., Paris, 1748-52. The work contains an introduction on the history of the Roman law, a Commentary on the laws of the Twelve Tables and on Hadrian's perpetual Edict, and is accompanied by notes and tables of contents. After Pothier's death, his friend Guyot published a new edition of his 'Pandects,' in which he inserted many corrections and additions that Pothier had made in MS. on a copy of the former edition, and also a biographical notice of Pothier, 3 vols. fol., Lyon, 1782. Other editions of Pothier's 'Pandects' have since appeared; among which there is one with a French translation by Bréard Neuville and Moreau de Montalin, Paris, 1810.

Pothier was the author of numerous treatises on various branches of law: 'Traité du Contrat de Mariage;' 'Traité des Contrats Aléatoires;' 'Du Contrat de Vente;' 'Du Contrat de Change et Billets de Commerce;' 'Du Contrat de Louage;' 'Du Contrat de Louage Maritime et du Contrat de Société;' 'Traité des Obligations,' which has been translated into English, with the following title, 'A Treatise on the Law of Obligations or Contracts, translated from the French by W. D. Evans,' 2 vols. 8vo., London, 1806; 'Traité du Domaine de Propriété, de la Possession, et de la Prescription.' These and other treatises of Pothier have been collected in one work under the title 'Traités sur Différentes Matières de Droit Civil appliquées à l'Usage du Barreau et de la Jurisprudence Française,' 4 vols. 4to., Orléans, 1781.

The compilers of the new French Civil Code under Napoleon made great use of Pothier's treatises, as is shown in a useful work by M. Ledru, a French civilian, entitled 'Le Pothier des Notaires, ou Abrégé de ses divers Traités, avec l'Indication de ceux des Articles du Code Civil dont on y retrouve les Dispositions,' 4 vols. 8vo., Paris, 1823. On this subject Savigny remarks, 'It is generally known that Pothier is the polar star of Roman law to modern French jurists, and that his writings had a most immediate influence on the code. I am very far from depreciating Pothier: on the contrary, the jurisprudence of a nation, in which he was one of many, would be very well directed. But a juristical literature, in which he stands alone, and is honoured and studied almost as an original authority, is an object of pity.' (*Vom Beruf*, &c., p. 60.) The treatise on Contracts, which is perhaps the best known of Pothier's works to English lawyers, may be comprehended within the same judgment. It is a respectable and useful work, but it should not be studied as an authority. Among the other works of Pothier is the 'Coutûme d'Orléans,' 1760, which is one of the most complete treatises on the old French law.

Pothier died at Orleans in 1772. He left many works in MS. which were published by his friend Guyot: 'Œuvres Posthumes de R. J. Pothier,' 3 vols. 4to., Paris, 1777, containing, among others, treatises 'Des Successions,' 'Des Donations Testamentaires,' 'Des Donations entre Vifs,' 'Des Cens,' 'Des Fiefs,' 'De la Procédure Civile et de la Procédure Criminelle.'

It is a merit of Pothier that his learning was enlightened by a strong sense of justice, morality, and religion. He never gave his sanction to any of the unjust and cruel practices of the old French judiciary system, such as the torture. In his treatise 'De la Procédure Criminelle,' sect. iv., art. 2, he exposes the absurd custom which existed in his time in France, and still exists in some European states, of obliging the accused, at the beginning of his interrogation or examination, to take an oath to reveal all the truth, thus inducing him to perjure himself in order to save his life: 'a custom,' observes Pothier, 'which has been reprobated by many divines and moralists, and which appears to be borrowed from the code of the Inquisition.'

POTIDÆA. [MACEDONIA.]

POTO'MAC. [MARYLAND; VIRGINIA.]

POTO'MIDA, Mr. Swainson's name for a subgenus of Dr. Turton's genus *Mysca*, placed by Mr. Swainson in the subfamily *Unioninæ*, family *Unionidæ*. (*Malacology*.)

POTOROO'. [MARSUPIALIA, vol. xiv., p. 462.]

POTOSI', a town in South America, in the republic of Bolivia, and in the department of Potosi, is built on the south-western declivity of the Cerro de Potosi, in 19° 36′ S. lat. and 65° 20′ W. long., at an elevation of 13,265 feet above the level of the sea. This town, which a hundred years ago, when the mines of the Cerro were in a flourishing state, is said to have contained 100,000 inhabitants, contained, in 1826, a population not exceeding 12,000, about half of whom were Peruvian Indians. It is built on an uneven site, and the streets are consequently irregular, but they are tolerably wide and clean. Many of the houses are large, and most of them substantial. On one side of the principal square stands the government-house, a long low range of buildings, including the courts of justice, the gaol, and the guard-house. Opposite to it is the cathedral, an immense edifice, still unfinished, which has very little claim to architectural beauty. The mint also is very large, but far from being a fine building. The great square contains a monument erected in honour of Bolivar. The town is well supplied with meat, fruits, and vegetables, though the surrounding country is barren and exhibits few signs of vegetation. The Indians live mostly on potatoes. The climate of Potosi presents the changes of the four seasons of the year every day. It commonly freezes at night, and the morning is piercingly cold; the forenoon is like the finest March day in England; from noon to about two or three o'clock it is extremely hot in the sun, but in the shade it is not only cool, but very cold. The evenings and the early part of the nights are usually serene, and sometimes mild. It is a healthy place, but the extreme rarity of the air, in consequence of the great elevation above the sea-level, produces a difficulty of respiration called *zarochi*, to which even the natives and animals are subject.

The Cerro of Potosi rises to the elevation of 16,037 feet above the sea. It is of a reddish brown colour, and has the shape of a perfect cone, but is not volcanic, as has been supposed. It does not produce a blade of grass: the whole mountain seems to consist of silver-ore of different degrees of richness. It was discovered that this mountain contained silver-ore by an Indian, in 1545, who being in pursuit of a lama upon the steep declivity, in order to save himself from falling caught hold of a shrub, which being torn from the soil, exposed a mass of solid silver at the roots. From that time to the present day the mines have been worked. The produce of these mines from 1556 to 1800 amounted to the enormous sum of 823,950,508 Spanish dollars, or 185,388,864*l*. The greatest produce was in 1593, when it amounted to 7,858,893 Spanish dollars, or 1,768,251*l*. In the middle of the seventeenth century the produce began gradually to fall off. A few years previous to the War of Independence the produce was still about 8000 marcs (4000 pounds avoirdupois) of pure silver weekly, but during the war the extensive machinery was destroyed, and in 1826 Temple estimated the annual produce at 125,000*l*. only, or 1500 marcs weekly.

(Humboldt, *Essai sur la Nouvelle Espagne*; Temple, *Travels in various Parts of Peru*.

POTOSI, SAN LUIS DE. [MEXICAN STATES.]

POTSDAM is one of the two governments which form the province of Brandenburg. It includes the district of Berlin, which, though only 29 square miles in extent, has been called a government by Hassel and others. This government is situated between 51° 50′ and 53° 35′ N. lat. and between 11° 10′ and 14° 24′ E. long. It is bounded on the north by Mecklenburg-Schwerin and M.-Strelitz, on the north-east by Pomerania, on the east by Frankfort, on the south by Saxony, on the south-west by Anhalt-Dessau, on the west by the province of Saxony, and on the north-west by Hanover. It is formed of the districts formerly called the Priegnitz, the Uckermark, and several circles of the Middle Mark, and is divided into thirteen circles, besides the district of Berlin. The area is 8000 square miles, and the population (1837) 1,169,706; that of Berlin is 265,394. This tract is an extensive and low plain, varied only occasionally by slight elevations. The soil, though for the most part a light sand, contains some fertile spots, especially on the banks of the rivers. The climate is generally healthy. The principal mineral is bog-iron ore, which however does not yield above 20 per cent. The inhabitants are industrious, and carry on manufactures of woollen, cotton, and linen. The principal towns, besides Berlin and Potsdam, are Brandenburg, with 13,283 inhabitants; Prenzlau, with 10,508 inhabitants; Charlottenburg, 6376 inhabitants; New Ruppin, 7415 inhabitants; Wittstock, 6113 inhabitants; and Spandau, 6753 inhabitants.

POTSDAM, the capital of the government, the handsomest town in the Prussian dominions, next to Berlin, is situated at the confluence of the Ruthe and the Havel, on an island about 18 miles in circumference, formed by the Havel, some small lakes, and a canal. It became the occasional residence of the court about the end of the seventeenth century, but it is indebted for its chief improvements to Frederic II., before whose time the old town consisted of only four streets. Frederic built almost the whole of the new town, and had several of the new streets made to look like rows of palaces, the fronts being all of stone. The streets are regular and broad, and there are some good squares; but the whole is on too large a scale for the population, and in the absence of the court, or when the garrison is reduced, the town seems deserted. It is surrounded by a rampart, and has nine gates, of which the Brandenburg gate is a handsome triumphal arch copied from the arch of Trajan at Rome. Of the seven bridges over the Havel and the canal, the finest is the Teltow bridge, which is 600 feet long and 30 wide, and consists of 8 iron arches resting on massive stone pillars. Of the numerous fine buildings the following seem to be the most worthy of notice:—1. The Royal Palace, in the old town, was begun by the elector Frederic William I., and completed by Frederic II. It is an oblong parallelogram, three stories high, adorned with colonnades of the Corinthian order. The main entrance is towards the old market-place, a handsome square, in the middle of which there is an obelisk of red and white marble 75 feet high, the four sides of which are adorned with busts of the elector Frederic William and of kings Frederic I., Frederic William I., and Frederic II. This palace has extensive gardens along the river. 2. The Town-hall, which Frederic II. caused to be built in 1754, on the model of that of Amsterdam. 3. The Theatre. 4. The new great poor-house and infirmary; and 5, the Military Orphan Asylum. Of the churches, we may notice the garrison church, which contains the tombs of Frederic William I. and Frederic II.; the church of the Holy Ghost, with a fine steeple 280 feet high; and the French Protestant church, built on the plan of the Pantheon at Rome. There are extensive barracks, and a large building 660 feet in length and 75 feet in breadth, for exercising the troops in bad weather. Potsdam is the seat of the government, and of all the offices connected with it, and has a great number of useful and charitable institutions. The principal manufactures are silk, cotton, linen, woollens, leather, hats, hosiery, musical instruments, and carriages. In the manufactory of small arms, the musket-barrels, made at Spandau, are fitted with stocks, &c., and finished for use.

In the vicinity of Potsdam are the Brauhausberg with agreeable promenades; the Pfaueninsel (Island of Peacocks) in the river Havel, which is 2000 paces long and 500 broad, with fine grounds laid out in what the Germans call the English style, and containing many foreign animals; the Russian colony Alexandrewna, established in 1826; and three royal palaces: (1) Sansouci, the favourite residence of Frederic II., which is only one story high, with a circular pavilion at each end, in one of which the king's library remains exactly in the same state as at his death. The palace stands on the slope of an eminence and commands a fine prospect. The gardens are very extensive, and laid out with much taste. (2) The Marble Palace; and (3) the New Palace, a very magnificent building founded by Frederic II. The population of Potsdam on the 1st of January, 1838, was 25,560, without the garrison, which varies from 6000 to 10,000 men.

(Dieterici, *Uebersicht des Verkehrs im Preussischen Staate*, &c., 1838; Hörschelman: Cannabich; Stein; Müller, *Geograph. Wörterbuch des Preussischen Staates*, 1836; Heidemann, *Topographisch-Statistisches Wörterbuch der Preussischen Monarchie*, 1836; Schlieben, *Gemälde der Preussischen Monarchie*, 1830; Official Population Returns for 1837.)

POTT, PERCIVALL, was born in London in 1713. He was intended for the Church, in which, under the patronage of his relation the bishop of Rochester, he had good prospects of preferment; but nothing could induce him to give up his inclination for surgery. He was accordingly, in 1729, apprenticed to Mr. Nourse, one of the surgeons of St. Bartholomew's Hospital, and one of the few by whom anatomical lectures were at that time delivered. In 1736 he commenced private practice: in 1745 he was elected assistant surgeon, and in 1749 full surgeon to St. Bartholomew's Hospital. In 1756 he received a severe compound fracture of his leg, and during the confinement which the accident rendered necessary, he commenced writing the surgical works for which he has since been justly celebrated. His first publication was a 'Treatise on Ruptures;' in 1757 he wrote on Hernia Congenita, in 1758 on Fistula Lacrymalis, in 1760 on Injuries of the Head, in 1762 on Hydrocele, in 1765 on Fistula in Ano. At subsequent periods he published observations on fractures and dislocations, cataract, polypus of the nose, chimney-sweeper's cancer, mortification of the toes, and on paralysis from disease of the spine.

In 1787, his time being fully occupied in private practice, he resigned his hospital-surgeoncy, having served the institution for nearly half a century. In 1788 he died.

Mr. Pott's writings are essentially practical, and full of common sense; and the clearness and purity of their style contributed in no slight degree to make them everywhere acceptable. Probably no person of his time had more influence in the improvement of surgery, not indeed by such scientific principles as were established by his early pupil John Hunter, but by the introduction of judicious and simple rules of practice in every subject to which he directed his attention. Many of these rules are still strictly followed both in this country and on the Continent, and some of the diseases which were first described by him still bear his name, as Pott's gangrene, Pott's fracture of the leg, &c.

His works were published collectively in several forms after his death; the best edition is that edited by his relation and successor Mr. (afterwards Sir James) Earle, in 3 volumes, 8vo., London, 1790, and in subsequent years.

POTTER, PAUL, an admirable painter of animals, the son of Peter Potter, an artist of moderate ability, was born at Enkhuysen, in the year 1625. He received the rudiments of his art from his father; and such was his progress, that at fifteen years of age he was held in the highest degree of estimation, and was considered one of the most promising artists of his time. He established himself at the Hague, where he was greatly patronised by Maurice, Prince of Orange, for whom he painted some of his finest pictures. Here he married, in 1650, the daughter of an architect named Balkanende, in whose house he resided, and afterwards removed to Amsterdam. He was naturally of a delicate constitution, which by his unremitting attention to his art he greatly impaired, and died on the 15th of Jan., 1654, in the twenty-ninth year of his age.

The chief excellence of Paul Potter consisted in his painting of cows, sheep, goats, and other animals, in which he makes his landscape a subordinate part, but the animals are executed with a correctness of drawing and a delicacy of touch perfectly astonishing. His pictures usually exhibit a brilliant effect of sunshine, in which the skies, trees, and distances evince a remarkable freedom of hand, whilst the principal parts are finished with the utmost delicacy and minuteness. He sometimes painted as large as life, but succeeded best in cabinet-sized works. One of the most exquisite of the latter is in the collection of the Marquis of Westminster, at Grosvenor-house. It is a landscape with cattle and figures. The scene is a view near the Hague, and the picture was painted for Van Slinglandt, in whose possession it remained till 1750, when it was bought by a collector and taken to Paris, and was afterwards sold to Mr. Crawford of Rotterdam for 1350*l.*, at a public auction in that city. The size is 1 foot 6 inches, by 1 foot 8 inches wide. The marquis is stated to have given 900 guineas for it. Though the preference is given to his smaller pictures, there is one of a herdsman and cattle, the size of life, which formerly belonged to the Prince of Orange, and is now in the gallery of the Louvre; it is designed and executed with surpassing truth and character, and gained for the painter the title of the Raffaelle of animals.

Paul Potter designed every object from nature, and it was his constant practice, in his walks in the fields, the only recreation he allowed himself, to sketch every object that attracted his attention; hence in his pictures he ensured the greatest fidelity to nature. Like other Dutch painters, his subjects are sometimes grossly offensive, but in all his cabinet works the execution is deserving of the very highest praise. There are many beautiful etchings by him executed in a masterly style: some are marked *Paulus Potter f.*, and others *in. et f.*, and a great number of his designs have been spiritedly etched by Mark de Bye. (Bryan's *Dict.*; Pilkington's *Dict.*; *Biographie Universelle.*)

POTTER, JOHN, D.D., born 1674, died 1747, an eminent prelate of the English church, was born at Wakefield in Yorkshire, where his father, Mr. Thomas Potter, was a linendraper, and educated in the grammar-school of that town. At the age of fourteen he entered as servitor of University College, Oxford; took the degree of B.A. in 1692, and in 1694 became fellow of Lincoln College. He had by this time made great attainments in classical learning, and though so very young, was encouraged by Dr. Charlett, the master of University College, to publish a collection which he had made of various readings and notes on the treatise of Plutarch 'De audiendis Poetis.' This was published in 1694, and was soon followed by a similar work, namely, various readings and notes on an oration of Basil. His greater works soon followed: his edition of Lycophron, and his 'Archæologia Græca,' or Antiquities of Greece, both published in 1697. It is almost incredible that works such as these could have been produced by a young man scarcely past his twenty-third year. His Lycophron was reprinted in 1702, at which time he had gained a continental reputation, as appears by his dedication of it to Grævius. His 'Grecian Antiquities' soon became and still continues to be a popular book, having been often reprinted; but it is now far behind the present state of philological knowledge. It contains abundant proofs of the author's learning, but it also shows that he possessed little critical discrimination, a fault however which he shared in common with many other scholars of that time. It was published, in Latin, in the 'Thesaurus' of Gronovius. In 1698 he entered into holy orders, and from that time his studies appear to have been almost exclusively professional, and he passed from one preferment in the church to another till at last he reached the highest dignity. Archbishop Tennison made him his chaplain, and gave him the living of Great Mongeham in Kent, and subsequently other preferment in Buckinghamshire and Oxfordshire. He became chaplain to Queen Anne, and Regius Professor of Divinity in the university of Oxford with a canonry of Christ Church, and in 1715 bishop of Oxford. This he was said to owe to the interest of the Marlborough family. In the same year he published an edition of the works of Clemens Alexandrinus, in 2 volumes, folio, which is still the best edition of that author. His other publications were sermons and charges, and a discourse on church government. In 1737 he was made archbishop of Canterbury, which high station he supported with much dignity to the time of his death. His theological works were published at Oxford, in 3 vols. 8vo., 1753.

POTTER, ROBERT, was born in 1721. He was educated at Emanuel College, Cambridge, and took his degree of B.A. in 1741. He was successively appointed vicar of

Scarning in Norfolk, prebendary of Norwich, and vicar of Lowestoft and Kessingland, in the diocese of Norwich. He died August 9th, 1804, in his eighty-fourth year.

Potter published a volume of poems in 1774, and translations of Æschylus in 1777, of Euripides in 1781-82, and of Sophocles in 1788. Of these translations that of Æschylus is the best, and perhaps gives to an English reader as good an idea of the original as a translation can supply. Potter also published 'An Enquiry into some Passages of Dr. Johnson's Lives of the Poets,' 1783; 'a translation of 'The Oracle concerning Babylon' and the 'Song of Exultation' from Isaiah, c. xii., xiv, 1785; and 'A Sermon on the Thanksgiving for the Peace,' 1802.

POTTERY. As porcelain is only a finer kind of pottery, the following description will comprehend the mode of manufacturing both articles.

In the beginning of the last century, it was ascertained by experiment that the earths alone are infusible, but that when silex is combined with aluminous earth, and subjected to a strong fire, it unites chemically with the clay, as an acid to a base; and that when a third earth, having alkaline properties, as lime, magnesia, or barytes, is added, a more complete change is effected, and a vitrified body is produced, resembling in density and fracture many natural gems. When the earthy materials are free from metallic matter, a perfect porcelain is thus produced. It was found that seven parts of silex, six parts of aluminous earth, and two parts of an alkaline earth, would produce such a body. On this principle the Germans and French founded their china manufactures. In England the enterprising spirit of Wedgwood wrought a complete revolution in the art, and by bold experiments, guided by his knowledge of mineralogy and chemistry, he laid the sure foundation for all those improvements which have raised the earthen manufactures of this country to an eminence which our continental neighbours are now labouring to rival.

We shall now describe the practice of a pottery as carried on in Staffordshire, where the trade has long flourished to a great extent, and now affords subsistence to a population of seventy thousand persons.[*]

The materials for earthenware are reduced to the consistence of cream, in which state they are called *slips* (slops): this fluidity is necessary to ensure the perfect mixture of all the ingredients, and their mutual chemical action in the fire. The basis of the composition is a clay from the plastic-clay formation in Devonshire or Dorsetshire, to which is added ground flint, which gives whiteness and solidity to the goods. For the better kinds, a portion of China-clay, or decomposed felspar from Cornwall, is added, together with a small quantity of ground white granite. By this means the density of the ware is increased, greater purity of whiteness is obtained, and also a degree of vitrification which makes the ware sonorous when struck.

The clays are thrown into their several vats sunk in the ground, where they are blended with water, and sifted, through fine silk lawns, into other receptacles, and then diluted with water until a pint measure of clay slip weighs exactly twenty-four ounces; flint and granite slips are made to weigh thirty-two ounces; thus the potter mixes by measure, while his calculations are formed upon the known weights of the several earths that he is using. The mixture is made in a vat, the sides of which are perfectly vertical, and the quantity of each material to be used is marked by notches on a rod or guage-stick, which the foreman, who superintends this process, dips into the vat, while the slipmaker pours in the slips, until each rises to its proper mark on the mixing-rod. The whole is now thoroughly incorporated, and it is lifted by a pump into a vessel, from which it descends, through a tap, into a silk sieve, which is kept in constant agitation while the fluid is passing through it. This process of sifting is repeated once or twice more, in order to ensure not only the fineness of the body, but the complete amalgamation of all its parts. The slip is then pumped on to a boiler, or slip-kiln, the bottom of which is formed of large flat fire-bricks, under which four or five parallel flues pass from the fire-place to a high chimney. The water is then evaporated, until the boiling mass is brought to a proper consistency for working; but, the steam having given it a cellular and porous texture, it requires to be beaten or wedged until the air is driven out and a section of the mass, when cut, is smooth and compact.

The business of the slip-house requires the utmost vigilance on the part of the potter. Ruinous losses have often been suffered through inattention to this department, and the error has not been detected until the goods have been finished, when the circumstance of the glaze peeling off, or the body of the ware splitting, warns the unfortunate manufacturer to look to his materials, or the bad management of the slip-house.

The following are useful and safe forms for the mixture of earthenware bodies.

Cream-colour or *Printed Ware.*—

Dorset clay . .	56 or	60 or	66
China clay . .	27	18	17
Flint . . .	14	20	17
Cornish granite .	3	2	

Drab-coloured Ware is made of the fine grey marl found between the coal strata, which burns to a cane-colour in the oven; or a white body, as above, is stained with oxide of nickel, which gives it a greenish drab tint; or with oxide of manganese.

Drab body.—	Cane marl .	32 or	— or	56 or	26
	Dorset clay .	22	43	20	46
	Cornish granite	45	50	24	25
	Oxide of nickel	1	7	—	—
	Manganese	—	—	—	3

The granite in the above bodies gives great density and a very close flinty fracture.

Brown or Chocolate bodies are made with a basis of the red ochreous clay, obtained from the red-marl formation above the coal strata. A great variety of tints may be obtained by judicious combinations of oxides of iron, as umber, calcined copperas, bole, &c.

Brown.—	Red clay . .	83 or	60
	Dorset clay . .	13	30
	Flint . . .	2	10
	Manganese . .	2	

Egyptian Black, for tea-pots, ink-stands, &c., is made in the same way, but with a larger portion of the oxides of iron and manganese.

Black.—	Red clay . .	45 or	34
	Dorset clay . .	36	42
	Manganese . .	13	12
	Protoxide of iron .	6	12

Blue bodies are produced by the mixture of a small quantity of oxide of cobalt with a fine white body; when made of vitrescent materials, so as to give a gem-like surface without glazing, it is termed jasper. This beautiful article is well known by the splendid productions of Mr. Wedgwood, whose medallions and cameos maintain their unrivalled excellence to the present time.

Jasper bodies.—

Sulphate of barytes	48 or	Carbonate of barytes	34
China clay . .	16	China clay . .	15
Dorset clay . .	24	Dorset clay . .	15
Flint . . .	10	Cornish granite .	33
Gypsum . .	2	White lead . .	3

These mixtures give a fine white body for ornaments, which may be stained blue by the addition of from one-third of a part to one per cent. of oxide of cobalt, according to the strength of tint required; or a green jasper may be produced by staining with protoxide of chrome.

A body called turquoise has been manufactured to a great extent for a few years past. It is nothing more than a good white body, stained with a mixture of oxide of cobalt combined with a large proportion of oxide of zinc; when glazed, it has the peculiar milky tint of the gem after which it has been named.

In this manner, by a proper combination of metallic oxides, either as existing in earthy materials, or prepared from their metals, an infinite variety of coloured bodies may be produced. They are usually prepared on slip-kilns of small dimensions, the bottoms of which are covered with a layer of plaster of Paris, if used for the finer colours.

Having described the operations of the slip-house, we proceed to those manipulations by which the clay is formed into vessels. Round articles, which may be turned upon a lathe, have their form given upon the thrower's wheel, which is a lathe with a vertical spindle, having a small round table on the top, at which the thrower sits. He receives the clay prepared to the proper size by a woman, called the baller, and throws it upon the whirling table between his knees, which is put in motion by the wheel-woman, whose eye watches every motion of the thrower, and regulates the velocity of the work with perfect accuracy. The thrower first draws the clay up into a pillar, then depresses it into a flat cake, until the whole mass has been drawn into a circular arrangement of all its parts. He then opens the hollow of the vessel with his thumbs, and continues to draw out the clay, or press it inwards, until the desired shape is given to it. It is then cut from the table by a brass wire, and placed on a board, which, when full, is carried into a stove-room to harden.

---

[*] The subject of pottery has been partly treated under EARTHENWARE. As this article will explain the processes of this important branch of industry in the English potteries at the present time, it has not been considered necessary to avoid all repetition of what may have been said under another head a few years ago.

When a number of vessels of the same size are to be thrown, a guage is fixed so that its point just touches the top edge of the article when it is revolving; this fixes both the height and diameter of all that are made after.

When the vessels are sufficiently hardened, they are turned upon a lathe similar to that used by wood-turners. The turner dexterously shaves away the clay to the proper thickness, and works the mouldings, &c., polishing the whole with a steel burnisher. Eccentric movements are sometimes used, by which the turner produces ornamental lines and variations of the surface; but this kind of work having lost its value owing to the caprice of fashion, there are now few workmen who are able to execute such beautiful specimens of the turner's art as were common about forty years ago. The shavings of clay are carefully returned by the turner to the slip-house, where they are blended with new clay, the ductility of which is much improved by the mixture.

The turner frequently ornaments bowls, jugs, &c. with a coating of various coloured clays, which are sometimes blended with each other, so as to give a marbled surface. By these earthy pigments he produces an infinite variety of patterns. This kind is called dipped ware.

Such articles as require handles and spouts are then passed to the handler, who makes those appendages in plaster moulds, and sticks them to the vessels with liquid clay. Plain handles are pressed by a syringe through a hole of the proper size and form, and as the clay comes through in long strings, it is cut off, and bent into the desired shape for the handle.

Thrown and turned goods are sometimes ornamented with figures in relief, which are made out of flat moulds by children, and fixed upon the ware by workmen, who, having carefully adjusted each figure to its place, run a little water under it with a camel-hair pencil, which unites it to the surface of the pot. Goods of an oval or angular shape, which cannot be turned, are made by pressing clay into plaster moulds, which give the outside form to the vessels. For this purpose the mould is made in two parts, and each is separately filled by laying in a cake of clay which has been beaten out to the proper thickness on a wet plaster-block; it is pressed into the mould by repeated blows from a ball of wet sponge, then squeezed into all the angular parts with the fingers, and smoothed with sponge, wet leather, and horn. When both sides of the moulds are thus lined with clay, they are joined together, and the man lays a roll of clay along the inside of the joining, which he works down until the whole is smooth and solid. The mould is then carried into a stove-room, and when the mould has absorbed the moisture, so as to release the clay, the work is then carefully taken out, and the empty mould returned to the stove previous to being filled again. The seam which remains on the outside of the vessel is removed by scraping and burnishing with wet horn: the handles and other appendages are then attached. This branch of the trade is called *hollow-ware pressing* or squeezing.

Flat-ware pressing is performed, on the contrary, by giving the shape to the goods by moulds which fit the *inside* of the vessel; plates, dishes, saucers, cups, and hand-basins are made on this principle by the English potter, with a dexterity which must be seen to be understood, and which excites the surprise of foreigners more than any other branch. The workman stands at a bench provided with a whirling-table similar to the thrower's, but which has its motion given by a horizontal pulley or jigger, which is turned by his young assistant. Close to his left hand is a *batting-block* of wet plaster and the mass of well-beaten clay from which he is working; immediately behind him is the stove-room, in which the moulds are ranged on shelves. All being ready, the plate-maker cuts his clay into lengths with a wire, and tears off a piece which he *batts out thin* upon his block by a stroke or two of his *batter* or plaster-mallet, and polishes the surface by pressing the side of a long smooth knife across it. During this process, which occupies but a few seconds, the boy has brought a mould, placed it upon the whirler, and taken his place at the handle of the jigger: the man places the clay upon the mould, and as it whirls, presses it down close with his hand; a profile, or earthenware tool which gives the form to the bottom of the plate, is pressed upon it as it revolves, the superfluous clay being cut off by a wire: the boy instantly catches hold of the mould thus covered with a coating of clay, and runs with it into the stove, places it on a shelf to dry, and returns with an empty mould; by which time his master has his clay prepared for another plate. Thus the operation is continued during working hours, the man and his little bare-footed assistant moving in perfect harmony, as if their several limbs were all under the volition of one mind. When sufficiently hardened, the bottom of the plate is polished, and when taken off the mould, the edges are smoothed and polished with moist leather. Cups, saucers, and hand-basins are now made by this process, instead of being thrown and turned as formerly. By this means they are supplied at a cheaper rate; one man and a boy being able to manufacture the articles which by the old mode requires the work of three men and three females.

Casting is resorted to when a mould is so intricate as to be difficult for the workmen to fill by pressing. Slip clay is poured into the mould, which rapidly absorbs the water; and a coating of clay is deposited upon the inside; the remaining fluid is then poured out or drawn with a syringe, and a thicker mixture is put in, and left rather longer than the first before it is withdrawn. The mould is then put into a stove to dry. Goods thus made are very light.

When completed by the workman, the goods are placed on boards to dry, before going to the biscuit-oven, in which they receive the first fire. The biscuit-oven is a cylinder of fire-brick, hooped with strong bands of iron, like a cask: the ordinary size in Staffordshire is fifteen feet in diameter, and about seventeen feet high, inside measure. Nine fire-places or *mouths* are built round it, from which short chimneys ascend within the oven; other flues, to conduct the flames, are ranged from the mouths under the hearth of the oven, and converge to a pit in the centre, from which the flames ascend through the midst of the oven: the heat is thus distributed as equally as possible, though an equal temperature throughout the whole oven can never be obtained. Goods which will bear the highest heat are therefore placed in the outer range, where they receive the full force of the flames entering from the mouths; while coloured ware, and other articles which could not sustain such a temperature, are placed in the inner parts of the oven. The ware to be thus burnt is placed in saggers made of crucible clay; in shape they resemble hat-boxes, and being piled in columns, each sagger covers the one beneath it, and protects the goods from the immediate contact of smoke and flame. The consumption of these saggers is very great, and forms an important item in the expenses of a pottery. When the oven is filled, the doorway is built up with fire-brick, and butted with a compost to prevent the access of air. Apertures are left at the front and back of the oven, closed with a brick, which can be withdrawn at pleasure; opposite these the *trial* saggers are placed, containing the pyrometers, which are drawn out at intervals by the fireman. These trial-pieces, or pyrometers, are hoops of Egyptian black clay, which when unburnt are of a red colour, but change in the fire, through all the intermediate tints, to a deep black: the well practised eye of the fireman can thus ascertain the state of the oven, and accelerate or check the ardour of the fire in the different mouths as he may think proper. The fire for a few hours is kept very moderate, until the goods are thoroughly dried and the whole contents of the oven warmed; the fire is then gradually increased, until the whole is brought to a white heat. In this operation a biscuit-oven consumes about eleven tons of coals; and requires near forty-eight hours for its completion. When the oven is cooled, the doorway is opened, the saggers brought out, and their contents submitted to a rigid scrutiny: all cracked and crooked pieces are rejected and thrown away; the workman in most cases loses his work, such bad articles not being paid for, and the master loses his materials. The ware is now called biscuit, and in this state goes to the printer or biscuit-painter to be ornamented.

The printing of earthenware is effected by transfer-papers from engraved copper-plates; the wear of which is so great as to give employment to a great number of engravers, and to form, together with transfer-paper, saggers, and coals, a large part of the prime cost of earthen manufactures. A set of engraved plates for a table-service commonly costs 130*l.* or 150*l.*; and will, with proper care, print 2000 dozen services before it wants recutting. The ink used in printing is made of linseed-oil, boiled with litharge, rosin, balsam of sulphur, or Barbadoes tar; almost every printer has his favourite recipe for making this tenacious oil, which is the vehicle of the colour to be used.

Blue colour is made of oxide of cobalt, mingled with flint or carbonate of lime so as to dilute it to the proper tint.

Lilac, of smalts 2 parts, manganese 1.

Brown, zaffre 2, litharge 2, antimony 1, manganese 1.

Red-brown, manganese 12, litharge 2, flint 2, glass 1, borax 1.

Orange, litharge 6, antimony 4, oxide of tin 1, oxide of iron 2.

Pink, subchromate of tin and carbonate of lime, equal parts.

Green, oxide of chromium. The tints varied with cobalt or tin.

Black, red-lead 60, antimony 25, manganese 15, fritted together; then add oxide of cobalt 40, oxide of tin 5.

The colour having been ground very fine, the printer blends it with his oil upon a hot stove, and filling the engraved plate with it, takes off the impression by the common rolling-press. The tissue-paper used for this purpose is first prepared with a solution of soap. As soon as the print is taken, a little girl cuts out the engraving with scissors and hands it to the transferer, who carefully places the print upon the biscuit-ware, which being absorbent, holds it with great tenacity. The transferer then passes it to her assistant, who with the end of a cylinder of flannel, tightly rolled and bound with twine, rubs the print with such force as to work the ink into close contact with the biscuit. The goods thus coated with paper are then put into a tub of water, and the paper being wiped off with a sponge, every minute point of the engraving is found accurately transferred to the earthenware. When dry, the goods are packed close in a large muffle, or kiln, round which a fire circulates, and brings the whole to a low red heat. By this means the oil is burned out of the colour, which would be injurious to the process of glazing which follows.

Some patterns are executed on biscuit by painters, who lay on the colours in gum-water, in which case the firing in the muffle is not required; but the choice of colours in this kind of painting is rather limited, as the heat of the glazing-oven and the chemical action of the materials of the glaze would be destructive to many colours which are used by the enameller upon the glaze.

The biscuit-ware, thus ornamented, is carried to the dipper, who dips each piece into the tub containing the finely-ground mixture which, when melted, forms the glassy coating to the ware. This glaze is blended in water, which, being absorbed by the biscuit, leaves a thin cover of glazing-powder upon the surface; a dexterous shake of each piece in a circular motion, as it emerges from the fluid, prevents the glaze from setting unequally, and throws off all that is superfluous. The composition of glazes requires much attention from the potter; if not sufficiently soft or fluent, the goods are deficient in brightness, and are rough at the edges; if too much so, the glaze runs down unequally, and is apt to craze. The glaze also requires to be adapted to the body which it is to cover and to the colour of the ornaments. Blues require a glaze which will supply oxygen, to bring the cobalt to the state of peroxide; while greens, on the contrary, should be covered with a glaze as free from oxygen as possible, and rather carbonaceous, in order to bring the chrome to the state of protoxide. The white-lead or nitre, therefore, which are beneficial in the first case, are very injurious in the latter.

The following glazes are excellent, and have been successfully used in the Staffordshire potteries; they must be ground very fine at the mill:—

Cream-colour glaze.—White-lead 66, Cornish granite 22, flint 12.

Printed-ware glaze.—White-lead 45, Cornish granite 28, flint 13, flint-glass 14.

In these forms, the ingredients are simply ground together, and are therefore called 'raw glazes,' in distinction from such as have a portion of the materials first united by calcination into a frit, or incipient glass; by this practice, a more complete combination is effected, a thinner coating of glaze will suffice, and the ware in consequence is less liable to craze with change of temperature.

Fritted glaze.—Cornish granite 30, flint 16, red-lead 25, soda 12, borax 17. Mix, and calcine in the easiest part of the gloss-oven, in saggers lined with flint; then take of the frit 26, Cornish granite 15, flint-glass 10, flint 9, white-lead 40. Grind the whole with a little oxide of cobalt, to increase the whiteness.

Drab-ware glaze.—Litharge 56, Cornish granite 20, flint 24.

Blue glaze.—Flint 40, borax 24, red-lead 16, Cornish granite 7, soda 5, oxide of tin 5, oxide of cobalt 5. Calcine it together, then grind with the addition of a little pearl-ash.

Green glaze.—Dissolve six pounds of sulphate of copper, and precipitate it with a solution of borax; to which add 10 quarts of white glaze.

Yellow glaze.—Colour a white glaze with king's yellow, to the depth of tint desired; or chromate of lead.

Black glaze.—Red-lead 74, flint 14, manganese 10, protoxide of iron 2.

When the goods have been dipped in the glazing mixture, they are dried, and placed in saggers, which are washed on the inside with a compound of glaze with lime and clay. Every piece is carefully placed so as not to touch another; otherwise, when the glaze melts, they would stick together. A variety of contrivances called cockspurs, triangles, stilts, pegs, &c. are adopted for the purpose of preventing adhesion; while the sagger is so filled that there may be no room lost. The glazing-oven is much smaller than the biscuit-oven, being about 13 feet in diameter and 15 feet high, and consumes seven tons of coals at one firing. When drawn from the oven, the ware is carried in baskets to the glossed warehouse, where it is again subjected to a close examination: every piece is sounded, and all the projections of glaze occasioned by the cockspurs, &c. are chipped off with steel chisels or files: it is then ready for sale.

We have thus far described the potter's art as it is practised in Staffordshire, where it is carried to a degree of perfection which has enabled the enterprising manufacturers of that district to secure a good recompense for their industry in all countries which are not closed against them by fiscal regulations. In addition to our own colonies, the United States of America, South America, the north of Europe, Italy, and the Levant are largely supplied from the Staffordshire potteries. [EARTHENWARE.]

PORCELAIN is a finer species of pottery, in which the ingredients are so contrived that they act chemically upon each other, and are brought to a state of vitrification; the fracture has a dense or greasy surface, like that of a flint stone, and is therefore not liable to be acted upon by acids. When the porcelain is coloured by metallic matter, it is called stone-ware; jasper and some drab-ware are of this description: but when it is perfectly free from colouring matter and is translucent, it is called China; of which there are two species, hard and soft china.

Hard china is made of silex, generally a fine sea-sand, kaolin, or china-clay, and felspar; sometimes the felspar is omitted, and a small quantity of selenite, or carbonate of barytes, or strontian, is used in its place.

Hard China body.—Kaolin 70, felspar 14, sand 12, selenite 4. The mixture is sometimes made in lime-water, and must be ground very fine at a mill.

When the paste is moulded into the desired forms, it is fired in the biscuit-oven at a very moderate heat; when taken out, it is very bibulous, and opake. In this state it is dipped in the glaze, which is felspar, ground fine, with the addition of a little alkali. Some prefer a mixture of felspar and broken china ground together. It is then submitted to a second fire of great intensity, which not only melts the glaze on the surface, but vitrifies the entire mass, which thus unites with the softer matter on the surface so completely, that the glaze does not form a coating of glass upon the body, but appears like the surface of a stone polished by a lapidary. This homogeneity prevents any crazing; but this process is one of much hazard, for if the fire is prolonged beyond the critical moment when the vitrification is effected, and the surface has become bright, the goods will melt, and sink in the saggers. Oriental, French, and German china are made on this principle; but the English have followed the safer practice which we shall next describe, and which the French manufacturers, aware of its advantages, are now adopting.

Soft or Tender China is made by firing the biscuit to its full vitrescence in the first oven, the shape of the articles being preserved, during their vitrescence, by being imbedded in flint-powder, &c.; and then glazing in the second oven at a lower degree of heat, so as not to endanger the melting of the goods. The union between the body and the glaze is however more complete than in earthenware, the glazing-fire being much more intense. Bones calcined and ground are largely used in the manufacture of English china, combined with aluminous and silicious earths in such proportions that they will vitrify together. This effect is promoted by the phosphoric acid of the bones, which at a high heat diffuses itself through all the materials, and unites them into a translucent enamel, which is less apt to sink and lose its form than the hard porcelain; it therefore may be made in larger ovens, and with less risk of loss to the potter.

English China body.—Bone 46, china clay 31, Cornish granite 23. For large pieces, such as dishes, &c., a little Dorset clay is added, to give more ductility in working and more stability in the fire; but when great purity of whiteness and transparency are wanted, a higher degree of vitrescence is obtained by fritting silex and bone together as the basis of the body.

Fritted China body.—Bone 55, Lynn sand 27, potash 2, calcined together; then ground fine, with china clay 18.

Glaze for China is harder than for earthenware: the following are very excellent. Cornish granite 25, soda 6, borax 3, nitre 1; mix, and frit in gloss-oven; then take frit 26, Cornish granite 26, white-lead 31, flint 7, carbonate of lime 7, oxide of tin 3. The whiteness is increased by the addition of a little oxide of cobalt.

Another China glaze.—Felspar 38, Lynn sand 24, carbonate of lime 11, borax 27: to be fritted. Then take frit 60, Cornish granite 20, white-lead 20.

The application of the glaze and mode of firing are the same as already described.

The decoration of china by enamel colours and gold affords employment to a great number of both sexes, some of whom attain great excellence in their beautiful art. The colours used are all prepared from metallic oxides, which are ground with fluxes, or fusible glasses, of various degrees of softness, suited to the peculiar colours with which they are used. The flux of most general application is made of red-lead 6, borax 4, flint 2. When painted, the goods are placed in the enamel-kiln, where the fluxed colours melt, and fasten to the glazed surface, forming coloured glasses. The judicious management of these mixtures requires much study, and is still susceptible of improvement by the aid of chemical science.

Blues are made from cobalt, varied by the addition of the oxides of zinc or tin. Phosphoric acid gives it a rich purple tint; alumine also varies its hue.

Green is from oxide of copper, melted with a soft flux, and ground; its tints are varied by adding blue or yellow or white enamel. Fine greens, which bear a fire that destroys a copper-green, are made from protoxide of chrome, varied with the addition of cobalt, lead, tin, or alumine.

Red.—Nitrate of iron, dichromate of lead, or muriate of manganese.

Pink.—Subchromate of tin.

Rose colour.—Gold and tin (precipitate of cassius) with a little silver.

Brown.—Chromate of iron or antimony, lead, and manganese.

Orange.—Antimony, tin, and iron.

Yellow.—Antimony, tin, and lead; also chromate of lead.

Black.—Oxide of platinum or iron, cobalt, nickel, and antimony.

White.—Arsenic and tin.

An infinite variety of tints may be obtained by a skilful combination of the above with suitable fluxes, the description of which in detail would exceed our limits. Few potters prepare their own colours; they are supplied by persons who devote themselves to that art.

Gold is applied to china in the state of amalgam ground fine in turpentine with a metallic flux. Thus, gold oxidized by being thrown in a melted state into aquafortis, 1 ounce; quicksilver 14 pennyweights, oxide of bismuth 1 pennyweight, chloride of silver 2 pennyweights. In the enamel-kiln, the bismuth and silver melt, and fix the gold to the china, without involving it so as to prevent its being burnished, which process is performed by females with agates.

POTTO. The *Yellow Maucauco* of Pennant, according to whom the last-named animal is *Viverra caudivolva* of Schreber, was called a *Potto* by its keepers. It had a prehensile tail, as also has the *Kinkajou* of Buffon, which Pennant describes as distinct from the *Yellow Maucauco*, though by form and manners a proper concomitant of it.

Pennant thus describes the *Kinkajou* after Buffon:—

Weesel with a short dusky nose: tongue of a vast length: small eyes, encircled with dusky: ears short and rounded, and placed very distant: the hairs short; on the head, upper part of the body, and the tail, the colours are yellow, grey, and black intermixed: the sides of the throat, and under side of the inside of the legs, of a lively yellow: the belly of a dirty white tinged with yellow: the toes separated: the claws crooked, white, guttered beneath. The length from head to tail two feet five (French); of the tail, one foot three: the tail is taper, covered with hairs, except beneath near the end, which is naked, and of a fine flesh-colour. It is extremely like the former (Yellow Maucauco); but larger in all its parts. Like the Yellow Maucauco it has a prehensile tail, and is naturally very good-natured: goes to sleep at approach of day; wakes towards night, and becomes very lively: makes use of its feet to catch at anything: has many of the actions of the monkey: eats like a squirrel, holding the food in its hands: has a variety of cries during night; one like the low barking of a dog; its plaintive note is cooing; its menacing, hissing; its angry, confused. Is very fond of sugar, and all sweet things: eats fruits and all kinds of vegetables: will fly at poultry, catch them under the wing, suck the blood, and leave them without tearing them: prefers a duck to a pullet; yet hates the water.

The *Kinkajous* which we have seen (and though two species have been described,[*] we believe that there is but one at present known) have not any part of the tail naked, and therefore, if Pennant's description be correct, his *Kinkajou* must be a different animal from that generally known under this name. They belong to the genus *Cercoleptes*, Ill., a South American form. Pennant names his *Kinkajou*, the *Mexican Weesel*.

Mr. Swainson treats the *Potto* and *Cercoleptes caudivolvus*, the name labelled on the three specimens of *Kinkajou* in the museum of the Zoological Society, as identical; and so do the French and Fischer. 'We have now,' says Mr. Swainson, 'only to consider the other animal above alluded to, namely, the Potto (*Cercoleptes caudivolvus*). This singular quadruped is a native of tropical America; and not only in its aspect, but in its general structure, has so much the appearance of a Lemur, that nearly all modern zoologists have placed it within or adjoining the confines of that family. Like them it has a very long hairy tail, which is moreover prehensile; it is a nocturnal animal with large eyes, and seems naturally to feed upon vegetables. It climbs like a Lemur, with agility; and Humboldt affirms it to be a great destroyer of wild bees'-nests, which it opens for the sake of feeding on the honey. On comparing the teeth of this animal with those of the Lemur, it will be perceived that there is a much greater resemblance between the two than there is between those of the Lemur and the Aye-Aye; although in the former comparison sufficient difference exists to exclude the *Potto* from the circle of the *Lemuridæ*. Baron Cuvier places the genus *Cercoleptes* close to the Badgers,[†] yet implying doubts as to this being its true situation; but his brother Frederick, with more judgment, looks on it as a passage from the *Lemurs* to the *Feræ*, although he thinks that its essential characters are different from either. In this opinion we perfectly coincide, because it is not only supported by facts of structure, but by other important considerations which bear upon the question. From *Cercoleptes* there is no difficulty in our passage to the Opossums through *Paradoxurus* and *Dasyurus*; so that the affinities between the orders of *Quadrumana* and *Feræ* are uninterrupted by anything known, and are found to be in union with that law of nature which invariably unites the typical and subtypical group.'

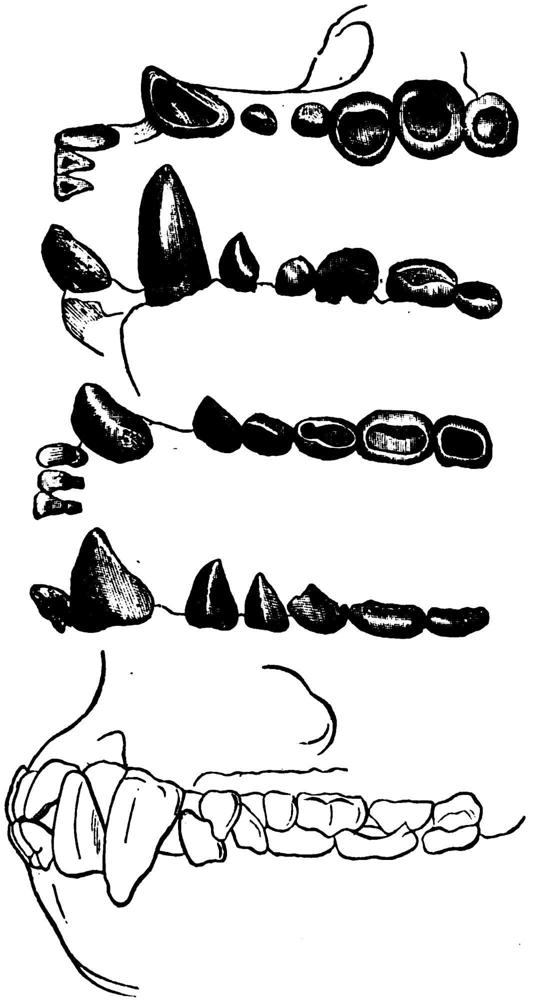
---

[*] 'Zool. Proc.,' 1836, p. 81.

[†] But next to the Coatis (*Nasua*, Storr).

Dental formula of *Cercoleptes*:—

Incisors $\frac{6}{6}$: canines $\frac{1-1}{1-1}$: molars $\frac{5-5}{5-5}$ = 36.



Teeth of Potto or Kinkajou, twice the natural size. (F. Cuv.)

Cercoleptes caudivolvus.

The *Kinkajou* is very mild in captivity, and climbs about the chairs, &c. in a room, if suffered to go at large. The tail does not seem to be very prehensile, nor does it appear to afford much assistance to the animal in climbing or descending. [Perodictus; Nycticebus.]

POULTON. [Lancashire.]

POULTRY, from the French *poulet*. The term includes all the domesticated birds reared for the table fowls, turkeys, geese, ducks, and Guinea fowls.

Fowls.—'The strong and ambulatorial feet of the gallinaceous birds adapted to the region where they chiefly resort for their food and the purposes of incubation; their toes and nails peculiarly formed for scratching up the grains and seeds which constitute the main part of their subsistence; their short wings and the weakness of their pectoral muscles, which cause the heaviness of their flight, a deficiency which is counterbalanced by the strength of those muscles of the thighs and legs that contribute to their powers of running; their gregarious, and, generally speaking, polygamous habits; the ease with which they are domesticated; their wholesome flesh; together with many striking peculiarities in their anatomy, serve equally to distinguish them.'*

Some foreign varieties have not even the rudiment of a tail, while others are distinguished by it. The game cock, which is probably a native of India, though for many centuries established in England, has an unusual length of spur, his natural weapon of combat. The flesh of this variety is delicately white and of the finest flavour, the plumage brilliant, and the form symmetrical; but from their pugnacious temper, there is great difficulty in rearing even those of the same brood; and for companionship with the general inmates of the fowl-yard they are very exceptionable for the same cause. So pugnacious however are the males of almost every variety, that they will spur even before their spurs are grown. For the natural history and peculiarities of the various varieties, we refer to the article Pheasant; we shall merely notice in this place the kinds suited to the purposes of the farmer.

The best breed of the gallinaceous fowls is the produce of the Dorking (Surrey) cock and the common dunghill fowl. This cross is larger and plumper, and more hardy than the pure Dorking, without losing delicacy of flavour or whiteness of flesh.

The characteristics of the pure Dorking are, that it is white-feathered, short-legged, and an excellent layer. The peculiarity of this established variety, which has frequently five claws perfectly articulated (with sometimes a sixth springing laterally from the fifth, but always imperfect), is well known. The crossing with the Sussex fowl has however greatly diminished the monstrosity in the Surrey pentadactylus variety. But though the true Dorking, which is white, is much esteemed, that colour is rare, and prized for the ornament of the poultry-yard: speckled colours are most generally seen with the higgler.

The Poland breed, which is black-feathered, with white topknots, lays well, and is highly desirable where the production of eggs for the table is the principal object; but they seldom sit, though they cannot be considered long-legged.

The Chittagong, or Malay, which is a very large Indian variety, is generally long-legged, with yellow body and coarse yellow flesh. Fanciers used to like them for their fine appearance and their large eggs; but as their long legs incapacitate them from steady sitting, they are not general favourites. One of our practical acquaintances recommends the male produce of the Poland and Chittagong as a good cross with the common dunghill hen, as their progeny will sit.

Parmentier thus describes the cock:—

'He is considered to have every requisite quality when he is of a good middling size; when he carries his head high; has a quick animated look, a strong and shrill voice, short bill, a fine red comb, shining as if varnished; wattles of a large size, and of the same colour as the comb; the breast broad; the wings strong; the plumage black, or of an obscure red; the thighs very muscular; the legs thick, and furnished with strong spurs; the claws rather bent, and sharply pointed. He ought also to be free in his motions, to crow frequently, and to scratch the ground often in search of worms, not so much for himself as to treat his hens. He ought withal to be brisk, spirited, ardent, and ready in caressing the hens; quick in defending them, attentive in soliciting them to eat, in keeping them together, and in assembling them at night.'†

Those who intend to rear fowls or any kind of poultry on a large scale, should have a distinct yard, perfectly sheltered, and with a warm aspect, well fenced, secure from thieves and vermin, and sufficiently inclined to be always dry, and supplied with sand or ashes for the cocks and hens to roll in, an operation necessary to disengage their feathers from vermin: running water should be especially provided; for the want of water, of which all poultry are fond, produces constipation of the bowels and inflammatory diseases; and for geese and ducks, bathing is an indispensable luxury. A contiguous field is also necessary for free exercise, as well as for the supply of grubs and grass to the geese. The fowl-house should be dry, well roofed, and fronting the east or south, and, if practicable, at the back of a stove or stables; warmth being conducive to health and laying, though extreme heat has the contrary effect. It should be furnished with two small lattice windows, that can be opened or shut at pleasure, at opposite ends, for ventilation, which is frequently necessary; and the perches should be so arranged, that one row of roosting fowls should not be directly above another.

---

* Vigors, 'Linnæan Transactions,' p. 402.

† Translated by Mr. Dickson, author of an excellent work on poultry.

M. Parmentier has shown* by what arrangement a house twenty feet long and twelve feet wide may be made to accommodate 150 hens at roost. The plan is simply this:—the first roosting-perch (rounded a little at the upper angles only, for gallinaceous fowls cannot keep a firm hold on perfectly cylindrical supporters) should be placed lengthways, and rest on tressels in each end wall, six feet from the front wall, and at a convenient height, which must depend on the elevation of the house from the floor, which should be formed of some well consolidated material that can be easily swept. Another perch should be fixed ladder-ways (*en échelon*) above this, but ten inches nearer to the back wall, and so on, until there are four of these perches like the steps of a ladder when properly inclined, but with a sufficient distance between the wall and the upper one to allow the poultry-maid to stand conveniently upon when she has occasion to examine the nests, which it is her duty to do every day at least once, and in the forenoon. The highest of these she can reach by standing on a stool or step-ladder. By this contrivance the hens, when desirous of reaching the nests, have no occasion to fly, but merely to pass from one stick to another. If the size and form of the house permit, a similar construction may be made on the opposite side, care being taken to leave an open space in the middle of the room, and a sufficiently wide passage for the attendant to pass along the walls. It is not at all required to have as many nests as hens, because they have not all occasion to occupy them at the same time; and besides, they are so far from having a repugnance to lay in a common receptacle, that the sight of an egg stimulates them to lay. It is however true that the most secluded and darkest nests are those which the hens prefer.

The nests, if built into the wall, are in tiers from the bottom to the top, the lowest being about three feet from the ground, and a foot square. If the laying-chambers consist of wooden boxes, they are usually furnished with a ledge, which is very convenient for the hens when rising.

But the best receptacles for the eggs are those of basket-work, as they are cool in summer, and can be easily removed and washed. They ought to be fastened not directly to the wall, as is generally the case, but to boards fixed in it by hooks, well clinched, and with a little roof to cover the rows of baskets. They will thus be isolated, to the great satisfaction of the hen, which delights in the absence of all disturbing influences when laying. All the ranges of nests should be placed checque-wise, in order that the inmates, when coming out, may not startle those immediately under: those designed for hatching should be near the ground (where instinct teaches the hen to choose her seat), and so arranged that the hens can easily enter them without disturbing the eggs.

Wheaten or rye straw is the most approved material for the bedding, being cooler than hay · the hens are sometimes so tortured by lice as to forsake their nests altogether, in an agony of restlessness. A Dorking housewife has assured us that she once lost an entire clutch, from having, as she believes, given a bed of hay-seeds to her sitting hen. The chicks were all glued to the shells, and thus destroyed, owing, as she thinks, to the high temperature occasioned by the fermenting seeds.

For all purposes two cocks in a good run are considered in the poultry counties contiguous to London as sufficient for twelve or fourteen hens, but in France they allow twenty mistresses to each cock, which no doubt is on account of the higher temperature there. In a confined yard, five hens are sufficient for one cock in our cold country, and a double set will not answer in very limited space. When there are two or more cocks, care should be taken not to have them of equal age or size, for in this case they are always jealous and quarrelsome; if one is decidedly ascendant, the other will never presume to dispute with him. It will be judicious also to avoid the introduction or changing of cocks in the breeding season, for the hens require constant intercourse with them, and several days frequently elapse before they become familiarised with a stranger. The best way is to bring in the new cock in the summer, either as a chick, or late in the year in the moulting season, when he will not take too much notice of the hens. As a general rule it would be well to have one a yearling and the other a year older. In the third year, the cock, who then becomes lazy and excessively jealous, should be killed.

In order to have the earliest chickens, hens should be induced to sit in October, which they may do if they have moulted early. By attention in this particular, chickens can be brought to the market at Christmas. But the object should be in general to set the eggs as soon as possible after Christmas, in order to have chickens with the forced asparagus in March, when they are worth in London from 7*s.* to 10*s.* a couple.

In selecting eggs for hatching, care should be taken that they are not at the utmost more than a month old, but their condition for hatching will greatly depend upon the temperature of the weather: vitality continues longest when the air is cool.

It has been asserted that the future sex of the bird is indicated by the shape of the egg; the round producing the female and the oblong the male. But this is contradicted, and, we believe, with sufficient reason, and it is impossible not only to foretell the sex, but even to ascertain whether the egg be fecundated. This however is certain, that if the air-bag (at the obtuse end), which has been mistaken for the germ, and the purpose of which is to oxygenate* the blood of the chick, be perforated even in the least conceivable degree, the generating power is lost altogether. Those eggs only which have been fecundated by the male are possessed of the vital principle. The number of eggs for a hen should not exceed sixteen, as she cannot impart the necessary warmth to more. It is by no means uncommon with experienced breeders to place two hens on the same day on their respective eggs, and then on the twenty-first day, when the broods are out, to give the maternal charge of both to one of the hens, removing the other to another set of eggs, which, if she be a steady setter, she will hatch as in the first instance. This however must be deemed a cruelty, though some hens would instinctively continue to sit until death. They would however become so attenuated by continued sitting, as to lose the power of communicating to the eggs the necessary degree of warmth. The practice of the Surrey breeders is to feed the hen on oats while sitting, as less stimulating than barley, which they give to the laying hens on account of this very quality.

Some fanciers use artificial mothers, which effect the purpose of imparting the necessary heat to the young chicks after birth, when there is no natural mother nor a trained capon to brood them. These artificial mothers—as used by Mr. Moubray, and described by him—are boxes lined throughout with wood. He recommends that a curtain of flannel should be suspended over the opening of the box for the exclusion of cold air.

Mr. Young states that 'five broods may at once be cherished under an artificial mother. This mother may be framed of a board 10 inches broad and 15 inches long, resting on two legs in front, two inches in height, and on two props behind, two inches also in height. The board must be perforated with many small gimlet-holes, for the escape of the heated air, and lined with lamb's skin dressed with the wool on, and the wooly side is to come in contact with the chickens. Over three of these mothers a wicker basket is to be placed, for the protection of the chickens, four feet long, two feet broad, and fourteen inches high, with a lid open, a wooden sliding bottom to draw out for cleaning, and a long narrow trough along the front, resting on two very low stools, for holding their food. Perches are to be fixed in the basket for the more advanced to roost on. A flannel curtain is to be placed in front, and at both ends of the mothers, for the chickens to run under, from which they soon learn to push outwards and inwards. These mothers, with the wicker baskets over them, are to be placed against a hot wall, at the back of the kitchen fire, or in any other warm situation where the heat shall not exceed 80 degrees of Fahrenheit.

---

* 'Dictionnaire d'Agriculture.'

* See the 'Domestic Habits of Birds,' in the 'Library of Entertaining Knowledge,' p. 115

'When the chickens are a week old, they are to be carried with the mother to a grass-plat for feeding, and kept warm by a tin-tube filled with hot water which will continue sufficiently warm for about three hours, when the hot water is to be renewed. Towards the evening the mothers are to be again placed against the hot wall.'

The artificial mother however is only a mechanical house for chicks already hatched; but the process of bringing the embryo of organised life in the egg through all the stages of the vital principle, until it becomes matured, by means of heated ovens, has been long and successfully practised in Egypt.

These ovens, which are constructed with bricks, are about nine feet high, with galleries extending through the whole length, and containing chambers into which a man can creep through a very contracted orifice for the purpose of depositing the eggs, which are laid, to the amount of several thousands, on mats or beds of flax over the brick floors. The heat is conveyed through fire-places, and the material of the slow fires, which are most effective, is the dung of cows or camels combined with straw. The fires are kept up for as many days (according to the temperature of the weather) as are sufficient to impart such a degree of heat as will continue to the expiration of the twenty-one days required for the hatching of chickens, care being taken to confine the warmth by closing up all the orifices communicating with the external air.[*] One hundred millions of chickens are said to be thus annually produced in Egypt.

M. Réaumur made various experiments in hatching with fermenting dung in hotbeds, but unsuccessfully; life was developed, but never matured; the chicks were in some cases even feathered, but long before the full time they lost vitality. He succeeded at length, 'after trials enough to wear out the most enduring patience,' with an oven free from the influence of the vapour exhaled from the dung, which in the previous experiments had been destructive of the embryo. He afterwards succeeded to a great degree by using a box or shelves over an oven, with due regard to uniformity of temperature. Several of the eggs in this latter case were hatched on the twentieth day, by which the usual course of nature was anticipated by one day. But though artificial hatching has long been practised with success in Egypt, it has not been found worth the expense and trouble in France, from the variableness of temperature there compared with that in the Delta, where, in the autumnal season, when the mamals (hatching-ovens) are used, it is remarkably steady and extremely warm.

Since the attempt to pursue the Oriental system has failed in France, there is no probability of its succeeding in the climate of Great Britain, but it by no means follows that success may not attend such management as will obviate the obstructions which arise from irregularities of temperature. The object was partially attained some years ago by means of steam, but uniformity of heat was not preserved, and consequently that experiment failed. It would appear however that the application of the Eccaleobion[†] machinery now exhibited in London by Mr. Bucknell, the inventor and proprietor, may be successful. Mr. Bucknell asserts that his eccaleobion possesses a perfect and absolute command over temperature from 300 degrees of Fahrenheit to that of cold water; so that any substance submitted to its influence shall uniformly be acted upon over its whole surface at any required intermediate degree within the above range, and such heat maintained unaltered, without trouble or difficulty, for any length of time, and that 'by means of this absolute and complete command over the temperature obtained by this machine, the impregnated egg of any bird, not stale, placed within its influence at the proper degree of warmth, is, at the expiration of its natural time, elicited into life, without the possibility of failure, which is sometimes the case with eggs subjected to the caprice of their natural parent.'

That chickens are thus hatched in considerable numbers is unquestionable, upwards of thirty thousand having been already brought into existence by this single eccaleobion machine, nor has any difficulty been found in the subsequent rearing of those chickens when proper yards and suitable temperature were provided, more than in the natural way; indeed in some respects less so, as the losses sustained in poultry by the sudden changes of the weather, and the influence of dampness in particular, and accidents from various causes, are very considerable. Supposing Mr. Bucknell's experiment to answer the purpose in every respect, the increase in the production of poultry might be rendered incalculably great by the adoption of his principle on a great scale, wherever the essentials of a dry soil, warmth, and proper buildings can at the same time be supplied.

'It must have struck even the most superficial observer, that the extraordinary fecundity of gallinaceous fowls is a wise and most benevolent dispensation of nature to provide the more abundantly food for man, as in those tribes of birds not suited for his table the female lays no more eggs than she can incubate. With respect therefore to domestic poultry, the most nutritious of all human food, this rich provision of a bounteous providence is for the first time available to Europe.'[*]

The eccaleobion machine, capable of containing 2000 eggs, resembles an oblong box, nine feet in length, three feet in breadth, and the same in height. It has no connection with the walls, against which it is placed on the table on which it stands; its regulating power is within.[†]

The following striking passage from Mr. Bucknell's work 'On Artificial Incubation,' above alluded to, will show the importance of this subject in its commercial and domestic bearings.

Mr. Bucknell observes (page 16), 'We call the Egyptians barbarous; the procuring however, by art and industry, an abundant supply of that necessary of life, good animal food, is no evidence of barbarism. If the population of the United Kingdom, which as respects Egypt is as twenty-four to two, were as well supplied with this artificial production as Egypt, it would require,—not ninety-two millions, but one thousand one hundred and four millions of poultry annually, for them to be as well fed in this respect as the uncivilised natives of Egypt. But how stands the account in this matter? Full one-third our population subsist almost entirely, or rather starve, upon potatoes alone; another third have, in addition to this edible, oaten or inferior wheaten bread, with one or two meals of fat pork, or the refuse of the shambles, per week; while a considerable majority of the remaining third seldom are able to procure an ample daily supply of good butcher's meat, or obtain the luxury of poultry from year to year.

'On the continent of Europe the population is still in a worse condition:—fish, soups made from herbs, a stuff called bread, made from every variety of grain, black, brown, hard, and sour, such as no Englishman could eat; olives, chestnuts, the pulpy saccharine fruits, roots, stalks and leaves, and not unfrequently the bark of trees; saw-dust, blubber, train-oil, with frogs and snails, make up and constitute a good part of the food of the greater portion of the inhabitants of Europe. There is no other cause for this than the excessive ignorance of its population.'

The contemplation of the progressive stages through which life is developed and matured in the egg, is highly interesting. The contents of the shells, of the species under immediate consideration, taken out and placed on a plate or a saucer on Mr. Bucknell's table, present the following appearances, according to the respective periods:—

On the third day, the embryo organization of the skull, brain, heart, and blood is perceptible by the aid of a magnifying-glass.

Fourth day. The pulsation of the heart is distinguishable by the naked eye.

Sixth day. The chief vessels and organs rudimentally formed; the pulsation and circulation of blood apparent.

Ninth day. Intestines and veins formed, and the deposition of flesh and bony substance commenced; the beak for the first time open.

Twelfth day. The feathers have protruded, the skull has become cartilaginous, and the first voluntary movement of the chick is made.

Fifteenth day. Organs, vessels, bones, feathers, closely approaching in appearance to the natural state.

Eighteenth day. Vital mechanism nearly developed, and the first sign of life heard from the piping chick.

Twenty-first day. The chick breaks the shell, and in two or three hours is quite active and lively.

[†] Ibid.

The exit of the chick from the shell is assuredly one of the most interesting processes of animated nature ever investigated by naturalists. It was supposed that the mother bird broke the shell; but M. Réaumur has long since detailed the processes, and we ourselves have witnessed the evolution of the chick in the eccaleobion by its own unassisted efforts. The French naturalist to whom we have just now referred thus explains some interesting facts:—'I have seen chicks continue at work for two days together. Some again work incessantly; others take rest at intervals, according to their physical strength. I have observed some, in consequence of their impatience to see the light, begin to break the shell a great deal too soon; for they ought, before they make their exit, to have within them provision enough to serve for twenty-four hours without taking food, and for this purpose the unconsumed portion of the yolk enters through the navel. The chick indeed which comes out of the shell before taking up all the yolk is certain to droop and die a few days after it is hatched. The help which I have occasionally tried to give to several of them towards their deliverance has afforded me an opportunity of observing those which had begun to break their shells before this was accomplished; and I have opened many eggs much fractured, in each of which the chick had as yet much of the yolk not absorbed. Besides, some chicks have greater obstacles to overcome than others, since all shells are not of an equal thickness nor of an equal consistence; and I think it probable that the same inequality takes place in the lining membrane. The shells of the eggs of birds of various species are of a thickness proportional to the strength of the chick that is obliged to break through them.'[*]

If the chick should be glued to the shell, as sometimes occurs, and is indicated by the faintness of its chip, and the non-enlargement of the fracture for some hours, it must be assisted (but not until the necessity is fully ascertained) in its liberation 'with a key, or some such instrument, and by cutting the membrane with the points of a pair of scissors. The operation, though painful to the chick, does not prove mortal; for it is no sooner freed than it exhibits as much vigour as any other chick of its age.'[†] But unless the chick, after a full day's effort, is found unable to chip the shell, from weakness or adhesion to its envelope, it is better not to assist it in its extrication; for in ninety-nine cases out of a hundred aid proves ineffectual, through the injury inflicted upon the delicate organization of the bird; or more probably the previous weakness or imperfection of the chick, which occasioned the necessity for assistance, also occasions its death at the moment of its birth, and would take place even if its disengagement were effected without any injury.

There is a caution to be observed in all cases regarding the eggs when the chicks are on the verge of maturity: they should not be stirred when within two days of the evolvement of the chicks. If any circumstances render it absolutely necessary to do so, care should be taken to place them with the broad end inclining upwards, as the beak of the chick is then in its proper position; and if this be reversed, the chick becomes unable to chip the shell, and must therefore die.

Chickens should be fed the day after their birth with crumbs of bread soaked in milk or with the yolk of an egg boiled hard, and they will quickly learn to eat curds, grits, and barley-meal and milk: if not designed for immediate use, they should soon get raw corn, and occasionally alteratives of green food, such as bruised leeks, nettles, lettuces, &c. For the first week they should be confined to the house altogether; after that time they may be let out for a short time in the sun, and gradually habituated to the weather. To render the hen which has already discharged her duty still more productive to her owner, she is frequently confined to a coop, called in Surrey a *rip*, for some weeks after the chicks have seen the light. Her offspring during this time pass freely through the prison bars, returning at her call or on occasions of alarm to the maternal wings, and then hopping out again to the inexpressible misery of their imprisoned mother, who is kept in this state of confinement until she becomes indifferent to the chickens and disposed to lay again.

The courage of the hen in defence of her offspring has been a common theme of admiration; the force of her maternal solicitude effects the most surprising change in her disposition and temper. Before she attained her matronly character, she was greedy, and always searching for food, fond of gadding about, and timid in the extreme. Now she becomes generous, self-denying, and intrepid; she assumes the fiery temper of the cock, and becomes a virago in defence of her helpless brood. An anecdote is told by White, in his 'Natural History of Selborne,' of the punishment inflicted by some hens upon a hawk which had at different times killed their chickens. By some means this hawk was caught, and the owner gave him up to the tender mercies of the bereaved mothers. In his own words, 'Resentment suggested the laws of retaliation. He clipped the hawk's wings, cut off his talons, and fixing a cork on his bill, threw him down among the brood hens. Imagination cannot paint the scene that ensued; the expressions that fear, rage, and revenge inspired were new, or at least such as had been unnoticed before. The exasperated matrons upbraided, they execrated, they insulted, they triumphed. In a word, they never desisted from buffeting their adversary till they had torn him in a hundred pieces.'

The same writer calls attention to the language of the fowl, from a pleased twittering to a scream. A laying pullet utters a complacent soft note, but when she has been delivered of an egg, her cackle of delight and importance is loud enough to excite the sympathetic voices of all her companions; when her chickens are hatched, she has a different language, which is intelligible to her little ones. The crested cock has various notes; his tone and language, for such it is in effect, as he calls his favourites to partake of the food which he gallantly scrapes for them, is of a very peculiar kind, and very different from his ordinary voice that is so familiar to us.

Poultry are the better for high feeding from the very shell, and on this account the heaviest corn is often far cheaper for them in the end than tailings, as regards the flesh, or the size and substantial goodness of the eggs. Young chickens may be put up for feeding as soon as the hen has ceased to regard them, and before they lose their first good condition. When chickens are wanted for domestic purposes, they are often left at liberty in the farm-yard, and if they have plenty of good food, they will be in the most healthful state for the table, and rich and juicy in flavour. Mr. Moubray ascertained that pullets hatched in March, if constantly high fed, laid eggs abundantly in the autumn; and if killed in the February or March following, were so excessively fat from the run of the yard as to open more like Michaelmas geese than chickens. Experienced poulterers will fatten fowls in two or three weeks with the aid of grease, which gives a luscious, but, in our judgment, a very disagreeable flavour to the flesh, which, though not actually diseased, is very inferior to that of the fowl fed at large in the common way at the barn-door.

The practice of cramming poultry by the hand is quite common. A machine for this purpose is used in France, by which one man can cram fifty birds in half an hour. It is somewhat on the principle of a forcing-pump. The throats of the birds are held open by the operator until they are gorged through a pipe, which conveys the food from a reservoir below placed on a stool. In fifteen days, fowls are said to attain the highest state of fatness and flavour by this feeding. In addition to the ordinary paste of barley-meal or meal made into little balls with milk, the dried seeds and leaves of nettles have been recommended by the continental poulterers, some of whom give a little henbane-seed to induce sleep, while others put out the eyes of the prisoners as the most effectual way of keeping them in a state of darkness, which is considered essential to their becoming rapidly fat; and under the pretext of relieving them from the irritation of vermin, they pluck the feathers from their heads, bellies, and wings. While fowls are thus preparing for the knife, though their bodies are closely confined, their hinder parts are free for evacuation and cleanliness, and their heads are at liberty to take in fresh supplies of nutriment.

The practice of making capons (emasculating the males) is practised a little in some of the English counties, and very much in France, where the females are also rendered incapable of breeding, and termed in their unsexed condition *poulardes*, in order to give them the tendency to fatten. An incision is made near the parts, and through this the finger is introduced to take hold of and bring away the genitals, but so carefully as not to injure the intestines; the wound is then

[*] 'Domestic Habits of Birds.' *Library of Entertaining Knowledge.*

[†] Ibid.

stitched up and rubbed with oil or grease; and the comb (which appears to be an unnecessary and gratuitous pain and insult to the sufferer) is often cut off. The females are treated much in the same way, when they do not promise well for laying or when they have ceased to be fertile; they are deprived of the ovarium. The subsequent treatment is similar to that in the former case. Care is taken to give them good food for three or four days, and during that time to keep them in a place of moderate temperature, to avoid the danger of gangrene, which, considering the time of the year—midsummer, when the operation is usually performed—is a very probable consequence. Pullets of the largest breed are selected for the purpose, as they yield the greatest weight to the poulterer; and if employed in hatching, cover the greatest number of eggs.

Cuvier states that the capon may be taught to hatch eggs and to act the part of a good nurse, with a little bell round his neck to supply the want of a good voice. He asserts that the natural courage and energy of this bird are not abated by the alteration of his condition, in which his audacity enables him to impose on the cocks and hens, so that they allow him to strut about with his former gait of consequential importance and to fulfil his duties without interference or molestation. This seems incredible, as a bold and haughty spirit under such circumstances is unnatural in the extreme. The pallidness of his head and the diminutiveness of his comb and gills indicate the contrary disposition, and he is so despised by the other fowls that they will hardly condescend to roost with him.

Mr. Young, in his 'Report of the County of Sussex,' says that much art and attention are requisite to make capons, and that the Sussex breed are too long in the body for success in the operation, by which many are lost. A perfectly fat capon will weigh from seven to ten pounds.

As soon as fowls are rendered sufficiently fat, they should be killed, or they will lose flesh and become unhealthy. The most humane and expeditious mode of putting them to death is by a smart blow with a blunt-edged stick, such as a child's bat, at the back of the neck. Higglers break the vertebræ of the neck by a sudden twist, and never bleed fowls, as this mode of dispatching them dries up the juices of the flesh. They bleed turkeys and geese however, after a stunning blow in the neck, not by cutting the throat, but by an incision in the upper part of the mouth.

Store fowls will feed well upon the tailings of corn, potatoes, and insects, and require little attention except when laying, during which time the food for the hens should be abundant, and their roosting-places dry and warm.

The diseases of all poultry principally arise from cold and moisture. Rheumatism decidedly arises from this cause. During or after moulting in a wet season, fowls frequently become diseased, as is evident from their drooping appearance, swelled and watery eyes, and the dropsical affections of the legs. Severe laying also sometimes causes emaciation and illness, which give way to a more healthy condition after the moulting season, if they have good food and dry weather.

Chickens are very subject, in wet or variable weather, to a disease called the chip, which appears in about a fortnight after their birth, when they are changing their feathers. Warmth and sunshine are the only restoratives within our knowledge.

The roup is properly an imposthume upon the rump, which is cured or relieved by opening, squeezing, and bathing with warm water. Mr. Moubray however, who is a good practical authority, states that the roup is a general term for all diseases, though it is chiefly applied to catarrh, which is indicated by watery eyes and running at the nostrils. This last disease resembles glanders in horses, and is infectious, and generally fatal. As all these diseases originate in moisture, dryness and warmth are the best counteracting influences. The nostrils should be washed with soap and water, and the eyes with milk and water. Mr. Moubray recommends a pepper-corn in dough at first, to impart warmth, and afterwards calomel three times a week as a finish to he cure.

We have had the trachea of a chicken dying of the gapes (which is the incipient stage of roup) cut and opened, and have taken out narrow worms, about half an inch in length, which lay imbedded in a serous fluid. A medical gentleman, now in the county of Kent, has frequently cured fowls of the same disease by putting the upper part of a feather, stripped for the purpose, down the trachea, turning it round, and thus bringing up the worm, which he thinks is the sole cause of the disease. It may however be the effect of the malady, as is the opinion of many.

The pip, which the same individual considers analogous to the thrush in the human kind (and which is probably a modification of roup), he cures, not by scraping roughly, but by an application of powdered borax dissolved in tincture of myrrh and water, and rubbed on the tongue with a camel-hair brush two or three times a day. This at the same time assists the bowels. The flux is not uncommon. Solid corn is the most certain remedy for this disease. Taken at the commencement, it is rarely serious, but if once established in the constitution, it becomes incurable, and, according to some, contagious. For constipation, bran or pollard, with milk, beet leaves, and lettuces, afford a certain cure.

Much of the foregoing matter applies to the rearing and management of all poultry. The succeeding observations will be brief.

*Turkeys.**—The greatest weight to which our domesticated turkey can be made to attain is 30lbs., and a turkey of even half this weight is 'a dainty dish.'

'The varied plumage of the bird in the domesticated state is well known to every one; and in no species is that sure mark of subjection to man more strongly seen. Every gradation of colour, from its original bronze, passing into buff, and in many instances into pure white, may be observed in these strutting denizens of our farmyards.' (*New Monthly Magazine*, 'Recreations in Natural History.') The bronze or copper-coloured is not considered hardy, nor often reared, and the varieties may be stated to be only two-fold, the dark-coloured and the light.

The dark-coloured birds are most prized for size and hardihood. Notwithstanding the great price which may be obtained for turkeys in London when fat, the finest young birds may be purchased in Ireland, fit for cramming, in September and October, from 4*s.* to 5*s.* a couple, and the light-coloured and smaller ones frequently from 2*s.* 6*d.* to 3*s.* 6*d.* a couple.

Turkeys, though extremely delicate in their infancy, become very hardy, and, if permitted, will roost on the highest trees, in the cold dry nights of winter, without suffering injury. The hen, which lays many eggs early in spring, sits thirty days, and covers from twelve to fifteen eggs. It is unnecessary for the turkey cock, as is the case with gallinaceous fowl, to be in constant intercourse with the hen during her period of laying. Two visits from him in that season are sufficient to impregnate all the eggs. She is a very steady sitter, and must be removed to her food and supplied with water, for she would never leave her nest. She wants the alertness and courage and sagacity of the common hen, and might be called a fool with much more propriety than the goose, which is an intelligent bird. The turkey hen is incapable of teaching her young ones how to pick up their food, on which account a poultry-maid should always attend them until they are reared.

'The author of "Tabella Cibaria" proves it upon the bird that it is "so stupid or timorous that if you balance a bit of straw on his head, or draw a line of chalk on the ground from his beak, he fancies himself loaded, or so bound that he will remain in the same position till hunger forces him to move. We made the experiment." We never did; but we doubt it not, though we cannot accept it as proof of stupidity. How much wit may be necessary to balance a straw may be doubtful; but gallant chanticleer has never been charged either with fear or folly, and yet you have only to take him from his perch, place him on the table by candle-light, hold his beak down to the table, and draw a line with chalk from it, so as to catch his eye, and there the bird will remain spell-bound, till a bystander, rubbing out the line, or diverting his attention from it, breaks the charm. Many a fowl have we fascinated in our boyish days.'†

On account of the constitutional delicacy of this bird, the hatching should not be commenced too early in the spring, and when the chicks are hatched they should be guarded from the extremes of heat and cold for some weeks. Rain is almost always fatal to them in their early stage. Curd, boiled eggs, and barley or oat meal, kneaded with milk (or water, in case milk should produce looseness), potatoes, nettles, parsley, Swedish turnips, with chopped beet-leaves, after a little time, is their proper food. As they retain so much of their original wild nature as to stray a considerable distance, if permitted, the hen should be tied or cooped for at least six weeks, when the chicks will be hardy enough to follow her about, under the vigilant eye however of the poultry-maid, who should beware of their being caught by a shower.

---

* For a most lively and interesting account of this bird, we would refer the reader to 'Ornithological Biography,' by an American, London, 1831.

† Ibid.

They are soon familiarised to the society of fowls in the poultry or farm yard. Without the advantage of the latter, it is an unprofitable speculation to rear any description of poultry on a large scale; but where a farmer's yard presents facilities, the economy of having all those kinds to which the soil and climate are suitable, is considerable. The only caution with regard to turkeys, where gallinaceous birds are numerous, is to have separate houses for them at night. These should be very lofty and well ventilated. They may be altogether open to the air in front, the doors being of trellis-work. Fowls (which are equally unsocial with the capons of their own kind) have a strong disinclination to roost with them

When well grown, turkeys supply themselves in their ramblings so far as to require food only when leaving their house in the morning and returning at night. The chances of rearing a second brood are not so great as to render it expedient to make the trial.

After six months turkeys may be crammed like fowls, but they require a much longer period to render them fully fat. Those great birds which are sent to the London market about Christmas, principally from Norfolk, frequently weighing from twenty to twenty-five pounds, are usually cocks from the preceding year.

Great numbers of turkeys are reared in Ireland, where the climate is congenial to their nature, and no doubt the housewives of that country will improve in the art of fattening them, from the facilities with which poultry may now be brought to the great English markets.

Guinea Fowl.—This bird, which is not much larger than the common barn-door fowl, is of beautiful form and plumage, and though not a source of profit to the peasant who rears poultry for immediate sale, is usually kept where there is proper accommodation, as much on account of the excellence and abundance of the eggs (which, though small, are well-flavoured) as for the sake of the flesh, which is prized in the London markets when the season of pheasant-eating ceases. The number of hens allowed to the male is about the same as among the gallinaceous family. The cock, little distinguished in appearance from the female, is an attentive and affectionate mate, and even obtrusively so to his favourites, whom he will attend to the nest, and remain with until they have laid their eggs.

Retaining some of their original wildness, Guinea fowl dislike the confinement of a house. For the purpose of laying, they prefer shrubberies, clover-meadows, or corn-fields, in which they will deposit their eggs, unless closely watched. The Guinea hen is fruitful during the entire summer, but not earlier than May. On this account and the difficulty of rearing a late brood, it is more beneficial to keep her entirely for laying, and to put the earlier eggs under a common hen or capon, which will cover from twenty to twenty-five, than to encourage the incubation of the natural parent, which is moreover indisposed to it, especially if under cover. If left to her instinct, this bird would at a late season, in the open air, sit for the natural period, which is twenty-eight or twenty-nine days.

The cock having the same dislike to incubation which characterises the male of pea-fowl, will destroy the eggs if he can discover them. Though the shell is remarkably hard, the chicks break through it at the proper moment, and are soon after as vigorous and ready to eat as the young of any other tribe of poultry.

The loud cry of these birds is not agreeable, but, like the scream of the pea-fowl, it announces with certainty an approaching change of weather. The hen utters a cry when she desires to roost, to call in her companions, to summon assistance, or to give notice of any of those alarms which her sensibilities cause her to express with such energy of voice, and in all which cases she is sure of receiving a ready sympathy.

The same food which is suited to the young of gallinaceous fowls and turkeys is good for the chicks of this kind; but as they are not often destined to the coops for fattening, a good deal of garden or field green-food may be combined with their grits, &c. after the first month. They have a great relish for insects of every kind, and thrive upon them as well as upon hemp-seed. When designed for the table, they ought to be killed at an early age, at which time the flesh is more juicy than that of other poultry of the same age, and very like that of the pheasant, though when old it becomes exceedingly tough. [PAVONIDÆ.]

Ducks.—The white duck, being the largest of the common domesticated kinds, is perhaps the best for the poulterer, though it is not deemed so delicate in flavour as the dark-coloured, such as that bred from intermixture with the Rhone duck, which is also large. The Muscovy variety is said to be a good breeder. One drake is sufficient for five females. It is generally believed that the duck lays no more eggs than she can cover (from twelve to fifteen), but Mr. Moubray states that, if well fed, some ducks will lay a great number, and he gives an instance of one laying an egg every day for eighty-five days.

For a fortnight after their birth, ducklings should be kept from rushing into water, to which their instinct soon leads them; and with this view the mother is frequently confined (where there is any pond within her reach) to the *rip*, already described, which should be placed on a field of short grass with a flat dish of water near it. The ducklings waddle about in search of insects, and at the maternal call return to the coop. This restraint upon the liberty of the poor mother should be avoided if circumstances permit, for to protract her close confinement after more than four weeks sitting is a cruel restraint. It is very common to place duck-eggs under a hen, on account of her excellent qualities as a nurse.

Any kind of meal is good for ducklings at first, and this may soon be mixed with potatoes. The refuse of the kitchen will not only support but fatten them; but to have them quickly and highly fattened, they should have oatmeal made into paste. They will also devour any animal offal, and have no fastidiousness whatever. If allowed to follow a plough or attend on the gardener when his spade is at work, their greediness and activity in picking up worms are extreme; and for gobbling up snails and slugs and other such delicacies in the field or garden they are most useful, while they are at the same time putting themselves into high condition. Having no fastidiousness of appetite, they never require cramming, indeed they act as if they considered it their duty to get fat as quickly as possible, and therefore require no artificial aid.

In a poultry-yard the ducks and geese are frequently lodged on the lower floor of the fowl-houses, but it is better, if the locality will permit, to give them distinct chambers, particularly where a good pond (free from eels) is available; on the margin of this their huts may be placed with very trifling labour, and an invisible paling* all round the water, constructed at bottom on the principle of the cage-trap, so as to prevent the ingress of rats or weasels, while it affords them a ready outlet, renders this department of the poultry establishment complete, though far too expensive for common adoption.

'Many families in Bucks derive a comfortable living from breeding and rearing ducks, the greater part of which, the early ones at all events, are actually brought up by hand. The interior of the cottages of those who follow the occupation presents a very curious appearance to the stranger, being furnished with boxes, pens, &c., arranged round the walls for the protection of the tender charge of the good wife, whose whole time and attention are taken up with this branch of domestic economy.'†

Geese.—The proportion of females to the males is the same as in the duck tribe, and the period of incubation and the number of eggs that may be set correspond exactly. The goose lays in a mild spring very early, and on this account (but only with high corn-feeding in the previous winter, and stimulating food during the entire breeding season) two broods may be had in the same year. Unlike the peacock and the Guinea cock, the gander is not only indisposed to do any mischief to the nests, but is very attentive to the hatching birds, whom he vigilantly protects as he sits patiently by; nor is his protection, as he accompanies the young gulls in due course, less creditable to his paternal character. The goose is a very steady sitter, but usually rises often enough to drink and take sustenance, without its being necessary to remove her from her nest for the purpose.

The early treatment of the gulls or goslings is similar to that of ducklings. The mother should be penned up for some days upon dry grass, but neither too early nor very late in the day; beet leaves or other green food may be mixed even with the early diet, if immediate fattening be not the object.

---

* Such may be seen at the Zoological Garden in the Regent's Park, London.

† Moubray.

Green geese are brought very early to the London market, and are worth at first from 8*s.* to 12*s.* each: they can be made quite fat with oat-meal and peas, and skimmed milk or butter-milk, when from four to six months old: many prefer oats alone.

The management of them in the vicinity of London is thus detailed in a communication to Mr. Moubray:—

'Cleanliness, punctuality, and regularity prevail; the business is conducted, as it were, by machinery, rivalling the vibrations of the pendulum in uniformity of movement. The grand object of preparing, not geese only, but poultry in general, for market, in as short a time as possible, is effected solely by paying unremitting attention to their wants; in keeping them thoroughly clean; in supplying them with proper food (dry, soft, and green), water, exercise ground, &c. On arriving at the feeders, they are classed according to condition, &c.: they soon become reconciled to their new abode and to each other. They are fed three times a day; and it is truly astonishing how soon they acquire the knowledge of the precise time; marching from the exercise-ground to the pens like soldiers in close column. Goslings, or young geese, come to hand generally about the month of March, after which a regular and constant supply arrives weekly throughout the season. At first they are fed on soft meat, consisting of prime barley or oat meal, afterwards on dry corn. An idea prevails with many that any sort of corn will do for poultry: this is a grand mistake. Those who feed largely know better, and invariably make it a rule to buy the best. The Messrs. Boyce of Stratford, whose pens are capable of holding the extraordinary number of four thousand geese, independent of ducks, turkeys, &c., consume twenty coombs of oats daily, exclusive of other food.'

But though green geese bring an enormous price in the spring, if thoroughly fat, farmers generally find it more profitable to feed goslings on the stubbles, where they supply themselves with the best food without cost, and become sufficiently fat at Michaelmas, when antient custom renders them a favourite dish.

> 'At Michaelmas by right divine,
> Geese are ordained to bleed at Michael's shrine.'

In the neighbourhood of the extensive commons in England great numbers of geese are kept.

> 'Nought is useless made; on the barren heath
> The shepherd tends his flock, that daily crop
> Their verdant dinner from the mossy turf
> Sufficient; after them the cackling goose,
> Close grazer, finds wherewith to ease her want.'
>
> Phillips's 'Cyder.'

But from the system pursued by the monopolising farmers of turning large flocks of sheep to consume the growing blade, the poor geese have short commons indeed, and gain little except air and exercise by their ramblings. The cottagers however supply them with the refuse of their gardens, and the goslings, when the harvest comes in, are bought up by the farmers, and fattened on their stubbles.

Though young geese are subject to a disease called the cramp, the greater number of those which die in summer are destroyed by starvation, and the change from corn, and other nutritive food, to the miserable herbage which the fields and commons yield; and this constitutes their chief diet until the harvest season. Cold and wet weather are often fatal to them in the earlier months, if they be neglected. Much mortality also prevails amongst grown geese, wherever the horrible system of plucking them alive prevails, as in Lincolnshire and in Ireland.* It is generally urged in excuse for this barbarity, that feathers are most elastic and valuable before the period of moulting, and that geese have been thus treated ever since feather-beds came into fashion. The offence carries some punishment with it; for it renders the flesh very tough, and in many respects deteriorates the value of a bird, if it does not destroy it altogether; but the immediate gain from the feathers counterbalances this and every humane consideration.

The cramming system is practised in France, when the object is to render the liver unnaturally enlarged by disease, with circumstances of great cruelty. We do not intend to give any information upon practices which we cannot recommend, and which we strongly condemn.

Eggs.—The most certain way of preserving eggs fresh is by greasing them with some unctuous matter, or immersing them in a strong solution of lime. In packing, they should be laid on end; for otherwise the yolks, preserving their centre of gravity, fall to the lowest side, and by adhesion to it become tainted sooner than if they were suspended in the centre.

The only management, besides warmth and high feeding, by which a perpetual succession of eggs can be obtained in winter, is by having pullets and hens of different ages, which, moulting at different periods, are not all incapacitated from laying contemporaneously.

POUND. [STANDARDS OF WEIGHT.]

POUSSIN, NICHOLAS, was born at Andely in Normandy, in 1594. He was descended of a noble family, but reduced in fortune by the part they had taken in the civil wars. Evincing an early inclination for drawing, he formed an acquaintance with an artist named Quentin Varin, and obtained his father's consent to adopt painting as a profession, of which Varin taught him the rudiments. At 18 he visited Paris, and received lessons from Ferdinand Elle, a Flemish portrait-painter, but in a few months quitted him, having already outstripped his capability of instruction. He now applied himself to the study of composition, in which he made great progress by an attentive consideration of some prints after Raffaelle and Giulio Romano, and careful copies from casts from the antique. Some of his earliest efforts in painting were the pictures in the church of the Capuchins at Blois, and some Bacchanalian subjects for the château of Chiverny. At Paris he became acquainted with Marino, the Italian poet, who invited him to Rome, but being at that time engaged on the picture of the Death of the Virgin, he was compelled to decline the invitation; in 1624 however he was enabled to undertake the journey. His friend received him with kindness, and introduced him to the notice of the cardinal Barberini, nephew of pope Urban VIII.; but that dignitary being sent on a legation to France and Spain, and Marino soon after dying, Poussin found himself deprived of the support that he expected in a foreign city, and without the means of subsistence other than by the exercise of his art. To supply his wants, he painted many pictures which he sold for scarcely more than the money they cost for canvas and colour, and two battle-pieces in particular only produced him fourteen crowns the pair. He formed an intimacy with Francis du Quesnoy, the sculptor, called Il Fiammingo, with whom he lodged, and together with that eminent man he studied and made models after the most celebrated statues and bas-reliefs. The works of Raffaelle were however the greatest attraction to Poussin, and he studied them with intense devotion.

On the return of the cardinal Barberini to Rome, he liberally patronised Poussin, who painted for him his celebrated picture of the Death of Germanicus, and the taking of Jerusalem by the emperor Titus. His patron also procured for him the commission to paint a large picture of the Martyrdom of St. Erasmus, for St. Peter's, which is now in the pontifical palace of Monte Cavello. These productions established his reputation, and recommended him to the friendship of the Cavaliere del Pozzo, for whom he painted his first series of the Seven Sacraments of the Church of Rome, which were afterwards brought to England, and are now in the possession of the Duke of Rutland, at Belvoir Castle, but one of them was unfortunately destroyed in the fire which occurred there in 1816. He afterwards painted another set of the Sacraments, executed in 1644 and 1647, with variations, for M. de Chantelou, which were among the principal attractions of the Orleans collection, and were purchased by the late Duke of Bridgewater for 4900 guineas, and now are in the collection of Lord Francis Egerton.

The celebrity which Poussin had now attained induced Louis XIII., in 1639, to desire his return to France, which took place in the following year, when he was appointed principal painter to the king, and had apartments assigned him in the Tuileries. He was commissioned to paint an altar-piece for the chapel of St. Germain-en-Laye, where he produced his admirable work of the Last Supper, and was engaged to decorate the gallery of the Louvre, for which he had prepared the designs and some of the cartoons, representing the Labours of Hercules, when the criticisms of his brother-artists excited his disgust, and determined him to depart again to Rome, to obtain leave to do which he feigned a desire to settle some private matters and to fetch his wife to France. He quitted that country in 1642, with a determination, which he adhered to, never to return. He resided in Rome, passing his time in diligent practice of his art, and in the strictest simplicity and privacy of living, until the year 1665, when he died, in the seventy-first year of his age.

---

* See Doyle's *Cyclopædia of Practical Husbandry*, page 395.

Speaking of the style of this eminent painter, Mr. Fuseli observes, 'Though Poussin abstracted the theory of his proportions from the antique, he is seldom uniform and pure in his style of design; ideal only in parts, and oftener so in female than in male characters, he supplies, like Pietro Testa, antique heads and torsos with limbs and extremities transcribed from the model. As a colourist he was extremely unequal. Into the Deluge, and the Plague of the Philistines, he transfused the very hues of the elements whose ravages he represented, whilst numbers of his other pictures are deformed by crudity and patches. The excellence of Poussin in landscape is universally allowed, and when it is the chief object of his picture, precludes all censure; but considered as the scene or background of an historical subject, the care with which he executed it, the predilection which he had for it, often made him give it an importance which it ought not to have; it divides our attention, and from an accessory, becomes a principal part.'

Poussin was a profound admirer of the antique, and his mind seems to have been strongly imbued with a veneration for classic forms. No painter amongst the moderns appears to have so greatly excited his admiration as Raffaelle. In the sublimity of his conceptions, he is in some instances little inferior to that great master, nor is he much less so in the beauty of his female forms, the grace and dignity of his attitudes, and his admirable expression of the passions. His compositions evidence an intimate acquaintance with the true principles of art. They are simple, grand, and impressive; whilst his draperies are disposed with classical grace and his costumes rigidly correct.

(Bryan's *Dictionary*; 'Note,' by Fuseli, to Pilkington's *Dictionary*; *Biographie Universelle*.)

POUSSIN, GASPAR, was born at Rome, in 1613. His family was originally French, and bore the name of Dughet, but his father had settled at Rome, and Nicholas Poussin having married his sister, he acquired the appellation of Gaspar Poussin. He studied under his brother-in-law, by whose advice he adopted landscape painting, and soon became one of the most celebrated practitioners in that branch of art. His early works are somewhat hard, but a contemplation of the pictures of Claude induced him to adopt a more mellow effect. He is said to have acquired such a facility of execution, that he could paint a large landscape in a single day. His pictures represent the most interesting prospects in the vicinity of Rome, Tivoli, and Frascati. His touch is firm and vigorous, and the foliage of each tree and plant bears the peculiar character of its species. The massing of his pictures is simple and grand, and the management of the chiaroscuro very fine. Every variety of effect may be discovered in his works, from the utmost serenity to the most terrific convulsions of nature, and each appropriately treated. His pictures are sometimes embellished with figures by Nicholas Poussin, usually representing some subject of history or fable. There are a few slight but masterly etchings by this great artist; they are a set of four circular landscapes, and a set of four landscapes lengthways. He died at Rome, in 1675. He had a brother John Dughet, called also Poussin, born in Rome about 1614, who was an engraver, but of little note. (Bryan's *Dictionary*; *Biographie Universelle*.)

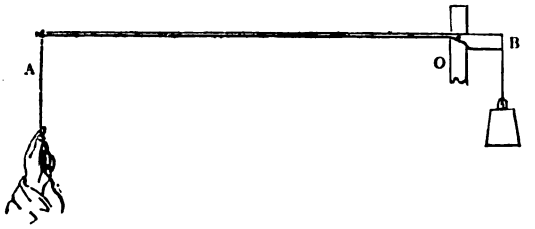
POWER (Mechanics). The present article is not intended to enter deeply into the subject, but only to remove various fallacies connected with the use of the word power, which frequently perplex and confuse those who attempt to study mechanics without the aid of mathematics.

The word power has obtained a technical meaning which seems to be almost peculiar to the popular treatises. From among the numerous combinations which occur in machinery, the lever, inclined plane, wheel and axle, pulley, and screw have been selected, and named mechanical powers. Some have treated these as all different principles; some have asserted that they are reducible to the lever and inclined plane, others to the lever only: but it is generally asserted that all mechanical contrivance is reducible to one or other of these. To which of them the very powerful machine (in its way) which men call a cannon is to be referred we do not know, not seeing any great likeness in it either to a lever, inclined plane, wheel and axle, pulley, or screw. Again, the notions of the theories of these powers are as various as those of their arrangement: some say that all are creators of power, some that all are powers except the simple pulley, some that none are powers, some that they are losses of power. Those who deny that any of the adaptations above mentioned give power, look for their meaning of the word in the action of what are thence called agents, as in the muscular strength of men and animals, the force of wind, the fall of water, the expansion of steam or explosive gases, &c. Admitting that all these agents are well entitled to the name of powers, it is nevertheless difficult to refuse that name to a machine. Watch the effect of a large crane in unloading a vessel, compare it with what the same men could do by their unaided (or rather, unadapted) strength in the same time, and it will be impossible to deny that the machine gives power.

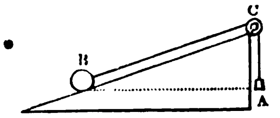
The cause of all this confusion and diversity of opinion as to the way of stating facts which every one knows, arises from the word power being taken in two different senses, that which is true of one of its meanings being untrue of another. In the first sense, power is gained whenever any thing is done quicker or better at the same expense, or in as effective a manner at less expense; whenever the advantage gained, or the disadvantage avoided, is worth more than the trouble and cost of the means employed. In the second sense, power is gained when a new adaptation is introduced, by which an existing agent is made apparently stronger. To find different phrases for these different things, let us say that power in the first sense means that which produces beneficial effect, and that power in the second sense means that which produces mechanical advantage: these last words have been often used by writers in the same sense as the technical word power.

Beneficial effect may be produced in various ways, without mechanical advantage, but the benefit, as far as it is of a physical character, will generally be found to consist in a saving of useless labour. Thus, in the division of labour, than which nothing produces more of beneficial effect, there is not only the moral benefit, namely, the making the human agent fitter for his work by giving him a more limited range of occupations, but the actual saving of the labour of laying down one tool and taking up another. Again, when loaded carriages are dismissed down an inclined plane and made to draw up the empty ones, there is no gain in a mechanical point of view, for the momentum which is gained by the empty carriages is lost by the loaded ones; but the momentum lost by the loaded carriages is no loss, since there is no use in their delivering their contents with a great velocity, while the momentum abstracted is applied to a beneficial purpose. Thirdly, a simple pulley gives no mechanical advantage whatever, since the weight on one side, when the pulley is at rest, must be equal to that on the other. If however we compare the effect of this machine in raising weights with the carriage of them up a ladder, we see at once a beneficial effect, amounting to a saving of the greater part of the labour. With a pulley, the labourer has not to carry himself up to the height required and down again. Fourthly, when the traces by which horses draw are inclined at a proper angle, a part of the drawing power is taken off, and applied in lifting the carriage off the road and lessening the friction, so that the diminished draught is better able to do the remaining work than if the whole draught were applied to the whole friction. Here is no gain of power in the mechanical sense, though the alteration is certainly a double gain (no matter how slight a one) of beneficial effect, for the carriage is more easily drawn and the road is less worn. Numberless instances might be cited in which real benefit is a consequence of mere adaptation, even without the production of what is called power in treatises on mechanics.

In treating of the second meaning of the word power, or its synonym, mechanical advantage, we must separately consider a machine just balanced, and one in which an additional force applied gives motion. Suppose a lever, one arm of which OA is ten times as long as the other OB, and suppose that the arms balance each other. A pull of one pound at A will then support (so it seems) ten pounds at B, for the first will certainly equilibrate the second, or prevent motion. Nevertheless, it is not true that one pound supports ten pounds; nor can one pound, by any contrivance whatsoever, be made to support more than one pound. In the case before us, A acts against one pound, but not one pound of B; it is A and B together, eleven pounds in all, which oppose a resistance of eleven pounds offered by the support or pivot O. The weight B is equivalent to two pressures, one downwards, at O, of eleven pounds, one upwards, at A, of one pound. The frame on which the pivot rests neutralises the first, the pull at A neutralises the second. To say that A supports B, would be an assertion like that of a person who should say that he had paid 11*l.* with 1*l.*, and should forget that he had borrowed 10*l.* elsewhere; and in the above system there is neither gain nor loss of force in any manner. When the weight B is lifted from the ground, and attached to the end of the lever, and when at the same moment the hand was applied at A, there is a pressure of eleven pounds applied to the earth at O. But all this pressure was first taken from the earth, ten pounds of it by the removal of the weight B, and the remaining pound by diminution of the weight of the person pulling; for a person who pulls downwards at a rope in such a manner as to supply the place of a pound weight at the end of the rope, lessens his weight by one pound.



In the preceding manner it may be shown that every machine in which A, the less, balances B, the greater, is a case of the following kind:—B is equivalent to certain forces, P, Q, R, &c., applied at various points of the system, and to C, equal and opposite to A. Imagine P, Q, R, &c. and C substituted for B, then P, Q, R, &c. are counterbalanced by the resistance of the parts of the machine, and C, and C only, is counterbalanced by A. It may also be shown that the whole pressure upon the earth is just what it would be if the machine were dismantled, and its parts, together with the weights, laid upon the ground.



Let us now consider the machine in motion. The paradox about power here is, that the smaller weight is made to lift the greater; for example, that a pressure, say of one pound, applied to the handle of a crane, lifts a weight of say twenty pounds. As long as no more precise mode of expression is employed, the paradox continues:—the smaller weight *does* lift the greater. To take the simplest case, suppose that the descent of a smaller weight causes the ascent of a greater, as in an inclined plane with a pulley. It is now obvious that before the larger weight B can rise through AC, the smaller weight A must fall through a length equal to BC. In any machine in which the hand, exerting a pressure of one pound, balances a weight of twenty pounds, the hand, when put in motion to raise the weight, will move twenty times as fast as the weight. It is then one pound moved through twenty feet, which is mechanically equivalent to twenty pounds moved through one foot, and the paradox disappears. It is usual to express this by saying that what is gained in power is lost in time; but instead of this axiom, which only indirectly expresses the truth, it is better to say that a less weight cannot cause the ascent of a greater through a given height, without descending through a height greater in the same proportion as that by which the greater weight exceeds the less. Perhaps the easiest mode of balancing the power applied and the work done is as follows:—Suppose one pound descending through four feet raises four pounds through one foot, we have then applied the descent of one pound through one foot four times, and produced the ascent of one pound through one foot four times. The only difference is, that in the applied power it is the same pound which moves over four different feet, while in the produced effect there are four different pounds moving over the same foot. The machine is nothing but an adaptation which enables the agent to effect the exchange just mentioned. And though the common notion that a machine gives power usually has reference to the substitution of greater weight with less velocity for a smaller weight with greater velocity, yet it frequently happens that the apparent power is gained by the contrary exchange, as in the common grinding-wheel and in the lathe. Frequently also the beneficial effect arises from a reservoir of power which is given out in small quantities, as in a clock or watch, in which the exertion of raising a weight or coiling a spring is expended in minute quantities over one or more days.

Without entering further into the preceding principle (for which, in its mathematical bearing, see Virtual Velocities), we will now touch upon some additional circumstances connected with the use of a machine, still confining ourselves to simple exposition of these circumstances, and avoiding mathematical explanation. Suppose a crane by which a man, with a certain amount of labour, raises five hundredweight through a height of ten feet, working all the while as if he were raising half a hundredweight, by a simple pulley, from the deck of a vessel to the wharf. If this five hundredweight were divided into ten portions of half a hundredweight each, and if each of these portions had a rope fastened to it, it would matter nothing, the manner of working being equally convenient in both cases, whether he raised the whole at once by the crane, or the ten portions in succession by their several ropes. This supposes that there is no friction in the parts of the crane, and that its wheels can be moved without any exertion when unloaded. Neither of these is true, for the friction of the loaded machine is considerable, and even the unloaded machine costs some exertion to set it and keep it in motion. So far then the balance is in favour of raising the ten subdivisions of the five hundredweight in succession; and we now see what those persons mean who say that a machine is a loss of power. But if we introduce the beneficial effect produced by the machine, we see that the subdivision of the weight is avoided, and that the labour thereby saved may be thousands or even millions of times that caused by the friction of the machine and the necessity of moving its wheels, &c. A little attention to such considerations as the preceding will prevent the reader, however unpractised in mechanical considerations, from being led away by accounts of perpetual motion [Motion] and of machines which are to work without power applied.

The muscular power of men and animals, the force of wind, the fall of water, the expansive power of steam, &c. are real powers, the explanations of which lie in the secrets of the laws of life, gravitation, and chemistry. A machine is an adaptation of material elements to one or more purposes, the life of which is one or other of the powers just mentioned. But nothing is more common than, in describing the wonderful effects of power and adaptation united, to lay the wonder on the wrong part. Thus we can imagine a person describing the progress of mechanics in the last century, by saying that 'lace is made by steam, and mines which would be covered with water but for the application of science, are cleared for the miners by machinery.' In the first instance the steam-power is but subordinate; horses or a water-mill might supply its place without any diminution of the extraordinary part, which is the adaptation of machinery to the performance of that which required so many and varied motions of the fingers. In the second instance, common pumps, or successions of them, would do as well as the machinery employed, if hands enough could be found to work them: the wonder is the introduction of labour to any amount by the help of steam. The vulgar notion is that steam, as steam, can adapt itself to anything, and that machinery, as machinery, can work.

POWER (Algebra). [Root.]

POWER OF ATTORNEY. [Letter of Attorney.]

POWERS (Law). [Uses.]

POWNALL, THOMAS, was born at Lincoln, in 1722. He went to America in 1753, and was elected governor of the colony of Massachusetts Bay in 1757. In 1759 he was appointed governor of New Jersey, and soon afterwards proceeded to South Carolina as governor and captain-general. Having solicited his recal, he returned to England in 1761. In 1768 he was elected a member of the House of Commons, and spoke frequently against the war with America. He retired to Bath in 1780, where he died in 1805.

Pownall was a fellow of the Royal Society, and of the Society of Antiquaries. He was the author of a few works, of many pamphlets, chiefly antiquarian and political, and of several papers in the 'Archæologia.' Among his more important works may be mentioned his 'Notices and Descriptions of the Antiquities of Provincia Romana of Gaul,' London, 1788, 4to.; and his 'Intellectual Physics, an Essay concerning the Nature of Being,' 1803, 4to. A full list of his productions is given in Watt's 'Bibliotheca Britannica.' (*Encyclopædia Americana; Biog. des Contemporains.*)

POYNING'S LAW. [IRELAND.]

POZZUO'LI, *Púteoli* (Ποτίολοι, Strabo), an antient town of Campania, situated on the eastern shore of the gulf of Baiæ, five miles west of Naples, from which it is separated by the hill of Posilipo, through which a tunnel was excavated in antient times. [POSILIPO.] Pozzuoli lies at the foot of the volcanic hill called La Solfatara, and on the western side of it is another volcanic hill called Monte Nuovo, which was thrown up in one night, in September, 1538, on the site of the Lucrine lake. [PHLEGRÆI CAMPI.] Pozzuoli was a colony of Cumæ, of which it was the port, and was then called Dicæarchia. It afterwards became allied to Rome, to which it remained faithful in the midst of the general defection of the towns of Campania during the second Punic war. Hannibal tried in vain to surprise it. (Livy, xxiv. 13.) A Roman colony (Civium Romanorum) was sent to Puteoli, after the close of the second Punic war, in B.C. 194. (Livy, xxxiv. 45.) The Romans gave it the name of Puteoli from 'putei,' the wells, or, as others say, from 'putor,' the stench of its springs, which are impregnated with sulphur. (Strabo, p. 245.) Puteoli was a flourishing place under the Romans, being resorted to by the wealthy for the sake of its situation and its mineral springs. It is now a decayed town, with about 10,000 inhabitants, and is a bishop's see. The air of Pozzuoli, and especially of the country around it, is considered unwholesome in the summer months. The remains of antiquity at Pozzuoli attract numerous travellers. The temple of Jupiter Serapis is now cleared of the rubbish which had encumbered it for ages; three columns are still standing, and the pedestals of others, and there is a handsome pavement of white marble. Near it is a number of cells and a bath, supposed to have been for the use of the priests. The amphitheatre is in great measure ruined and encumbered with rubbish and soil, but part of the walls and arches are cleared. There are also remaining several piers of the antient mole, which was built on arches like a bridge, so as to allow free ingress and egress to the sea, through the passages: this was done to prevent the accumulation of sand, which is apt to take place in those harbours which are confined by solid continuous moles. It was to the end of the mole of Pozzuoli that Caligula attached a floating bridge, which is said to have reached the opposite coast of Baiæ, a distance of about two miles in a straight line, though Suetonius calls it more than three. (Suetonius, *Caligula*, 19.) The cathedral is built on the ruins of an antient temple, the materials of which have been employed in its construction. There is also a subterraneous construction called the Labyrinth, or 'Cento Camerelle,' which appears to have been a water reservoir. [BAIÆ.]

In the country around Pozzuoli is found a kind of reddish earth called Pozzolana, which, being mixed with lime and water, forms an excellent cement, that becomes in time as hard as marble, even when immersed in the water of the sea. It is found also at the foot of Vesuvius, where it is of a greyish colour, but is equally good. (Vitruvius, *De Archit.*, 11, 6.) The old moles of Puteoli were made by throwing masses of this compound into the sea, and thus this open shore was furnished with a harbour capable of containing the largest trading ships. (Strabo, p. 245.)

POZZUO'LO. [NOVI.]

PRACTICE, a rule of arithmetic, appropriately so termed because it hardly contains any new principle, but depends for its application upon the memory and dexterity which the operator acquires from practice. Thus in the following simple question, 'How much do forty yards cost at eighteen pence a yard,' some arithmeticians (unpractised) might find it necessary to multiply 40 by 18 and divide the result by 12, for the number of shillings in the answer: but a practised arithmetician would immediately see that 18*d.* is a shilling and a half, so that 40 shillings must be allowed for the shilling, and 20 shillings for the half shilling, making altogether 60 shillings. More complicated examples may require greater subdivision, but the method of proceeding has been completely described in the preceding. Suppose for instance it is required to find the price of 253¼ yards at 2*l.* 13*s.* 7¾*d.* a yard. The application of the rule of practice is as follows:—

At 1*l.* pr. yd. 253¼ yds. cost	£253	5	0	
			2	
2*l.* is 2 × 1*l.* .	506	10	0	
10*s.* is ½ of 1*l.* .	126	12	6	
2*s.* is ⅕ of 10*s.* .	25	6	6	
1*s.* is ½ of 2*s.* .	12	13	3	
6*d.* is ½ of 1*s.* .	6	6	7½	
1½*d.* is ¼ of 6*d.* .	1	11	7¾	½
¼ is ⅙ of 1½*d.* .		5	3¼	¼
At 2*l.* 13*s.* 7¾*d.* pr. yd. 253¼ yds. cost	679	5	9½	¾

The process hardly needs more description than is given on the left; the only difficulty is the division of the price into portions each of which is a simple aliquot part of one of the preceding, and this difficulty is to be overcome by practice. It is also to be noticed that easy verifications often occur; thus in the last process but one, it can easily be verified that 253¼ farthings is 5*s.* 3¼*d.* ¼.

When both the factors which are to be multiplied contain complicated fractions, this rule can be easily applied by turning the money factor into pounds and decimals of a pound, as in INTEREST. Thus suppose it is required to find the price of 22 ton 17 cwt. 1 qr. 19 lb., at 13*l.* 16*s.* 4*d.* a ton, or 13·81667*l.* We have then

1 ton	costs	£13·81667
		22
22 ton	„	303·96674
10 cwt. is ½ of 1 ton		6·90833
5 cwt. is ½ of 10 cwt.		3·45417
2 cwt. is ⅕ of 10 cwt.		1·38167
1 qr. is ⅛ of 2 cwt.		·17271
14 lb. is ½ of 1 qr.		·08636
4 lb. is ⅐ of 1 qr.		·02467
1 lb. is ¼ of 4 lb.		·00617
22 ton 17 cwt. 1 qr. 19 lb.	cost	£316·00082

So that the proper answer is less than a farthing above 316*l.* The preceding process is much shorter than the application of the rule of three, and also than a kind of double rule of practice once in use, which is not given in modern works, and is not worth revival.

This method of practice is also a convenient way of reducing fractions of weights or measures to decimals. Thus if 17 cwt. 1 qr. 19 lb. is to be reduced to a decimal fraction of a ton, we have

1 cwt. is	·05	of a tou.
17 cwt. is	·85	. .
1 qr. is ¼ of 1 cwt. or	·0125	. .
14 lb. is ½ of 1 qr. or	·00625	. .
4 lb. is ⅐ of 1 qr. or	·0017857	. . .
1 lb. is ¼ of 4 lb. or	·0004464	. . .
17 cwt. 1 qr. 19 lb. is	·8709821	of a ton.

PRÆFECTUS URBI (prefect or warden of the city) was the title of a Roman magistrate. The office was said to have been instituted by Romulus (Tacit., *Annal.*, vi. 11) to supply the place of the kings in their absence from Rome. Within the walls of the city he was for a time invested with kingly power: he had the administration of justice, and on any sudden emergency he took such measures as he thought necessary; in short, he had the imperium in urbe. (Livy i. 59.) He was appointed from among the senators. (Dionys., ii. 12.) Whether on the return of the king he laid down his title with his office, is uncertain. During the time of the republic the præfectus urbi was appointed by the consuls or by the senate (Dionys., viii. 64), when the consuls were obliged to be absent from the city. In the early times of the republic he was generally a consular. During the time of his office he exercised in the city the power of the consuls (consulare munus usurpabat): he had the right to convoke the senate (Varro, *Ap. Gell.*, xiv. 7, comp. with xv. 8), and to hold the comitia (Liv., i. 60). But in the course of time the prefect of the city was superseded by the prætor urbanus, on which the former magistrate became merely a shadow (simulacrum) of what he had been, and was appointed while the consuls were absent from Rome for the purpose of celebrating the Feriæ Latinæ. This office, being of no importance, was often filled by young men, and Julius Cæsar even appointed several youths under age as prefects of the city. (Tacit., l. c., iv. 36; Dion Cass., xlix., p. 476.) This shadow of a magistrate seems to have continued to be appointed during the Feriæ Latinæ, even after Augustus had made a permanent præfectus urbi. (Suet., *Nero*, 7.) Augustus invested this new prefect with considerable power, gave him the superintendence of public works, roads, and aqueducts, of all things connected with the navigation of the river, and of the corn to be distributed among the people. (Suet., *Octav.*, 37; Tacit., l. c.; Dion Cass., lii., p. 547.) This præfectus urbi was generally taken from the consulars and the most distinguished men of the state. He was also invested with jurisdiction over slaves and turbulent citizens. He was thus something like a chief officer of the police; but his powers became gradually more and more extensive, so that almost all the powers formerly belonging to the office of prætor urbanus in the end were transferred to the præfectus urbi (*Dig.* i., t. 12; *De Off. Præf. Urbi*, comp. with Tacit., *Annal.*, xiv. 41); and from the beginning of the third century he not only exercised the inferior but also the criminal jurisdiction, and that not only in the city, but at the distance of one hundred miles from it. During the early period of the empire the prefect of the city seems always to have held his office for a number of years, but from the time of Valerian we find a new prefect almost every year. Respecting the titles by which he was addressed, see Brisson, *De Form.*, p. 296. At the time when Constantinople was raised to the rank of the second capital of the empire, it also received a prefect of the city, who, like the prefect in the west, was the direct representative of the emperor, and next to him the first person in the city. The whole administration of the city, all its corporations and institutions were under his superintendence; every month he made a report to the emperor of the transactions of the senate and people (Symmach., *Epist.*, x. 44); in the assemblies of the senate he gave his vote before the consulars (Cassiod., *Variar.*, vi. 4), and was the medium through which the emperors communicated with the city.

PRÆMUNI'RE (used for *præmonere*, 'to forewarn,' Co. Lit., 129 b) is the first word of an antient writ by which a party was summoned before the king to answer a charge of contempt against him. The commencement of the writ was as follows: 'Præmunire facias A. B. quod sit coram nobis,' &c. The contempt consisted in the doing of some act in derogation of the allegiance due to the king. In case of conviction, the judgment was, that the defendant (who had committed the offence of throwing off his allegiance) should be thenceforth out of the king's protection, and his lands and tenements, goods and chattels, forfeited to the king, and his body should remain in prison at the king's pleasure. The word præmunire, as now used, has two meanings; one the writ itself, the other the offence to which the writ is applicable.

In late times it seems to have been considered that the offence was referrible only to attempts to introduce the papal authority into this kingdom; but it would appear that any attempt to introduce foreign jurisdiction or usurp upon the 'kingly lawes of the crown' was equally within the penalties of a præmunire. It is true that most of these attempts did relate to the papal jurisdiction, and the statute 16 Rich. II., c. 5, called the statute of præmunire, relates only to such attempts. But the statute 27 Edw. III., c. 1, referred to by 16 Rich. II., c. 5, visits an analogous offence with the same penalty where one 'shall draw any out of the realm in plea whereof the cognizance pertaineth to the king's courts, or whereof judgment is given in the king's courts, or which do sue in any other court to defeat or impeach the judgment given in the king's court, &c.;' and this applied even where the other court was within the realm, as by suing in chancery to defeat a judgment at common law, or suing before other courts, such as the ecclesiastical, admiralty, &c., in matters whereof the king's court had jurisdiction. These were offences also punishable at common law. (See also 35 Edw. I., 2, 3.)

Numerous statutes have defined what shall be such a contempt as amounts to a præmunire. Most of the earlier are directed against *provisors*, as they were called, or persons who purchased from the court of Rome provisions for holding abbeys or priories, &c., before those benefices were vacant (25 Edw. III., stat. 5, c. 22, stat. 6), or for exemption from obedience to their proper ordinary (2 Henry IV., c. 3), or bulls for exemption from tithes (2 Henry IV., c. 4), or those who held benefices in favour of aliens, &c. (3 Rich. II., c. 3; 7 Rich. II., c. 12; 12 Rich. II., c. 15; 13 Rich. II., stat. 2, c. 2), or those who purchased (procured) bulls, sentences of excommunication, &c. against the king (16 Rich. II., c. 5). This statute recites that 'so the crown of England, which hath been so free at all times that it hath been in no earthly subjection, but immediately subject to God in all things touching the regalty of the same crown, and to none other, should be submitted to the pope, and the laws and statutes of the realm by him defeated and avoided at his will, in perpetual destruction of the sovereignty of the king our lord, his crown, his regalty, and of all his realm, which God defend.' During the time of Henry VIII., several statutes applied the penalties of a præmunire to those who sued for or attempted to enforce any bull, &c. from Rome, or appealed there (23, c. 2; 24, c. 12; 25, c. 19, 21; 28, c. 16), or refused to elect a bishop named by the king (25, c. 20). By 5 Eliz., c. 1; 13, c. 2; 27, c. 2, it was applied to those who refused to take the oath of supremacy, or defended the pope's jurisdiction, abetted publishers of bulls, &c., or sent relief to Jesuits beyond seas.

About this time the penalties of a præmunire ceased to be confined to the class of offences already enumerated. The following enactments however related solely to such offences: 13 Ch. II., s. 1, c. 1, whereby persons who advisedly assert that both or either house of parliament have a legislative authority without the king: 4 Jac. I., c. 4; 1 W. & M., s. 1, c. 8, those who refuse to take the oath of allegiance are declared guilty of a præmunire. By 7 & 8 Will. III., c. 4, serjeants, barristers, attorneys, &c. are subjected to the same penalties if they practise without taking the oath. By the 6 Anne, c. 7, a malicious or advised assertion that the then pretended prince of Wales or any person other than according to the acts of settlement and union, has any right to the throne of these kingdoms, or that the king and parliament cannot make laws to limit the descent of the crown, amounts to the same offence. And 12 Geo. III., c. 11, attaches the same penalties to all such as wilingly solemnize or assist, &c. at any forbidden marriage of the descendants of George II. who by that act are prohibited to contract marriage without consent of the crown. But during the same period the penalties of a præmunire were attached to persons guilty of various offences of very different characters: to those who molest the possessors of abbey lands granted by parliament to Henry VIII. and Edward VI.; to brokers or agents in any usurious contract where above 10 per cent. interest is taken, by 13 Eliz., c. 8; to those who obtain any stay of proceedings other than by arrest of judgment or writ of error in any suit for a monopoly, by 21 Jac. I., c. 3, s. 4; who obtain an exclusive patent for the sole making or importation of gunpowder or arms, or hinder others from importing them, by 16 Ch. I., c. 21. By 12 Ch. II., c. 24, the king's prerogative of purveyance, by which goods were formerly taken at a certain price for the king's use without the consent of the owners [Purveyance] was abolished; an action was given to parties against whom it was attempted to be enforced, and those who should attempt to delay execution in such action, save by intervention of the court in which it was pending, were subjected to the penalties of a præmunire. By the Habeas Corpus Act, 31 Ch. II., c. 2, the same punishment, besides others, is incurred by those who deprive or assist in depriving any subject of this realm of his liberty contrary to that act. By 6 Anne, c. 23, if the peers of Scotland convened to elect their representatives in the British parliament, treat of any other matter than the election, they are guilty of a præmunire. After the breaking of the South Sea bubble, those who thereafter engaged in such undertakings were, by 6 Geo. I., c. 18 (now repealed), made liable to the penalties of a præmunire.

The punishment of a præmunire has already been stated. After judgment, the defendant might formerly have been killed by any man. 'But Queene Elizabeth and her parliament, liking not the extreme and inhumane rigor of the law in that point,' made it unlawful to slay him (5 Eliz., c. 1). Still, being out of the protection of the law, he cannot sue in any action (Co. Lit., 129 b), and he forfeits all his goods and chattels, his lands and tenements in fee, and his life interest in lands in tail. (3 *Inst.*, 119, 'Of Præmunire.') Prosecutions for this offence are now almost obsolete.

PRÆNESTE. [Palestrina.]

PRÆPEDI'TUS, a name assigned by MM. Duméril and Bibron to a genus of reptiles belonging to the Saurophthalmic group of their *Lizards Scincoidiens ou Sauriens Lepidosaures*; and placed by those distinguished erpetologists next to *Scelotes*, Fitz. (*Bipes* and *Pygodactylus*, Merrem; *Bipes*, Cuv. and Gray; *Zygnis*, Wagl.). [Bipes.]

Præpeditus is the *Soridia* of Gray, whose name has the priority.

The nostrils open in the middle of a plate or scale. There are no auricular apertures, and no anterior limbs. The two posterior feet are simple stylets; the body is anguiform, and the scales are smooth.

Example, *Soridia lineata*, Gray; *Præpeditus lineatus*, Dum. and Bibr.

MM. Duméril and Bibron state that the following should be added to Mr. Gray's characters: teeth conical, simple; palate smooth; tongue arrow-headed, scaly, notched at its point—if, as they suppose, Mr. Gray's species is not different from a Cape Scincoidian which they saw in Dr. Smith's collection at Chatham; and they think that the locality (New Holland) assigned by Mr. Gray to his species is erroneous.

PRAETOR, a word which apparently contains the same elements as the verb *præire*. The consuls were originally called praetors, but the name praetor was specially appropriated to a magistrate called the praetor urbanus, who was first appointed B.C. 365. He was called a colleague of the consuls, and was created with the same auspices. (Liv., vii. 1.) The praetor was at first only chosen from the patricians, as a kind of compensation to them for admitting the plebeians to fill one of the consulships. (Liv., vi. 42.) In the year B.C. 336 the first plebeian praetor was created.

The praetor, in his origin, seems to have been a kind of third consul. While the consuls were at the head of the armies in the field, the praetor exercised the consular power within the city, in the senate, and in the comitia. He also administered justice ('jus in urbe dicebat,' Liv., vi. 42). On some occasions the praetor led the armies of the state. (Liv., vii. 23, &c.) Yet the imperium of the praetor was less than that of the consuls, to whom he owed obedience. There was also a distinction in his insignia of office, for the praetor had only six lictors, from which circumstance he is called by Polybius 'the general with six lictors' (ἡγεμὼν or στρατηγὸς ἑξαπέλεκυς, and sometimes simply ἑξαπέλεκυς, &c.). It appears from Livy that the praetorship was originally given to a consul of the preceding year; and after the plebeians obtained admission to this magistracy, it was given alternately, at least for a time, to the patrician and plebeian consul of the preceding year. As the praetor was a kind of substitute for the consuls, there was nothing in the nature of the office which limited the number: and accordingly in B.C. 247, another praetor, called Praetor Peregrinus, was created, who administered justice in matters between citizens and foreigners, and in matters between foreigners only. It is conjectured that one praetor was a patrician and the other a plebeian, but this does not appear certain. If one of the praetors left the city to command the army, the other had the authority of both within the city; and when the military service required it, the imperium of a praetor was prolonged for another year by the senate or the comitia. When conquests were made beyond the limits of Italy, and foreign countries were reduced to the form of provinces, praetors were sent to govern them. Thus two new praetors were appointed for Sicily and Sardinia (B.C. 227), and subsequently two more when the two provinces of Spain were formed. The provinces of the praetors were determined annually by the senate, and distributed among them by lot. As the judicial labours of the praetors increased, they generally spent their year of office at Rome, and then took the charge of a province with the title of propraetor. Sylla increased the number of praetors to eight. The praetor urbanus had the highest rank, and was specially called praetor: the duties of his office required his constant attendance at Rome, and he could not leave the city for more than ten days at a time. He had the troublesome and expensive duty of superintending the Ludi Apollinares and giving gladiatorial shows to the people. Julius Cæsar increased the number of praetors to ten, then to twelve, fourteen, and sixteen; Augustus reduced the number to ten, then again raised it to sixteen, and finally fixed it at twelve. Under Tiberius there were sixteen. A permanent praetor for fidei commissa was subsequently appointed (*Dig.* i., tit. 2, s. 3), and another for matters between the Fiscus and private individuals; and a praetor was appointed by the emperor M. Antoninus (Capitol. *M. Anton.*, c. 10) solely for matters relating to guardianship (tutela).

An office like the praetorship in some respects may be traced further back than the first election of a praetor; and the vicarious duties of the office appear clearly in the functions of the antient prafectus urbi [PRÆFECTUS URBI], whose office became of less importance on the appointment of the praetor urbanus. As late as the time of Cicero (*Ep. Fam.*, x. 12, xii. 28), we find the praetor performing the duties of the consuls in their absence.

The praetor urbanus became the chief magistrate for the administration of justice, and in this respect his office was the most important in the state. He was one of the magistrates who had the Jus Edicendi (Gaius, i. 2), or of publishing edicta, which were the foundation of a body of law known under the names of Jus Honorarium or Praetorium. The praetor peregrinus had also the Jus Edicendi: and the edicta of these two praetors formed the largest body of this edictal law. The edicta of the praetor urbanus were published generally on entering on his office, and occasionally during its continuance. It is difficult to describe the edicta in exact terms, but they had reference only to civil actions, and their object was generally to provide for cases unprovided for by the existing laws, and mainly by introducing new kinds of actions (actiones utiles) when the actions of the old law (actiones directae) did not apply, and fixing the mode of procedure. They often adapted a new form to an existing right, and they contrived by various legal fictions to accommodate the limited provisions of the old laws to the existing wants of society; but in all these proceedings we clearly discern a rectitude of intention and singleness of purpose as the characteristic of the edict. The praetor also interfered in a summary way by his Interdict, particularly in matters of possession [POSSESSION], in the case of a man who was of unsound mind and incompetent to manage his property, or a prodigal who was wasting his substance; in which cases the praetor appointed a curator, when the laws of the Twelve Tables had not provided for one. He also gave relief in cases of fraud whenever the law had made no provision (*Dig.* 4, tit. 3), and generally by the doli exceptio and the in integrum restitutio, in the case of minors, he set aside fraudulent transactions. (Savigny, *Von dem Schutz der Minderjährigen*, *Zeitschrift* x. 261.) It is stated that the praetors would sometimes vary their edicta in the course of the year, till this was forbidden by a decree of the senate, and finally by a lex Cornelia (B.C. 67). This gave to the edict a character of greater stability. It seems that the edicta of his predecessors, though not absolutely binding on an actual praetor, were frequently adopted by him. Indeed we cannot conceive that the prætorium jus could have acquired that stability and consistency which it undoubtedly had acquired, even in the time of Cicero (*Leg.*, i. 5), if the chief rules that were established by the praetors were not observed by their successors: The Roman jurists found ample matter for comment in the praetors' edicta, and a large part of their writings had for their object the exposition of the legal principles contained in them. Under the emperor Hadrian the edicta of the praetors were collected and arranged by Salvius Julianus, a distinguished jurist, under the name of Edictum Perpetuum, and from this time the progressive development of the Roman law by the praetors' edict ceased. The constitutions and rescripts of the emperors supplied the place of the edict.

In civil matters, except in the cases of interdicts, the praetor did not give final judgment. (Gaius, iv. 139) [INTERDICT.] A person who had a claim against another, which was disputed, applied to the praetor for the purpose of obtaining a reference of the matter in dispute to a judex or judices, with the proper instructions, which were contained in the formula. [JUDEX.] The proceedings before the praetor were *in jure*, and had reference to the pleadings and various proceedings by which the matters in dispute between the two parties were to be brought to issue.

The praetors also presided in quaestiones, or judicial inquiries into crimes, or that class of offences which were the subject of judicia publica. Sometimes persons (quaesitores or quaestores) were appointed on special occasions to preside at such trials. After the number of praetors had been increased to six, the praetor urbanus and peregrinus exercised their usual jurisdiction, and the other four presided in quæstiones as to repetundæ, peculatus, majestas, and ambitus. These quæstiones were called perpetuæ (Cic., *Brut.*, 102), apparently because the praetors exercised the functions of quaestores during the whole year of office, and not, as was the old practice, on the particular occasion only of their appointment as quaestores. Still extraordinary quaestores might be appointed. Sulla, by various leges, added to the number of quaestiones perpetuæ, and at the same time made two additional praetors.

The importance of the praetor urbanus and peregrinus must have declined after the time when their edictal power ceased to be exercised, which, as already observed, was in the time of Hadrian. (Savigny, *Von dem Schutz*, &c.) It is true that Gaius, who wrote after the time of Hadrian, seems to speak of the praetorian jus edicendi as existing in his time; and so it might in theory, though not in fact. Further, he is speaking of praetorian edicta as one of the sources of Roman law, and it was not necessary for him to define accurately the time when they had ceased to have any force, or had almost fallen into disease.

The praetors existed till a late time under the empire, and still had some jurisdiction. [Praefectus Urbi.]

PRÆTORIANS was, in the time of the Roman republic, the name of a select cohort which attended the person of the prætor or commander of a Roman army. Sallust (*Catilina*, 60) says that Petreius, finding that Catilina and his followers defended themselves more stoutly than he expected, ordered, as a last expedient, the prætorian cohort to charge the insurgents, and this decided the fate of the battle. In the time of the triumvirate, Octavian and Antony greatly increased the number of the prætorians. Appianus (*Bell. Civ.*) says that after the battle of Philippi they dismissed all those soldiers who had served their time, except 8000 men who requested to remain in the service, who were distributed in prætorian cohorts attached to the persons of the triumvirs. After the final overthrow of the republican party, Augustus formed the prætorians into nine cohorts, and fixed their station in the capital as guards to his person, (Suetonius, *August.*, 49.) They became in fact, under the emperors, what the regiments of guards or household troops are in the actual monarchies of Europe, a select and privileged body in the army. But besides their ordinary military duties, they had also the charge of state prisoners, and often acted as executioners. The prefect of the prætorium was the commander of the whole body of prætorians. They were all picked men, chosen from Old Latium, Umbria, Etruria, and the older Roman colonies, and they were proud of their origin. (Tacitus, *Annal.*, iv. 5.) Under Vitellius the prætorian cohorts were increased to sixteen. (Tacitus, *Hist.*, ii. 93.) In the frequent revolutions of the empire the prætorians acted a conspicuous part, and often determined the fate of an emperor, and the choice of another; as in later times the janissaries did with regard to the Turkish sultans. Diocletian reduced the number of the prætorians, and Constantine entirely disbanded them.

PRAGMATIC SANCTION is a term that has been used to signify a solemn ordinance or decree of the head or legislature of a state upon weighty matters. The use of it appears to have originated with the Byzantine empire. It was used in France at an early period of the monarchy. In 1268 Louis IX. issued a pragmatic sanction concerning the discipline and temporalities of the Gallican church. (Bochellus, *Decreta Ecclesiæ Gallicanæ*.) But the most celebrated pragmatic sanction is that issued by Charles VII. of France, in 1438, in consequence of the schism in the church between the council of Basle and Pope Eugenius IV. [Eugenius IV.] In this dilemma, Charles, doubting which of the two contending parties was in the right, assembled a national synod at Bourges, in which legates attended both from the pope and from the council of Basle. In this synod it was decided that the earlier decisions of the council of Basle issued previous to the schism, and which had been ratified by Eugenius himself, were binding upon the church. One of the most important of these decisions was that which asserted the supremacy of the general council over the pope. Twenty-three articles were consequently signed by the king, with the concurrence of both his spiritual and lay advisers, for the regulation of the discipline of the Gallican church, framed upon the decrees of the council of Basle, and these constitute the pragmatic sanction of Charles VII. The most important of these articles were: 1. The election of bishops was declared to belong to the respective chapters, subject to the royal sanction. 2. The court of Rome was no longer allowed to interfere with the disposal of the minor benefices. 3. The cases in which appeals to Rome were allowed were strictly limited. 4. The annates, or first-fruits, paid to Rome, were abolished. About twenty years after, Louis XI., wishing to please pope Pius II. in order to obtain the investiture of Naples for the duke of Anjou, gave up the pragmatic sanction, the original of which he sent by the bishop of Arras to Rome, where it was ignominously dragged through the streets. The parliament of Paris remonstrated, and some years after, Louis having quarrelled with the pope, the pragmatic sanction again obtained the force of law. That edict was in fact the foundation of the liberties of the Gallican church. The concordat of Francis I. with Leo X. made considerable improvements in the regulations of the pragmatic sanction, and gave rise to a strong opposition on the part of the parliament of Paris. [Concordat.]

Another pragmatic sanction, which has acquired an historical celebrity, is that issued by the emperor Charles VI., in his capacity of king of Bohemia and sovereign of the other hereditary states of the House of Austria. This pragmatic sanction regulated the succession in his family. [Habsburg, House of; Charles VI. of Germany.]

PRAGUE, the capital of Bohemia, is situated nearly in the centre of the kingdom, in 50° 5′ 19″ N. lat. and 14° 25 E. long. It lies on both banks of the Moldau, in a narrow valley which is shut in by eminences, on the sides of which a great part of the city is built. In size and beauty Prague is the third city in Germany, and produces a very striking effect when viewed at a distance, by its commanding situation, the lofty steeples of its numerous churches, and the fine palaces and public buildings. The city consists of four parts, formerly called towns, but now designated as quarters. There are on the right bank of the river—1st, the old town, which is gloomy and closely built, and which includes the quarter assigned to the Jews, who, as in some other towns in Germany, are not allowed to reside amongst the Christian population. This quarter is a real labyrinth of crooked mean streets, with only 278 houses, in which nearly 7000 Jews are crowded together, so that many an inconsiderable house belongs to ten different owners, and two or even three families live in one room. 2nd, the new town, which is larger than the old town, which it completely surrounds. The new town has finer and broader streets, spacious squares, lower houses, and a healthy site. On the left bank of the Moldau the two eminences called the Laurenzberg and the Schlossberg form a semicircle, enclosing a valley in which the quarter called the Kleinseite (or Little Prague) is built. This quarter is much smaller than the old town, but contains many considerable gardens, fine palaces, and lofty houses. The fourth quarter, called the Hradschin (pronounced Radshin), is built on the Schlossberg (the Palace Hill). This is the smallest but the finest part of the city, in which there is a great number of magnificent palaces. The town of Wissehrad, which joins the new town, and the village of Smichow, on the left bank of the Moldau, are reckoned as part of Prague. Including all these parts, the city is ten miles in circumference, and two miles and a half in diameter. There is likewise a new suburb called the Karotenenthal. The city is surrounded with fortifications, and has eight gates. Though some portions, particularly in the old town, are gloomy and ill built, having many short, crooked, and narrow streets and lanes, it has been much improved of late years. The old town and the Kleinseite are connected by the celebrated bridge over the Moldau, the construction of which was commenced by Charles IV. in 1358, and completed by Vladislaus II. in 1507. It is 1790 Vienna feet long, 35 broad, and has 16 arches: it is adorned with 29 statues and groups of saints, and has an antient tower at each end. There are in the city forty-six Roman Catholic and two Protestant churches, nine synagogues, fifteen monasteries, and sixty-eight palaces. It may be imagined that even a partial description of them would far exceed our limits, and we must confine ourselves to those most worthy of notice. The metropolitan church of St. Veit, in the Hradschin quarter, was commenced in the beginning of the tenth century, but not completed till 1500. The steeple is 314 feet high, and affords a magnificent view of the city. It is a fine specimen of antient German architecture, and the curiosities which it contains would take a volume to describe them. There are the sepulchres of several emperors and kings, of Bohemian princes, and remarkable men. Of the twelve chapels in this cathedral, that of St. Wenzel is richly adorned, and contains paintings of the fourteenth century, a Madonna, said to be by Holbein, and numerous antiquities and relics. The great ornament of the cathedral is considered to be the richly adorned monument of St. Nepomuck (Nepomucenus), the patron of Bohemia. The other old church is the cathedral on the Thein, which was built at the end of the ninth century, but has been disfigured by various additions in the course of so long a time. It contains the tomb of the great astronomer Tycho Brahe, who died in 1603. Many of the more modern churches, which are chiefly in the Italian style, are worthy of attention. Among the palaces, the Imperial palace in the Hradschin is the most remarkable building in the whole city, both for its immense extent and its fine and commanding situation. Of the 440 apartments, the hall of Vladislaus is a noble work of Gothic architecture, second only to that of Westminster. King Charles X. of France and his family resided for some years in this palace after their expulsion from France. Among the other palaces the most magnificent are those of the famous Wallenstein, of Count Czerny, of Count Ledebour, and two of Prince Schwarzenburg. The principal public buildings are—1, in the old town, the Collegium Clementinum, built by the Jesuits, in which Joseph II. placed the archiepiscopal seminary, where from 300 to 400 pupils are educated as secular priests. It contains many lecture-rooms, the academy of painting, a gymnasium, the university library, the observatory, a printing-office, and several scientific collections. The old town contains also the theatre, the mint, and several palaces. 2. In the new town, the senate house, the custom-house, and the military hospital, one of the largest and most regular buildings in the city. Most of the hospitals and charitable institutions are in the new town. 3. In the Kleinseite, the arsenal and the government-house. 4. In the Hradschin, the archbishop's palace.

The university of Prague is the oldest in Germany. It was founded in 1348 by Charles IV., on the model of that of Paris, and had so many privileges and able professors that, up to 1409, it had a large number of students. But after the death of Charles, disputes arose between the foreigners, whom he favoured, and the natives. Wenzel allowed the Poles, Bohemians, and Saxons together only one vote in elections, while the Bohemians had three votes. This caused many thousands of the former to leave the university, and gave occasion for the foundation of the universities of Leipzig, Ingolstadt, Rostock, and Cracow. From that time the university could never recover, till Maria Theresa, Joseph II., and Francis II. became its protectors. It has now 53 professors, 14 assistants, and above 2000 students. The medical faculty in particular is most liberally provided for. Connected with it are a veterinary school, a school for midwifery, five clinical institutions, one of them for surgery, zoological and anatomical collections, a botanic garden, a chemical laboratory, and an observatory, most amply furnished by Joseph II. and Francis II. The annual expense of the university is 261,717 florins. There are three gymnasia to prepare students for the university. The schools for the education of persons not intended for the learned professions and for the inferior classes are very numerous. There are likewise a polytechnic institution, an economical society, an academy of the fine arts, and a musical conservatory, but above all the Academy of Sciences, and the Bohemian National Museum, founded by Count Colowrat, with important collections, and libraries. The university library consists of 130,000 volumes, and 4000 rare MSS. of classical and Slavonian literature, besides which there are eight public and several private libraries open for public use. The Imperial Cabinet of Natural History has been greatly increased of late years. The charitable institutions, for instance the hospitals of the brothers and sisters of Charity, are in the most admirable condition. There is a great number of physicians for the poor, a vaccine institution, twelve hospitals, of which that called the General Hospital receives annually from 1300 to 1600 patients, without regard to the difference of religion, which is not the case in the others; a lunatic asylum, a lying-in hospital, &c. The poor are lodged, maintained, and clothed partly by private societies, partly in poorhouses, and there are also ten public and private institutions for widows and orphans, among which are an asylum for the blind, and another for the deaf and dumb.

Prague has extensive manufactories of various kinds, in all about sixty manufactories of cotton, hosiery, silk, wool, leather, hats, gloves, earthenware, gold and silver, plated goods, mathematical and musical instruments, glass, buttons, snuff and tobacco, paper and paper-hangings; besides which there are breweries, saltpetre-works, and many others. Prague has a very flourishing trade, being the centre of that of Bohemia: the transit trade is considerable, and there are three great annual fairs.

Though Prague has long ceased to be the residence of the sovereign, it is the seat of the government of the kingdom and of the courts of justice, and is the head-quarters of the military governor of the kingdom, with a garrison of 12,350 men. It is also the residence of numerous families of nobility and gentry, whose incomes are such as to exempt them from the necessity of living in retirement, though not to enable them to figure at the court of Vienna. But it must be observed that the higher nobility come little in contact with the other classes, and in general the pursuit of pleasure is more attended to by the great mass of the inhabitants than the more refined enjoyments of science and learning. There is but little, comparatively speaking, of what we should call society. The pleasures of the country, promenades, and gardens, are not much sought after at Prague. There are however some islands in the Moldau laid out in walks and tea-gardens; the palace garden and that of Count Waldstein (Wallenstein), which are open to the public twice a week; the grounds of Prince Kinsky and Baron von Wimmer, and some others. The environs of Prague abound in natural beauties. The great delight however of the citizens are balls, concerts, masquerades, the theatre, and religious festivals, some of which, for instance that of St. Nepomuck on the 16th of May, are celebrated with much pomp.

Prague is an antient city, but the time of its foundation is uncertain. Some say it was built by the Marcomanni, and called in the fifth century Marobodonum; others that it was founded by the Czeches in 611; and others ascribe its origin to Queen Libussa in 723. The city has suffered frequently and severely by the calamities of war, especially in the troubles caused by the persecution of the Hussites in the fifteenth century. In 1620, in the contest between the elector palatine and the emperor for the crown of Bohemia, a battle was fought on the White Mountain, two miles from the city, in which the Imperial troops were victorious, and the elector Frederick V., son-in-law of James I. of England, lost the crown. In 1741 a French corps was blockaded in Prague, and made a vigorous defence, and when reduced to the last extremity by famine, evacuated the city and retreated in good order. In 1744 Frederick II., with 100,000 men, appeared before Prague, of which he got possession, but ten weeks afterwards was obliged to evacuate it. There was some smart fighting in the city itself; the Prussians left 2000 prisoners, 132 cannon, and 12 mortars in the hands of the Austrians. In 1757 Frederick again besieged Prague, and immense damage was done by the bombardment; nearly 900 houses were destroyed, and the churches suffered severely. The victory of the Austrians at Collin obliged Frederick to raise the siege, since which time Prague has not seen an enemy before its walls.

The inhabitants of Prague are chiefly Bohemians (Czeches) and Germans, and most of them speak both languages. With respect to religion, the vast majority are Roman Catholics, as may be judged by the number of their churches. The present population is at least 120,000, including about 7000 Jews and the garrison.

PRAIRIES. [PLAINS.]

PRAKRIT. [SANSKRIT.]

PRAM, CHRISTIAN HENRIKSEN, who has left a name of some eminence in Danish literature and poetry, was born September 4th, 1756, in Guldbrandsdalen. After having been educated by his father, who was a clergyman, and next passing a short time at the school at Fredericksborg, he was sent to the university of Copenhagen, where he applied himself to the study of law and political economy. He did not however adopt the former as a profession, and though he afterwards continued to give his attention to the other, poetry and literature became his chief pursuits. His continuing to apply himself to a study so much at variance with his taste for poetry as that of political economy, is accounted for by his being appointed, in 1781, to a high situation in the Chamber of Commerce. Shortly afterwards he married, and, in order to increase his income, set up the 'Handelstidende,' or 'Commercial Journal,' which he first carried on in conjunction with Cramer and Ehrhart, and afterwards by himself, but gave it up at the end of five years, though the publication itself has since continued.

From that time he devoted himself, as far as his official duties would permit, to literature, and had indeed already signalised himself in it by his 'Stœrkodder,' which appeared in 1785, and the success of which most probably induced him to withdraw from the publication above mentioned, and employ his pen more congenially with his own feelings. This poem was then altogether a novelty in Danish literature, and though it does not answer to the character of an epic, it is something very superior to a Riimkronik, or mere chronicle in verse, as its author modestly styles it, being a romantic narrative founded upon the traditions of northern legend and mythology, and recording the hero Stœrkodder's adventures in search of Skirner's mystic sword and other talismans. Thus considered, this production of Pram's (in fifteen cantos) is a classic one of its kind, and is one that places its author by the side of Ariosto and Wieland.

Shortly afterwards he commenced, with the assistance of Rahbek, the 'Minerva,' one of the best literary periodicals of its time in Denmark, and one which also discussed many important political and statistical questions. Few could have been better qualified than Pram for conducting such a miscellany, he being equally at home in both departments of it; and to the literary part he contributed a number of his minor pieces both in prose and verse. Among his other services to literature may be reckoned that of having, together with Thaarup, Baggesen, and Höst, established the Scandinavian Literary Society in 1796; of which institution he was president from 1811 to 1818. He may also be ranked among the Danish dramatists, having, besides his 'Damon and Pythias,' and 'Fingal and Frode,' produced several comedies and some minor pieces for the stage.

On the Chamber of Commerce being united, in 1816, with the Board of West India Affairs, Pram retired from his situation in the former; but though his various emoluments had been very considerable for a series of years, and though he was allowed a pension of 1800 dollars, he was in such straitened if not embarrassed circumstances, that after the death of his wife, in 1819, he resolved to accept an official appointment in the island of St. Thomas. He accordingly proceeded thither in the following spring, departing without the hope of ever revisiting his native land, being then in his sixty-third year. He died at St. Thomas's, November 25th, 1821.

A collection of his miscellaneous poems and prose works was edited by Rahbek, in 4 vols., 1824-26. Oehlenschläger, who has drawn his character, describes him as a man of powerful mind and excellent disposition, though subject to occasional violence of temper, and of great and varied talents and attainments. Of his 'Stœrkodder,' he says that it possesses many detached parts of very great beauty; but among all Pram's productions he gives the preference to the poem entitled 'Emilias Kilde.'

PRANGOS, a genus of plants of the natural family of Umbelliferæ, tribe Smyrneæ, so named by Dr. Lindley from the name by which the only species is known in its Tartarian habitat, where it was discovered by Mr. Moorcroft, in the neighbourhood of Imbal or Droz, and which he visited for the purpose of examining into the reputed qualities of this plant, of which the accounts seemed to border on exaggeration. Almost all the knowledge which we possess respecting the plant, is derived from the observations of that lamented and enterprising traveller.

The Prangos Hay-plant is herbaceous and perennial, having a large fleshy root-stalk, usually measuring at the top from eighteen to twenty-two inches in circumference, and formed by the aggregation of an infinite number of crowns or winter-buds, clustered together at or above the surface of the ground. These crowns being closely covered by the fibrous remains of the old leaves, are thus protected from the frosts of winter. The crop consists of the leaves, which rise in abundance from each crown, are finely cut, about two feet in length, and have a highly fragrant smell, extremely similar to that of very good new clover hay.

This Mr. Moorcroft considered as a most important and interesting object of rural economy, and says that the properties of prangos as a food appear to be heating, producing fatness in a space of time singularly short; it is also destructive to the fasciola hepatica, or liver-fluke, which in Britain, after a wet autumn, destroys some thousands of sheep by the rot. The last-mentioned property, of itself, if it be retained by the plant in Britain, would render it especially valuable to our country. But this, taken along with its highly nutritious qualities, its vast yield, its easy culture, its great duration, its capability of flourishing on land of the most inferior quality and wholly unadapted to tillage, impart to it a general character of probable utility unrivalled in the history of agricultural productions. When once in possession of the ground, for which the preparation is easy, it requires no subsequent ploughing, weeding, manuring, or other operation, save that of cutting and of converting the foliage into hay. Of its duration he relates that its seeds, having been carried westward along with those of yellow lucerne, above forty years ago, and sown on the eastern frontier of Cashmere, vegetated, and that the plants of the first growth still remain in a flourishing condition. He conceived that by the cultivation of this plant, moors and wastes hitherto uncultivated may be made to produce large quantities of winter fodder, and that the yield of high lands and downs enjoying a considerable depth of soil may be trebled.

Notwithstanding the highly favourable accounts given by Mr. Moorcroft, it is doubtful whether the prangos, though highly deserving of trial, would be so valuable as he anticipates in the situations which he points out. Dr. Falconer, in his visit to Cashmere and Tibet, found it in the latter, as well as on a low trap hill in the former, but not so vigorous in the Cashmerian as in its Tibetan habitat. He states that though abundant in various directions, the Cashmerians do not esteem it of any value. Dr. F. is of opinion therefore that its importance has been much over-estimated, in consequence of its being the only food in many of the bleak and barren tracts of Tibet. In Cashmere, where there is a superabundance instead of a deficiency of pasturage, it is accordingly much less esteemed. But in many barren and bleak situations, with considerable cold in winter, it would no doubt be a valuable acquisition, if the climate of the country be not too moist. Parts of the Cape of Good Hope, New Holland, and Van Diemen's Land seem well suited to it.

Arrian, in describing Alexander's expedition across the mountains which he calls Caucasus and Paropamisus (iii. 28), says, nothing but Silphium and the turpentine-tree grow there, notwithstanding which it is very populous, and multitudes of sheep and neat cattle are seen, for they feed upon Silphium, of which the sheep especially are very fond. This bears so close a resemblance to the prangos, both in locality and properties, that it is as likely to have been the Silphium of the antients as the assafœtida plant, which it is supposed to be by others. [SILPHIUM.]

PRANI'ZA. [ISOPODA, vol. xiii., p. 56.]

PRA'SII. [HINDUSTAN, p. 223.]

PRATI'COLA. [SYLVIADÆ.]

PRATINCOLE (*Glareola*, Briss.), a genus of birds allied to the plovers. [PLOVERS.] Temminck places the form under his order (the 11th) *Alectorides*.

Generic Character.—*Bill* short, hard, convex, curved for upwards of half its length, and compressed towards the point. *Nostrils* at the sides of the base, oblong, and obliquely cleft. *Legs* feathered nearly to the knee; toes, three before and one behind, the outer united to the middle one by a short membrane; claws long, and drawn to a fine point. *Wings* very large, the first quill-feather the longest. *Tail* more or less forked. (Gould.)

Example, *Glareola torquata*, *Hirundo Pratincola*, Linn.

Description.—*Old Male and Female.*—Summit of the head, nape, back, scapulars, and coverts of the wings grey-brown; throat and front of the neck white slightly tinged with reddish, which colour is encircled or framed, as it were, by a very narrow black band, which ascends towards the corners of the bill; space between the eye and the bill black; breast whitish brown; under coverts of the wings chestnut red; lower parts white, clouded with reddish; coverts of the tail and origin of the caudal feathers pure white, the rest blackish towards their end; bill black, red at its base, iris reddish brown; naked circle round the eyes bright red; feet reddish ash; tail very much forked. Length rather more than nine inches. (Temm.)

In this state it is the *Perdrix de Mer* of Brisson, &c.; the *Perdrix de Mer ordinaire et à Collier* of Gerard; *Austrian Pratincole* of Latham; *Das Rothfüssige Sandhuhn* of Bechstein; *Das Oestrichische Halsband* and *Südliche Sandhuhn* of Brehm; and *Pernice di Mare* of Savi.

Varieties.—The grey brown brighter or deeper; the white of the throat more or less clouded with reddish or bright russet; the gular black band more or less intense in colour, and often accompanied by a very small white line. The band too is often only indicated by small black spots. (Temm.)

Young.—Upper parts brown ash clouded with deeper undulations and whitish borders; throat tarnished white surrounded with brown spots, disposed so as to replace the band which surrounds this part in the old birds; breast and belly deep grey with brown spots, but sometimes without spots; the tail less forked, and the lateral feather much shorter than in the old.

In this state it appears to be *La Perdrix de Mer à Collier, la grise, la brune, et la Giarole* of Sonnini (Buff.); *La Perdrix de Mer des Maldives, de Coromandel, et de Madras*, of Sonnerat; *Das braunringige Sandhuhn und Gefleckte Sandhuhn* of Bechstein; and *collared* and further varieties of *Pratincole* of Latham.

Food, Habits, Geographical Distribution, &c.—'The genus *Glareola*,' says Mr. Gould, in his great work on the *Birds of Europe*, 'appears to be strictly confined to the old world, no Transatlantic example having ever been discovered, nor indeed are we aware of any form in the ornithology of America which at all approaches the present. Three species are all that are as yet discovered. Of these, two (the *G. grallaria* and the *G. lactea*) are peculiar to the eastern provinces of Asia and Africa; the other, the bird now before us (*G. torquata*), is spread throughout the warm and temperate regions not only of these continents, but Europe also: hence it would seem as if nature endeavoured to make up by extent of habitat for the limitation of species. Still however, although thus diffused, the Pratincole may be said to be truly a native of the eastern provinces of Europe on the Asiatic borders, and especially Hungary, where wide tracts of morass and flat lands, abounding in lakes both fresh and saline, and traversed by mighty rivers, afford it food and security. "In Hungary," says M. Temminck, "among the immense morasses of the lakes Neusidel and Balaton, I have been in the midst of many hundreds of these birds;" and we might add that it is no less abundant in Western Tartary. In England it is only an occasional visitor; but in Germany, France, and Italy, it is a bird of periodical occurrence.'

M. Temminck, in the last part of his *Manuel*, states that it breeds in Sardinia, and that it is very abundant in Dalmatia, on the borders of the lake Boccagnaro, on its spring passage. The eggs he describes as being yellowish white. 'With the long wings and forked tail of the swallow,' we again quote Mr. Gould, 'the Pratincole possesses that rapidity and power of flight for which the bird is so remarkable. It takes its food, which consists of insects, and especially such as frequent marshes and the borders of rivers, while on the wing, darting along in the chase with the rapidity of an arrow; nor is it less distinguishable for celerity on the ground, and often catches its prey as it nimbly runs along. This elegant and graceful bird incubates in the concealment afforded by reeds, osiers, and tall herbage, laying three or four white eggs.'

Glareola torquata.

PRATT, C. [CAMDEN, LORD.]

PRAWN. [SHRIMPS.]

PRAXA'GORAS (Πραξαγόρας), a celebrated physician of Cos, belonging to the family of the Asclepiadæ. (Galen, *De Dissect. Vulvæ*, cap. ult.) His father's name was Nearchus, and he was one of the last of his family who acquired any reputation as a physician. His most celebrated pupil was Herophilus (Galen, *De Different. Puls.*, lib. iv., cap. 3), and he himself was particularly famous for his skill in anatomy and physiology. The titles of several of his works are preserved, but only a few fragments of them remain, together with some of his opinions on medical subjects recorded by Galen and others. He was the first person who pointed out the distinction between the veins and arteries, and affirmed that it is only in the latter that any pulsation is felt, although he believed them to be filled with air (Galen, *De Dignosc. Puls.*, lib. iv., cap. 2), and he accounted for the hemorrhage that occurs when they are wounded by attributing it to an unnatural state, in which the wounded arteries attract to themselves the blood from all the neighbouring parts. He supposed that the heart gave birth to all the ligaments, and that the arteries are ultimately converted into nerves (or ligaments) as they contract in diameter. (Galen, *De Hippocr. et Plat., Decret.*, lib. i., cap. 6.) The brain he supposed to be of no particular use, but merely an expansion of the spinal marrow. His anatomical skill and observations made him introduce several improvements into the theory and practice of medicine; for example, he declared that the pulse indicates the variations of the strength of the disease, a discovery which threw great light on the knowledge of diseases. He imagined the humours of the body to be the cause of all sorts of diseases, and that the vena cava is the seat of an intermittent fever. (Ruf. Ephes.) The greater part of the remedies that he employed were taken from the vegetable kingdom, and we are told by Cælius Aurelianus that he was very fond of emetics (*De Morb. Acut.*, lib. iii., cap. 17). In cases of iliac passion he recommended emetics, as several modern practitioners have also done; and when attended with intro-susception, he ventured to open the abdomen, in order to replace the intestine (Cæl. Aurel., *loco cit.*), an operation that has been proposed and executed in modern times. Notwithstanding the extravagance of some of his opinions, he must have been a very remarkable man, and we may well regret that we know so little of his practice. He lived about B.C. 300 (Ol. 120).

PRAXI'TELES, a sculptor of Greece. Neither the exact time nor the place of his birth is known. It is also remarkable that there is no mention of the master under whom he acquired the rudiments of the art, in which he made such important changes with regard to style, that he is justly considered the founder of a school. The period at which he flourished is however pretty clearly established on the authority of antient writers, as well as by the testimony of some of his works and by the received dates of artists who are classed as his contemporaries. Pliny (*Hist. Nat.*, xxxiv. 8) says Praxiteles flourished in the hundred and fourth Olympiad, at the same time with Euphranor, who was a celebrated statuary and painter. Pausanias (viii. 9) says Praxiteles lived three generations after Alcamenes. He must therefore, according to these statements, be placed at about 360 B.C.; or if, as some antiquaries have contended, he executed a work so late as the hundred and twenty-third Olympiad, or 284 B.C., he may have begun his career as an artist rather later than the time mentioned. It is however quite possible, supposing he lived to an extreme old age, that Praxiteles was practising as a sculptor at the periods recorded, although they include a range of seventy-six years.

Praxiteles was eminent for his works both in bronze and marble, but he seems to have had the highest reputation for his skill in the latter. 'Praxiteles marmore felicior et clarior fuit;' and again, 'Praxitelis ætatem inter statuarios diximus qui marmoris gloria superavit etiam semet.' (Plin., *Hist. Nat.*, xxxiv. 3, and xxxvi. 5.) Pliny and Pausanias enumerate a long list of the productions of Praxiteles. Amongst those in bronze, which appear by the concurrent testimony of antient writers to have been held in the highest estimation, were a statue of Bacchus and another of a satyr, so excellent that it was called by way of distinction Periboetos (the celebrated). He also made a statue of Venus, which was afterwards destroyed by fire; likewise a statue of a youthful Apollo, called Sauroctonos, or the lizard-killer, as he is represented in the act of killing a lizard. Two statues of women are also recorded by Pliny; one of them represented a matron weeping, the other a courtesan laughing. The latter was much admired for its expression. it was believed to be a portrait of the celebrated Thespian courtesan Phryne. Of these works and several others in the same material, the only record that remains is an undoubtedly antient copy, in marble, of the Apollo Sauroctonos. It is too well known to require a particular description in this place. Though defective in some trifling respects of detail, it is not difficult to judge from it of the purity of style, and grace and beauty of form, which must have characterised the original. It is justly considered one of the greatest treasures of the Vatican. Among the works in marble by Praxiteles, the famous Venus of Cnidus must undoubtedly be placed in the first rank. We are told that two statues of the goddess were made; one draped, the other entirely naked. The people of Cos preferred the first; the Cnidians immediately purchased the latter. The fame of this statue was so great that travellers visited Cnidus solely for the purpose of seeing it; and Nicomedes, the king of Bithynia, was so desirous to possess it, that he offered to pay off a heavy debt for them if the Cnidians would consent to give up this celebrated work. The tempting offer was, to the honour of the people of Cnidus, declined. Praxiteles, observes Pliny, 'illo enim signo nobilitavit Cnidum.' There were doubtless many copies of so celebrated a work, and the representation of a figure of Venus on the coins of Cnidus affords unquestionable authority at least for the action and general composition of the far-famed statue. The Venus of Cnidus is mentioned by Lucian as the finest of the works of Praxiteles (Εἰκόνες, c. 4), and from the description in another passage (Ἔρωτες, c. 13, &c.) we may form some notion of the style of this celebrated work. It is also the subject of numerous epigrams in the Greek Anthology. The original work fell a prey to the flames, at Constantinople, in the fifth century, in the dreadful fire which destroyed so many other fine monuments of art collected in that city. The loss of the Venus of Cnidus may justly be considered among the greatest which art has sustained; for no production in antient sculpture, with the single exception of the Olympian Jupiter of Phidias, has received such universal and such unqualified admiration. Two statues of Cupids are also mentioned among the most esteemed works of this master. One of these was so beautiful that it is placed by Pliny quite on an equality with the famous Venus of Cnidus. It was made of marble of Paros. It is thought that a copy of it exists in the collection of sculpture in the Vatican. An anecdote connected with this statue will not be misplaced here. It is recorded, with some slight variation, by more than one antient writer, and it is interesting as, if founded on fact, it tends to confirm, by the artist's own judgment, the high opinions which have been given of two of the most remarkable of his productions; and if it is not authentic as regards the principal actors, it at least shows the feeling that existed antiently respecting the works alluded to. 'Phryne, whose influence over the sculptor seems to have been considerable, anxious to possess a work of Praxiteles, and not knowing, when she was desired to choose for herself, which of his exquisite statues to select, devised the following expedient. She commanded a servant to hasten to him and tell him that his workshop was in flames, and that with few exceptions his works had already perished. Praxiteles, not doubting the truth of the announcement, rushed out in the greatest alarm and anxiety, exclaiming "all was lost if his Satyr and Cupid were not saved." The object of Phryne was answered; she confessed her stratagem, and immediately chose the Cupid.' (Pausanias, i., 20.) Among other works that have been thought worthy to be recorded were two statues of Phryne: one was of marble, and was placed in the temple of Venus at Thespiæ, the native place of the courtesan; the other was of bronze gilt, and was dedicated by her at Delphi, where it had the honour of a distinguished place. Praxiteles appears also to have executed works of a more extensive character and composition. The chief of these were some sculptures that decorated the pediments of the temple of Hercules at Thebes. (Paus., ix. 11.) They represented part of the labours of Hercules.

The style of the school of which Praxiteles may be considered the founder was softness, delicacy, and high finish. We read of few of his productions of a sublime or severe character, such as distinguished the art which immediately preceded his æra under Myron, Phidias, and Polycletus; whose genius led them to represent the more exalted and majestic personages of the antient mythology, as Jupiter, Juno, and Minerva, or the classic forms of heroes, warriors, and athletes. Praxiteles, on the other hand, seems to have been attracted by, and to have devoted himself to, the lovely, the tender, and the expressive. Beyond this he appears to have acquired great skill in execution, and to have had some peculiarities in the mode of finishing his marble. He is said to have declared that he considered those to be his best works which had undergone the process of '*circumlitio*' by Nicias. From the circumstance of Nicias being a painter, it seems reasonable to conclude that this cannot simply mean polishing and rubbing, but that some varnish or encaustic was laid over the surface of the marble after it had left the sculptor's hands, in order to give it a rich softness, similar to what the Italians, in speaking of the flesh surface of marble, call the '*morbidezza di carne*.' Modern ingenuity has vainly endeavoured to discover the process alluded to. It was in all probability a wash of some sort; but whether a simple application of water-colour, or of varnish (if the latter, either the preparation or the statue being warmed to a certain temperature), there are now no certain means of judging. From some experiments that have been made, and the close resemblance produced to some portions of the surface of antient marble, it seems probable that the latter mode of operation approximates in some degree to the antient process.

Praxiteles had two sons, Timarchus and Cephisodotus, or Cephisodorus, both of whom were artists. Pliny says of the latter, 'Praxitelis filius Cephisodotus rei et artis heres fuit.'

There was another artist called Praxiteles living at a later period. He was a modeller and chaser. There was also a painter of the same name, mentioned by Pliny (*Hist. Nat.*, xxxv. 11).

PRAYA. [AZORES.]

PRAYER, a term in theology, used to designate the intercourse passing between human minds and the divine. Language appears not to be necessary to complete the idea which the word represents, since we speak of mental prayer, which is thought directed heaven-wise in adoration or in entreaty without the sentiment of the mind being embodied in words or finding expression by the lips. But its far more common use is to express this kind of intercourse when the sentiment of the mind is embodied in language.

It is a derivative of the verb to *pray*, which signifies to ask for something, and the intercourse of which we have spoken is described by a word which etymologically describes only one part or section of the whole idea, inasmuch as in such intercourse the principal object will always be the supplication of those rich communications of good which God can bestow and man receive.

Prayer springs immediately out of the persuasion that man is not placed on this globe without a protecting and governing power over him, which power is conceived to belong to the One Great, Good, and Wise Being, who was the Creator at first of man himself, and of all the things by which he is surrounded, or which touch in any way his condition. Wherever this idea is fully formed, it seems that the mind must, occasionally at least, fall into the disposition to entreat that the Power, which can do so much for it, would be pleased to exert itself. Whether this government and this ability be vested in some one being, or be supposed to be distributed among many, either equal in power, or supreme and subordinate, the case is the same. Circumstances arise in which it seems that it would be impossible to withhold the mind from assuming the *form* of supplication and the lips from expressing the desires which have sprung in the mind. We accordingly find that prayer has existed from the earliest times when we find men raised into the rank of religious beings, and in any state of religious knowledge, however rude and mistaken the ideas may have been; in times of danger and calamity at least, men have thrown themselves prostrate before a superior power, and entreated its interposition.

Sometimes the prayer may be no more than a brief ejaculation; but if arising in the sincerity of the heart, it is not the less prayer, nor the less regarded by Him who is described in the Holy Scriptures as the God that heareth prayer.

But even in some of the earliest monuments of human thought and feeling we have prayer that has not been mere ejaculation, or even the mere expression of feeling excited by temporary emergencies: and there are come down to us various prayers used by good men in antient times expressive of their desires, and at the same time showing how other topics may properly be introduced and mingled with supplication. There are prayers of men who had not the light of either of the divine dispensations, and there are wise directions concerning prayer in the writings of such men: but the Scriptures, both of the Old Testament and the New, contain many prayers, and many hints and observations respecting prayer, all of which are very instructive, and held in devout reverence by those who receive the persons whose words are there recorded as examples and authorities.

From these examples, and from the instructions incidentally given, Christian divines have deduced certain principles respecting prayer. They have in fact raised a kind of system of prayer: dividing and subdividing the several branches of it. Of these it will be sufficient to say that a prayer, or a body of words expressive of the intercourse, should contain (1) expressions of adoration and admiration of the Mighty Being who is the object of address, by which the mind is brought into a state of confidence that he can grant that which we entreat of him: (2) expressions of our own unworthiness to receive more blessings than he has already seen proper to bestow upon us; either on account of a general persuasion of demerit, or of some particular sin of which we have been guilty. This is thought to be in accordance with the actual state of every one who thus puts himself as it were more immediately in the awful presence of his governor and judge, and to be also salutary to the suppliant as keeping up a sense of proper humility, and a disposition to acquiesce in whatever may be the divine will. (3) Then comes the supplicatory part, in which general or particular blessings are besought, suitable either to the general condition of the person praying, or to the particular circumstances of the moment. (4) Intercession for others, the entreaty of the divine favour for the whole human race, and such blessings as particular classes of persons peculiarly need. This is thought necessary as cherishing the kind and charitable feelings, and leading each individual man to feel himself but as one of a great family of whom God is the common head and the common protector, and whose interests are not to be disregarded in attention to the wants and wishes of an individual member of it. (5) Lastly comes thanksgiving, a devout acknowledgement of past and present mercies, the good which God has given in his natural providence in general, or any special good which he may have granted. Such, according to Christian divines, ought to be the form into which men's thoughts cast themselves when they enter into communion with God: and the various prayers which are delivered in public by the ministers of religion in behalf of multitudes praying together, are for the most part constructed in this form, the differences arising (1) from the selection of different subsidiary topics under each, and (2) from the greater length in which each of these subjects is entered into, according to the feeling or the notions concerning prayer of the individual minister; and such also are the prayers for the most part in those collections of prayers many of which are printed for the use of persons, either in their private or family devotions, who find a difficulty in embodying in words the sentiment of the heart.

Liturgies are of the nature of printed collections of prayers. They are guides to the mode in which the prayers of many assembled in Christian congregations shall be offered. The Book of Common Prayer contains the Liturgy of the English Church as appointed by authority. The effect of liturgies in public worship is to restrain the manifestation of peculiarities in the notions of particular ministers respecting the nature and subjects of prayer: to keep out of the public assemblies of Christians extravagancy and enthusiasm: to bring the will of the community at large to bear on the wills of single ministers in respect of the devotional part of public worship; and to make known beforehand to the people what sentiments will be expressed, and in what form of words, in the service in which they are about to engage.

PREACHING. [Oratory.]

PREBEND (*prebenda*, from *præbeo*, a Low Latin word signifying provision or provender), the portion which the member of a cathedral or collegiate church, called a prebendary [Prebendary], received in right of his place for his maintenance. It was named from the place whence the profit proceeded, which was either from some temporal lands or church preferment attached to that church, or some other church whose revenues were appropriated towards the maintenance of the member of the cathedral or collegiate church. Prebends were of two kinds, simple and dignitary.

A simple prebend was one which had only its revenue for its support; a prebend with dignity, one to which a jurisdiction was annexed; a prebendary holding the latter was styled a dignitary. Some prebends were donative, others in the gift of laymen, who, in case of vacancy, must have presented the future prebendary to the bishop; on this the bishop instituted him, and the dean and chapter then inducted and placed him in a stall in the church. If a bishop were the patron, he collated. At Westminster the king collated by patent, by virtue of which the prebendary took possession without institution or induction. A mandamus lies to compel an election to fill a vacancy. During a vacancy the profits belonging to a prebendary as sole corporator went to his successor; those which he held as member of the corporation aggregate were divided among the dean and chapter. A prebend, being a benefice without cure of souls, was not formerly incompatible to be held with a parochial benefice, but one prebendary could not possess two prebends in the same church, though he might in any other. But now, by 1 & 2 Vic., c. 106, no spiritual person holding more benefices with cure of souls than one shall hold any cathedral preferment; or, holding any cathedral preferment and also any benefice with cure of souls, shall hold any other cathedral preferment; or, holding any preferment in any cathedral or collegiate church, shall hold any preferment in any other. (Comyns's *Digest*, tit. 'Prebend;' Burns, *E. L.*, 88, 90; Rogers, *On Ecclesiastical Law*, tit. 'Dean and Chapter.') [Dean.]

By the 3 & 4 Vic., c. 113, founded on the Report of Commissioners appointed to consider the state of the church with reference to its revenues, very important changes are made relative to cathedral preferment. The statute does not affect existing interests. Its provisions, in general terms, are as follow:—Henceforth all the members of chapters are to be styled canons. Provision is made for the suppression of many existing prebends, the creation of one additional for St. Paul's, and ultimately all cathedral and collegiate churches, as to number of canons, are to be placed upon the following footing:—

Cathedral or Collegiate Church.	No. of Canons.	Cathedral or Collegiate Church.	No. of Canons.
Canterbury	6	Manchester	4
Durham	6	Norwich	4
Ely	6	St. Paul's, London	4
Westminster	6	Peterborough	4
Winchester	5	Ripon	4
Exeter	5	Rochester	4
Bristol	4	Salisbury	4
Carlisle	4	Wells	4
Chester	4	Windsor	4
Chichester	4	Worcester	4
Gloucester	4	York	4
Hereford	4	St. David's	2
Litchfield	4	Llandaff	2
Lincoln	4		

All bishops are authorised to confer honorary canonries, without emolument, to the number of twenty-four in each cathedral church.

No canon is, by virtue of his canonry, for the future to possess any separate estate or income, all of which are to vest in the Ecclesiastical Commissioners appointed by 6 & 7 Wm. IV., c. 77. The profits of the suspended canonries are to be paid to the commissioners, in whom their estates, as well as those of non-residentiary prebendaries, &c., are to vest. The dean of Durham is to receive an average annual income of 3000*l.*; the deans of St. Paul's and Westminster, and the warden of Manchester, of 2000*l.* each. The canons of each of those churches, 1000*l.* The dean of every other cathedral or collegiate church in England, an income of 1000*l.*; of St. David's and Llandaff, 700*l.* The canons of every other cathedral church in England are to have 500*l.*; of St. David's and Llandaff, 350*l.* The separate patronage of members of chapters is to be vested in the respective bishops. Provisions are made as to the exercise of the patronage of chapters. And it is made unlawful for any spiritual person to sell or assign any patronage or presentation belonging to him by right of his office. The minor canons are to be appointed by the chapter.

PREBENDARY ('Prebendarius'), one who has a prebend [Prebend], a canon endowed with land or an advowson or tithe. In right of his prebend, he possessed an estate. He was bound by canon 42 to reside four score and ten days during each year in the church to which he belonged. The time fixed by 3 & 4 Vic., c. 3, is three months. The number of prebendaries varies in different churches. The whole body attached to each, together with the dean, forms a corporation aggregate, called the dean and chapter. Each prebendary, having a distinct estate, is, by virtue of that, a sole corporator, as well as member of the corporation aggregate. The office of the dean and chapter is to consent to the grants, leases, &c. of the bishop. Antiently they formed his council, as they still do nominally. On his death they certify the king of it in chancery, upon which a congé d'elire is issued. During the vacancy, they govern the diocese and guard the spiritualities of it, unless where the archbishop has that right by prescription. Prebendaries were bound by canon 43 to preach in their churches, and in other churches in the diocese, especially those whence their profits proceeded, or to substitute other preachers approved by the bishop. A prebendary could not make a grant, &c., until after installation and induction. [DEAN; CHAPTER.] (*Termes de la Loy*, tit. 'Prebend,' 'Chapter;' *Com. Dig.*, tit. 'Ecclesiastical Persons.')

PRECEDENCE, one of the artificial distinctions among men living in a state of political society. In all countries the great mass of mankind will be of one level, no individual possessing political privileges which do not belong to the rest, except as pertaining to some particular employment in the various ordinary businesses of life in which each individual is engaged. But these give no precedence of one before another; all move on abreast. But above these are certain persons, such as the members of the liberal professions, persons who hold or have held offices in the state, peers, who take precedence of the rest, and who are allowed to do so, if not by any law absolutely promulgated, yet by the constant usages of society. And again, the individuals, who may form perhaps the thousandth part of the whole community, who possess this privilege of precedence, have the precedence amongst each other regulated according to usage, or, in other words, by the precedents established in records of former arrangements. The subject is one to which a good deal of attention has been paid, and it is now only as an incident to the creation of new courts or officers, or in singular positions of the royal family, that difficulties arise. The members of the College of Arms, who are the council of the earl-marshal of England, are usually referred to in questions of precedency; and to them is assigned the arrangement of public processions, as at royal marriages, funerals, coronations, and the like, when it is that questions of this kind come to be considered.

Tables of precedency may be seen in many books, and especially in those called peerages.

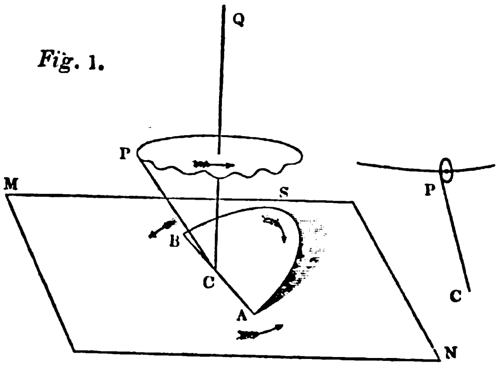
Sometimes the question arises among ambassadors who shall enter a room or depart before another, and great tenacity has at times been manifested in supporting the claims to rank of the state or kingdom represented. In the 'Philoxenis' of Sir John Finet there are some almost ridiculous instances of the struggles made for precedence by ambassadors of the state of Venice in the reign of James I.

PRECESSION AND NUTATION, the abbreviated way of expressing the precession of the equinoxes and the nutation of the earth's axis.

These phenomena should always be considered in connection with the rotation of the earth, of which they really form a part; that is to say, diurnal rotation, precession, and nutation are the motions of the earth about its centre, independently of the motion of that centre along its orbit round the sun. It will assist our comprehension of the subject to suppose the earth's centre a fixed point, the relative motions of the heavenly bodies being adjusted accordingly. [MOTION.]

The rotation of the earth round its axis is visible from hour to hour by the change of place in the stars: the precession and nutation are motions of too slow a nature to be rendered visible, and indeed could hardly be made so unless the ecliptic and equator were visible circles. If such were the case, and if the motions were large enough, the equinoxes, or intersections of the equator and ecliptic, would appear to change place, the equator moving slowly round the ecliptic with a retrograde motion, that is, contrary to the annual course of the sun. The equinoxes would appear to move with a variable motion, sometimes a little faster and sometimes a little slower than the mean motion. At the same time the equator would appear to swing backwards and forwards to and from the ecliptic, turning upon the equinoxes as pivots. Of these motions the average motion of the equinoxes upon the ecliptic is the precession; the alternate acceleration and retardation is one part of the nutation; and the alternate increase and diminution of the angle contained between the two is the other part. It is however common to call the acceleration and retardation of the motion of the equinoxes by the name of the equation of the equinoxes, and to reserve the name of nutation for the motion of the pole which corresponds to it.

Fig. 1.



Let C be the centre of the earth, CP half its axis, P the north pole, and ASB half of the equator. Let MN be part of the plane of the ecliptic, and CQ a line perpendicular to it, pointing therefore to the pole of the ecliptic in the heavens; and let the direction of the diurnal rotation be that of the arrow marked on the equator. If then P were carried uniformly round a circle perpendicular to CQ, so that CP should describe a conical surface, the equinoxes B and A would be carried round in a direction contrary to that of the diurnal motion, and with them the equator BSA, the angle which the equator makes with the ecliptic remaining unaltered. This motion of B and A is the precession. But suppose that instead of P being placed on the circle, it is placed on the circumference of a small oval, which has its centre on the circle. While the centre of the oval moves forward on the circle with the motion of precession, let the pole P move round the oval with a motion much slower than that of the precession. It will then trace out in space an undulating curve, as shown in the principal diagram, and the effect will be an alternate retardation and acceleration of the motion of the equinoxes along the plane of the ecliptic, together with a vibration of the plane of the equator to and from the ecliptic; which are the motions described as constituting the nutation.

The preceding is a description of the effect of any one of the heavenly bodies, theoretically speaking, upon the axis of the earth. The whole precession and nutation is the united effect of the sun, moon, and planets. The effect of the planets however is insensible, except in a slight annual alteration of the plane of the ecliptic, which is mixed up with the precession, and makes it appear a very little smaller than it would be if the system of the sun, moon, and earth were undisturbed by the planetary attraction. The general reader need only attend to the main phenomenon, namely, that the equinox (the point of the heavens at which the sun is at the commencement of spring) moves slowly* backwards along the ecliptic, at the rate of 50¼ seconds per annum, or about 14° in one thousand years. This rate of motion is subject to a very slow increase, which is not perhaps sufficiently well determined to make it worth while to compute exactly the time in which the equinox describes the whole heavens, a period of between twenty-five and twenty-six thousand years.

A good notion of precession may be got from observing the spinning of a top. As long as the axis of the top is not vertical, this axis itself revolves, but much more slowly than the top revolves round its axis. Let the top be supposed to remain with its axis at one angle to the vertical, except only a slight balancing motion to and from the vertical, and let the conical motion of the axis be slightly accelerated and retarded; this will give a complete notion of the phenomena of precession and nutation.

Before proceeding to the mathematical and physical description of these phenomena, we shall show the manner in which they may have an historical and chronological importance. Let the reader take a globe or a map of the stars, he will see that the ecliptic crosses the equator under the tail of one of the Fishes, so that the vernal equinox is nearly in a line with the stars α Andromedæ and γ Pegasi (Alpherat and Algenib). These stars then are invisible at the beginning of the spring, being in the region of the heavens nearest to the sun. Let from twelve to thirteen thousand years elapse, and the slow precessional motion of the equinoctial points will reverse the positions of the equinoxes, so that the above-named stars will be near the meridian at midnight at the commencement of spring, as the stars in the head of Virgo are now. An Aratus of our day would celebrate the brightness of Virgo in the nights of spring, while one of thirteen thousand years hence must choose Pisces for that purpose. The seasons of the year at which different stars begin to be distant enough from the sun to shine brightly is undergoing a gradual alteration. Hesiod, for instance, says that in his time and country Arcturus rose at sunset in sixty days after the winter solstice; Newton calculated that this took place about B.C. 870, which is one of his reasons for supposing that the poet was alive about that time. The phenomenon however is itself rather vague, and Hesiod may be supposed not very exact in his description. It is generally considered that Newton attached too much importance to such data in settling his system of chronology.

---

* It will perhaps be more intelligible to imagine all the stars moving slowly forwards in parallels to the ecliptic, the equinox remaining unchanged.

About two thousand years ago the equinox was twenty-eight degrees more advanced among the signs, and was near the beginning of the constellation Aries. It was about this time that the precession of the equinoxes was discovered by Hipparchus [ASTRONOMY; HIPPARCHUS], and since that time the vernal equinox has preserved the title which it properly held at the time when its motion was discovered, namely, the first point of Aries. Certain astronomical fictitious constellations have been made to move with the equinox, at least until lately; counting from the equinox, the first thirty degrees of the ecliptic have been always called Aries, the second thirty Taurus, and so on. Thus when an astronomer of the middle ages asserts the longitude of a star to be ♎ 18° 22′, he means that it is in 18° 22′ of the astronomical Libra, a constellation supposed to begin at 6×30° or 180° distance from the vernal equinox. An astronomer of our day would say the star's longitude was 198° 22′.

Taking the beginning of the year 1750 as the starting point (as is generally done since the publication of the Mécanique Celeste), and calling t the number of years elapsed, the whole motion of the equinoxes from precession, including the effect of the planetary action on the ecliptic, is

$$50''\cdot176068\ t + 0''\cdot0001221483\ t^2,$$

while the precession in one year is

$$50''\cdot176068 + 0''\cdot0002442966\ t.$$

M. Bessel substitutes 50″·21129 for 50″·176068.

The obliquity of the ecliptic, assumed at 23° 28′ 18″ in 1750, is

$$23^\circ\ 28'18'' - 0''\cdot48368\ t - 0''\cdot00000272295\ t^2;$$

its yearly diminution, arising from the planetary action, independently of nutation, being

$$0''\cdot48368 + 0''\cdot0000054459\ t.$$

M. Bessel takes 23° 28′ 17″·63 for the obliquity in 1750, and uses 0″·457 instead of 0″·48368.

The nutation affects both the place of the equinoxes and the obliquity of the ecliptic. Let the effect upon the former, called the equation of the equinoxes, be E; and that on the latter O. Let ☊ stand for the mean longitude of the moon's ascending node, ⊙ for the sun's true longitude, and ☽ for the moon's true longitude. The formulæ which express E and O are of the following form:

$$E = -A \sin \Omega + B \sin 2\,\Omega - C \sin 2\,\odot - D \sin 2\,\text{☽}$$
$$O = a \cos \Omega - b \cos 2\,\Omega + c \cos 2\,\odot + d \cos 2\,\text{☽}$$

The values of A, a, &c., depending upon the moon's mass as compared with that of the earth (an element which has caused some discussion), have been given in a slightly different manner by different astronomers. We subjoin their values according to Laplace, Brinkley, and Littrow; the two former as cited by Mr. Baily, the latter from Kreil's 'Sammlung der Nothwendigsten Mathematischen Formeln.'

	Laplace.	Brinkley	Littrow.		Laplace.	Brinkley.	Littrow.
A	18″·0377	17″·298	18″·89	a	9″·648	9″·250	10″·11
B	0″·21707	0″·208	. .	b	0″·09423	0″·090	. .
C	1″·13645	1″·255	0″·97	c	0″·49333	0″·545	0″·42
D	0″·21632	0″·207	0″·22	d	0″·0939	0″·090	0″·09

It thus appears that by far the largest part of the effect of the nutation arises from the moon, and depends not upon the place of the planet, but upon that of its node. This node [MOON] performs a complete regressive revolution in about eighteen years and a half, in which time the main effect of nutation goes through all its changes. Bradley, the discoverer of the nutation, found out and assigned the law of its largest term; the remaining ones are due to the theory of gravitation. It took him twenty years of observation, somewhat more than the whole period of the change, to detect the law of the anomaly whose existence he became sensible of immediately after his discovery of aberration had cleared away the largest part of the then unexplained motions of the stars. The discovery was completed and published at the end of 1747. In 1749 appeared the 'Recherches sur la Precession,' &c. of D'Alembert, in which the phenomenon was shown to be the necessary consequence of the moon's attraction upon the earth. Newton had already, in the 'Principia,' given the general explanation of the subject, and had even foretold, without assigning magnitudes, the existence of those terms of nutation which depend upon twice the true longitudes of the sun and moon; but the most important terms, those depending on the moon's node, appear to have been altogether unsuspected by him.

We now come to such a physical explanation of the cause of precession and nutation as can be given without mathematical analysis. On looking at the motion of the equator arising from precession and nutation, we see that it precisely resembles in character some of the alterations which take place in a planet's orbit, the precession answering to the regression of the nodes, the equation of the equinoxes to the variation of that regression, and the remaining part of the nutation, or the variation of the obliquity, to the variation of the inclination to the ecliptic. It was soon seen by Newton, that on the supposition of the mutual attraction of all the particles of matter, the action of the heavenly bodies on the protuberant parts of the earth must produce exactly that sort of effect on the motion of the equator which the disturbing force of the sun, for instance, produces on the moon. He thus explains, firstly, the precession; secondly, that part of the nutation of the inclination which depends upon twice the longitude of the disturbing body. This explanation (prop. 66, corollaries 18-22) is substantially as follows:—

If a sphere in rotation be attracted by another body, the axis of rotation must remain unaltered: for since a plane drawn through any attracting point and the centre of the attracted sphere cuts the sphere into two perfectly similar halves, there is no effect upon the rotation (or tendency to an effect) arising from the attraction upon one half of the sphere which is not destroyed by the tendency to the exactly opposite effect arising from the attraction upon the other half. If then the earth were a perfect sphere, whatever motion of translation the whole sphere might receive, the axis would always remain parallel to its first position, and there would be neither precession nor nutation. Again, let the earth be a solid of revolution, protuberant for example at the equator, as is the case, and let an attracting point be situated in the plane of the equator; the symmetry just alluded to still exists, and the result is the same. But if an attracting point be not situated in the plane of the equator, the plane passing through the attracting point and the centre divides the spheroid into parts which, though equal, are no longer similarly situated with respect to the attracting point. The alteration of the axis which would take place if one half only were attracted, is no longer counterbalanced by the attraction on the other half: the direction of the axis is therefore continually changed.

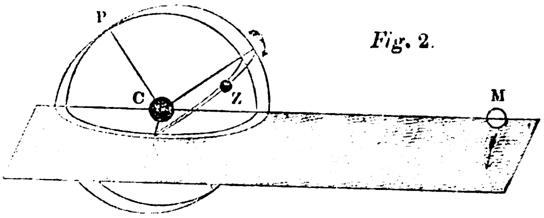


Fig. 2.

To get a specific idea of the nature of the change, first suppose the spherical part of the earth only to exist, the protuberance being removed; and the solidity of the sphere still remaining, let all its matter be supposed to be removed to the centre at C (*Fig.* 2). The diagram shows the spheroid of the earth, distinguishing the inscribed sphere from the protuberant part; the solidity of both parts is supposed to remain, but the matter of the internal sphere is removed to

C, that of the protuberant part is not yet introduced: M is the attracting body, and the plane of its orbit is given, while the directions of the earth's rotation and of M's orbital motion are denoted by arrows. At present M produces no effect on the rotation; now let a small mass of matter be affixed to the equator at Z, which will therefore move round the mass C in and with the equator. The consequence will be [GRAVITATION, section viii., vol. xi., p. 393], that the node of this orbit (the equinox A) will regress, or move in the direction opposite to that of the arrows, while the inclination of the orbit will alternately increase and diminish, being greatest when the line C M passes through one of the equinoxes. If we put such satellites all round the equator, the effect will not be altered in quality, but increased in magnitude; and if we fill up all the protuberant part of the spheroid, the effect will still be of the same sort, though further increased in magnitude. The effect of the parts of the protuberance nearer to the pole is, for a given mass, less than that of the parts near the equator. Finally, if we restore the mass of the internal sphere to its proper place, the effect will be less than before; for since no motion of the protuberant part can take place without one of the whole sphere, and since rotation is more difficult to produce, the greater the distance of the masses moved from the axis, the distribution of the mass at C over all parts of the sphere will render M less efficient in the alteration of the direction of the axis. Thus it appears that the phenomena of precession and nutation *may* arise from the consideration of the protuberant part of the spheroid as a fixed satellite to the internal part; but the proof that the precession and nutation *do* so arise consists in taking a strict mathematical process, investigating the precession and nutation in quantity as well as quality, and showing that the results agree with those of observation.

But, as before noticed, the largest part of the nutation depends, not on the place of the moon in its orbit, but on the position of the orbit, that is, on the node of the orbit. Supposing the moon's orbit circular, imagine the mass of the moon to be distributed in a ring all round its orbit. If this ring were simply to revolve in its own plane, the precession and nutation produced by it in the earth, though materially altered in quantity, would be of the same sort as before, and in both cases very small. But suppose the ring to shift its position, as does the moon's orbit, its nodes slowly regressing at the rate of a revolution in eighteen years. This shifting of the position of the ring will of course produce an alteration in the phenomena, and the substitution of the moon revolving in a shifting orbit in place of this ring must now be made. That the effect of the change of the orbit should be greater than that of the planet itself in a fixed orbit ought not to be surprising, since there is no à priori reason why it should be either greater or less.

Throughout the solar system there is no action of one planet upon a second, without a corresponding action of the second upon the first. The protuberance of the earth, by which the planets produce precession and nutation, attracts those planets, and slightly varies their motion. In the case of the moon, sensible irregularities, both in longitude and latitude, amounting at the maximum to about 7″ in each, were found by Mayer, before Laplace showed them to be the consequences of the earth's protuberance. These inequalities may be made the means of calculating the amount of that protuberance, or, as it is technically called, the ellipticity of the earth: and it is a fact not a little remarkable, that the amount of this ellipticity, as calculated from its effect upon the moon's longitude, agrees with the same, as calculated from its latitude, better than actual measurements of the earth generally agree with one another, while both agree very nearly with the best of the latter. This sort of result had been anticipated as to quality by Newton, who showed that the motion of the equinoxes, being retrograde, proves the earth to be protuberant at the *equator*, and that if it had been protuberant at the *poles* (as many then thought was the case), the precession would have been in the contrary direction.

PREDESTINATION is the decree of God by which he has from all eternity predetermined whatsoever shall come to pass. That the whole universe is governed by a fixed plan, and that all events are tending to the accomplishment of certain objects, is a necessary result of the infinite foreknowledge of God, and of his character as the being who 'created all things, and for whose pleasure they both are and were created.' (*Rev.* iv., 11.) To suppose that any events can result either from a necessity or from a chance opposed to the divine will is evidently to assume a limit to the power of the deity. Some theologians have indeed maintained that though God is possessed of the attribute of infinite prescience, yet with respect to some objects he voluntarily forbears to exercise that attribute. But to suppose a voluntary limitation of an infinite power is both absurd in itself and derogatory from the divine character, since for God to limit any of his attributes is for him to make himself less than perfect, and by setting bounds to his knowledge he must lessen his wisdom, and thereby impair his character as the ruler of the universe. This notion also involves another absurdity; for if God wills to be ignorant of anything, it must be because there is something in that thing which it is undesirable to know; and therefore the nature of the thing must be known to God before he can determine not to know it.

In its relation to the present powers and the future state of men, the doctrine of predestination has been the subject of the most violent and entangled controversies. An account of the extreme views entertained on the one hand by Augustin, Calvin, and their followers, and on the other by the Pelagians and Arminians, has been given in the articles ELECTION and PELAGIANISM; but the opinions of Dr. Edward Williams, which, under the name of Modern or Moderate Calvinism, are now generally held by Calvinistic divines, have not been sufficiently noticed in the article Election. Dr. Williams thus defines the predestination of the modern Calvinists:—'What we maintain is, that all mankind are in a state of guilt and sinful imbecility; that God foresaw this from eternity; that he therefore predestinated an adequate remedy in the sacrifice of Christ; that this should be announced to men as commensurate to the evil. We further maintain that there was not in the present state of man any ground of certainty that any one, without preventing gracious influence, would avail himself of the proposed remedy; and therefore that God predestinated, under the direction of infinite wisdom, to influence the hearts of some, that is, those who are finally glorified, to repent, believe, obey, and persevere in a holy course, as the way to everlasting happiness. Heaven is the end, but holy obedience is the way to it. We hold no predestination that separates the end and the means. We do not presume to conjecture à priori who are predestinated to eternal life; but rather infer from the imbecility of man, that if any one is penitent, faithful, diligent, persevering, and finally glorified, these great effects are from the special and distinguishing energy of God; and that whatever he does in time he purposed to do from eternity. This is our predestination.' (Dr. Williams's *Defence of Modern Calvinism*, p. 202.) To the objection that it is inconsistent with the justice of God to decree that some only, out of the whole human race, should be saved, it is replied, that all deserve damnation; and therefore while it is an act of sovereign mercy to save some, it is an act of strict justice to leave the rest to perish.

The greatest difficulty in this doctrine is the supposition, maintained equally by Calvin and the Anti-Calvinists, that election and reprobation are inseparable: that if God has destined some to eternal happiness, it follows as a necessary consequence, that he has destined the rest of our race to eternal damnation. This consequence is denied by the modern Calvinists. 'It takes for granted,' says Dr. Williams, 'what never can be proved, that non-election implies a decree. Non-election is a negative idea, not electing; but to decree a negation is as absurd as to decree nothing, or to decree not to decree. The notion of decreeing to permit involves the same absurdity; for to permit, in this connection, is not to hinder, but to decree not to hinder is the same thing as to decree to do nothing; or, as before, to decree not to decree. The fallacy consists in the supposition that non-election is a positive idea, and therefore requires a positive determination by way of decree.' (Ibid., p. 206.) The same objection holds against the modified form of the doctrine of reprobation, which is called *preterition*, namely, that God decreed to choose some and to pass by the others. It should be carefully observed that the doctrine of election involves no idea of any who are seeking after salvation being denied, repulsed, or hindered.

Another objection to the doctrine of predestination is, that it makes evil to be the result of a divine decree. This again the modern Calvinists deny. They maintain that the limitation of man's powers is not the result of a decree, but a quality which, by the nature of things, is inherent to every created being; and that therefore the defects, and, among others, the sinful defects, which are the consequences of this limitation, do not result from a divine decree.

To the objection that predestination is inconsistent with free will, it is answered, that the actions, even of a free will, must be determined by some cause, either efficient or deficient; and that God foreknows the deficiencies which are the causes of all the evil determinations of the human will, while all its good determinations proceed from himself, as the source of all good.

(Dr. Williams's *Defence of Modern Calvinism*, and *Essay on the Equity of the Divine Government and the Sovereignty of Divine Grace;* Dr. Payne's *Lectures on Divine Sovereignty, Election, &c.*)

PREDICABLES. The term predicable (*κατηγορικόν*, *prædicabile*) is applied in logic to general names, considered as capable of being the predicates of propositions. [On Predication, see ORGANON, p. 3.] The classes of predicables usually recognised by logicians are five, viz. 1, Genus; 2, Species; 3, Differentia; 4, Proprium; 5, Accidens, which Latin names are translated from the Greek, 1, *γένος*; 2, *εἶδος*; 3, *διαφορά*; 4, *ἴδιον*; 5, *συμβεβηκός*.

The five-fold classification of the predicables does not occur in Aristotle's 'Organon,' or any other of his extant writings; and it probably did not occur in any of his lost writings. The word *γένος* is often used by Aristotle to signify a class: we do not however recollect any instance of the use of the word *εἶδος* in the sense of a logical species in his writings. In his 'Nicomachean Ethics,' b. i., c. 4, he applies the word *εἶδος* to the ideas (or supposed archetypal forms of general notions) which were imagined by Plato. The word *συμβεβηκὸς* (or *κατὰ συμβεβηκὸς*) is often used by Aristotle to signify that which is contingent or accidental, in opposition to that which is necessary (*ἀναγκαῖον*).

The earliest work in which the received classification of the predicables occurs, is an 'Introduction to Aristotle's Categories,' written by Porphyry of Tyre, the well-known heathen philosopher of the third century (born 233 A.D.) and the author of other extant works. (Printed in Bekker's 'Aristotle,' vol. iv., p. 1-6; see also the other excerpts to p. 21.) Porphyry states, at the outset of this treatise, that a knowledge of the five predicables is necessary for the proper explanation of Aristotle's work on the categories; and he therefore addresses to a certain Chrysaorius a popular account of them, derived from the antient philosophers, especially the Peripatetics. (Concerning Chrysaorius, see David, ib., p. 18, b. 16.) The five predicables (*αἱ πέντε φωναί*, as they were originally styled) are not however mentioned in Aristotle's work on the categories, as is incorrectly stated in Hermeias, ib., p. 10, b. 14; and it is probable that the 'antient philosophers' alluded to by Porphyry were of considerably later date than Aristotle. An abridgement of Porphyry's treatise on the predicables, by Michael Psellus, of Constantinople, who lived in the eleventh century, has also been preserved; and it is reprinted in the beginning of the small Oxford edition of 'Excerpts from Aristotle's Organon' (Clarendon press, 1802). Concerning Michael Psellus, see Allatius 'De Psellis,' in Fabric. 'Bibl. Gr.,' vol. v.

From this treatise the classification and explanation of the predicables have passed into the various treatises of the Aristotelian logic, and have been repeated in them with some variations and developments, but with little substantial change, up to the present day. (Whateley's *Logic*, part i.)

It appears to us that the explanation of the predicables which is usually given in treatises on logic is infected with realism; that is to say, it implies that there is something in nature, besides individual things, corresponding with general notions. We shall therefore lay before the reader a brief statement of the definitions of the five classes of predicables which seem to us to be the most convenient. The narrowness of the space at our command prevents us from pointing out the differences between these definitions and the definitions which are usually received, and our reasons for preferring the former to the latter.

The name of any proposed class may be called the *species;* for example, man.

The name of any class including this class may be called a *genus*, with reference to the species; for example, animal, with reference to man.

The two preceding heads of predicables are names of classes; the remaining three are names of attributes or qualities.

Differentia is the name of any attribute which belongs universally to the species, and to it alone. For example, the power of ameliorating his condition in successive generations, and the power of using language, as belonging to man. A logical *definition* is composed of the *genus* and the *differentia;* thus, according to the explanation of differentia which has been just given, man would be defined logically by saying that he is 'an animal which possesses the power of using language.'

Proprium is the name of any attribute which belongs universally to the species, but not to it alone. For example, sensation, the power of articulate speech, or memory, as belonging to man.

Accidens is the name of any attribute which may or may not belong to any individual of the species. For example, the colour of the skin in man.

There being nothing external which corresponds to general notions, the principles by which classes may be formed may be chosen at pleasure, according to the purpose which the classifier has in view. On this subject, see further in ABSTRACTION and GENUS.

The introduction of the theory of realism into the received explanation of predicables appears to have arisen from an identification of genus and species with matter and form.

It was thought that the material or essential substratum, or the substance of a thing (that part which, according to the Catholic theology, is changed in the process of transubstantiation), is the genus; and that the outward form or appearance is the species. See a distinct statement to this effect in Porphyrius, p. 3, b. 38, ed. Bekker. It is to be observed, that the same word is used both in Greek and Latin to signify both logical species and form (*εἶδος*, species).

(On the predicables, see some remarks in an able article in the *Westminster Review*, No. 17; and a pamphlet, published at Oxford in 1829, entitled *An Examination of some Passages in Dr. Whateley's Elements of Logic.*)

PREDICAMENTS, or CATEGORIES, are certain heads of general notions or propositions, an inquiry into which is contained in a treatise by Aristotle which stands first in the extant series of his logical writings. [ORGANON, p. 9.] The following are the predicaments, or categories, as classified by Aristotle:—1, substance (*οὐσία*); 2, quantity (*τὸ ποσόν*); 3, relation (*τὰ πρός τι*); 4, quality (*ποιότης*); 5, opposition (*τὰ ἀντικείμενα*); 6, priority (*τὸ πρότερον*); 7, simultaneity (*τὸ ἅμα*); 8, motion (*κίνησις*).

The most important part of Aristotle's treatise on categories is that which relates to *οὐσία*, or substance; since it contains a discussion (and tolerably correct explanation) of the origin of general notions. It proves that Aristotle did not adopt the theory of realism, although realistic expressions and tendencies may be occasionally discerned in his writings. According to modern usage, the subjects discussed in Aristotle's categories would belong to metaphysical rather than logical science.

A copious and accurate abridgement of Aristotle's treatise on the categories may be found in Barthélemy Saint-Hilaire's 'Logique d'Aristote,' tom. i., p. 140-82. See also Ritter's *Geschichte der Philosophie*, vol. iii., p. 76.

PREDICATE. [ORGANON.]

PRE'FET, PREFECT. [DEPARTMENT.]

PREFIX. [LANGUAGE.]

PREHNITE, a mineral which occurs crystallized and massive. Primary form a right rhombic prism. Cleavage easy parallel to the base of the primary form, and less so in the direction of the lateral faces. Fracture uneven Hardness, scratches glass easily. Becomes electric by heat. Colour white, grey, and various shades of green and greenish yellow. Lustre vitreous. Transparent, translucent. Specific gravity 2·926. The variety which occurs in small thin crystals is called *Koupholite*. The crystals of this substance have a remarkable tendency to exhibit rounded faces.

Massive varieties: botryoidal, globular, and stalactitic, structure broad fibrous; amorphous, structure granular, compact, with rough surfaces. It occurs also in rolled masses.

Before the blow-pipe it is converted into a white scoria, and fuses into a compact globule; with borax it readily becomes a clear glass.

This mineral was first found at the Cape of Good Hope; it has since been met with in many places in different quarters of the globe, as Scotland, Cornwall, France, &c. Koupholite occurs at Barèges, department des Hautes-

Pyrénées. The annexed analyses of Koupholite are by Vauquelin (1) and by Laugier (2):—

	(1)	(2)
Silica	48	42·50
Alumina	24	28·50
Lime	23	20·40
Oxide of iron	4	3
Potash and soda	—	0·75
Water	—	2
	99	97·15

PRELATE (etymologically from *præ* and *latus*), a person *preferred* or advanced before another; but it is confined to a particular species of preferment or advancement, namely, that amongst the clergy, and it is applied to those only among them who have attained the very highest dignity, that of bishop or archbishop, to which we may add *patriarch*, in such churches as have an officer so denominated. The word prelate has however in antient times been applied to simple priests, members of the clerical body in general.

PRELUDE (*Præludium*, a preamble), a brief introduction to a piece of (most commonly) piano-forte music; a few chords, or a flourish, to prepare the hand of the player, and draw the attention of the auditors to what is to follow. A prelude is, or is supposed to be, an extemporaneous effusion, and as such is no bad test of the musical knowledge of the performer.

PREMISES. [ORGANON.]

PRE'MIUM (in the sense in which it is used in the article BOUNTY) is a reward given out of the public revenue to encourage manufactures or other branches of industry; but prizes given by agricultural and other societies are in reality the same thing as premiums. Premiums encourage and reward competition; but when it is proposed to foster any new art by liberal premiums, there is less certainty of an interest thus sustained establishing itself upon the only natural foundation—that which arises from the encouragement of the public; and premiums then fall under the same objections as bounties. These objections are inseparable from a system of bounties, but the judicious distribution of premiums may occasionally be attended with advantage. Adam Smith says of premiums that 'by encouraging extraordinary dexterity and ingenuity, they serve to keep up the emulation of the workmen actually employed in those respective occupations, and are not considerable enough to turn towards any one of them a greater share of the capital of the country than what would go to it of its own accord. Their tendency is not to overturn the natural balance of employments, but to render the work which is done in each as perfect and complete as possible. The expense of premiums, besides, is very trifling; that of bounties very great.' (*Wealth of Nations*, book iv., chap. 5.)

PREMNA, a genus of plants of the natural family of Verbenaceæ, which is characterised by a cup-shaped calyx, a 5-cleft bilabiate corolla. Stamens 4, didynamous. Drupe pea-shaped, with a four-celled nut. The species consist of shrubs and small trees, which are indigenous in Asia and New Holland, having opposite leaves, inflorescence in terminal cymes, with small flowers.

The majority of the species are remarkable for the fetid odour of their leaves, though those of P. cordifolia are somewhat fragrant, and those of P. esculenta are employed as diet by the natives of Chittagong. P. integrifolia has roots of a burning taste, with leaves of a hircine odour. The leaves, applied to the head, are said to cure headache, and a decoction of the roots is employed as a stimulant in fevers, flatulence, &c. P. latifolia has wood of a white colour and firm texture, employed for various economical purposes, in which it agrees in character with the teak tree, Gmelina arborea, and others which belong to the same natural family.

PREMONSTRATENSIAN ORDER. The Premonstratensians were canons who lived according to the rule of St. Austin, as reformed by St. Norbert, afterwards archbishop of Magdeburg, who set up this regulation about A.D. 1120, at Premonstratum in the diocese of Laon in Picardy, a place so called because pointed out, as it was said, by the blessed Virgin to be the head of this reformed order.

These canons were also called *White Canons* from their habit, which was a white cassock with a rochet over it, a long white cloak, and white caps. They were brought into England shortly after A.D. 1140, and settled first at Newhouse in Lincolnshire. They had in England a conservator of their privileges, but were nevertheless often visited by their superiors of Premonstre, who raised great contributions out of them, as the generals or foreign heads of the Cluniacs or Cistercians also did from their order, till restrained from it by the parliament of Carlisle, in the last year of Edward I., A.D. 1307. This statute did not restrain the foreign heads from visiting their charge in England, governing their monks, or exercising the discipline of their order, provided they carried no money away with them. So that the religious of this order in England continued under the jurisdiction of the abbot of Premonstre and the general chapter of the order till A.D. 1512, when they were exempted from it by a bull of Pope Julius II., confirmed by King Henry VIII., when the superiority of all the houses of this order in England and Wales was given to the abbot of Welbeck in Nottinghamshire. Tanner reckoned about thirty-five houses of this order in England.

(Tanner, *Notit. Monast.*, pref., p. xi.; Dugd., *Mon. Angl.*, new ed., vol. vi., p. 856.)

PREPOSITIONS are certain words which express a relation between different things. All words may be divided into notional and relational. [NOTION, NOTIONAL.] Notional words are those which express notions, and which are objects of the understanding. Relational words are those which merely express a relation between the different things which are expressed by notional words. Thus, in 'he went *to* town,' 'he walked *with* his friend,' the words *to* and *with* are relational words, that is, they connect the notions of 'he went' and 'he walked' respectively with the notions of 'town' and 'friend.'

Harris defines a preposition 'to be a part of speech devoid itself of signification, but so formed as to unite two words that are significant, and that refuse to coalesce or unite of themselves.' This definition has been attacked by Horne Tooke, who considers it absurd to imagine that men, in the formation of any language, would invent words without some meaning, and to which singly they attached no determinate idea, and he accordingly endeavours to show that every preposition was originally a verb or a noun. To a certain extent however both these writers are correct, since, according to Harris, prepositions are usually only used to unite words that are in themselves significant, that is, they are only relational words; but, at the same time, there can be no doubt that Horne Tooke is right in contending that prepositions were originally significant, since all words which now merely express relations appear to have been originally notional words.

Prepositions are so called because they are *preposed* or prefixed to the words with which they are connected; but the name is an unfortunate one, since they are sometimes *postponed* or placed after such words, as in *wherewith*, *wherein*, *wherefrom*, *thereby*, &c. In languages like our own, which have hardly any inflections, the relation which one thing bears to another can only be expressed by means of prepositions; but in languages which possess inflections, like the Latin and Greek, the same relation may frequently be expressed by means of cases, which are in fact prepositions placed at the end of nouns. Thus, in the expression 'the son *of* the king,' we express the relation between 'son' and 'king' by the preposition 'of;' while in Latin the same relation is expressed by *is* placed after the Latin word for king, *filius reg-is*. But as the meaning of these case-endings was not always definite enough, it became customary to mark the relation more precisely by prefixing certain words, as in our own language. The case-endings however were not dropped; so that in such expressions as *ad urb-em*, *cum reg-e*, *pro reg-e*, the noun may be said to have two words to mark relation, one placed before and the other after it.

The number of prepositions differs, as might be expected, in different languages. The Greek grammarians admit only eighteen, the Latin about fifty. In English the following words are usually considered as prepositions:—Above; about; after; against; among, amongst; amid, amidst; around, round; at; between, betwixt; beyond; before; behind; beneath; below; beside; by; down; for; from; in, into; near, nigh; of; off; over; on, upon; since; through, throughout; till, until; to, unto; toward, towards; under, underneath; up; with; within; without.

Besides these prepositions, there are in English, Latin, Greek, and many other languages certain particles never found singly, or uncompounded, and which are therefore called inseparable prepositions, as in English *be, for, fore, mis*, &c., which occur in such words as *be-stir, be-speak; for-bid, for-sake; fore-see, fore-know; mis-take, mis-deed*, &c.

PREROGATIVE, a word descended to us from the times of the Romans, or, rather, adopted from their language, to denote a certain power in the constitution of monarchical states. Its etymology is obvious, though the formation is not perhaps quite accordant with the analogies. *Præ* and *rogo* would seem to give the sense of precedence in asking, while prerogative means precedence in being asked, the right of having the consent first obtained of the party in whom the prerogative is vested, before any change shall be made in the matters comprehended within the prerogative. The term is confined to cases of dignity, to things indeed which affect the common interest when men are bound together in a political state; and though we might speak, as indeed men sometimes do, of the prerogative of the House of Lords, or the prerogative of the House of Commons, or even of the prerogative of the people, it is more usual to regard the word as belonging to the right which the king possesses of being consulted, and his consent obtained, in whatever concerns the business of the nation.

Thus the consent of the king (or queen regnant) must be first obtained before any new law can be made, or any change in the laws at present existing, and this appears to be prerogative in its purest state, and, indeed, in its only state of absolute purity. Other things which are now understood to be comprehended under the term prerogative, are only accretions to this the true prerogative, or things which have naturally shot forth out of it: unless we choose to take a view of the whole subject which shall take it wholly out of the scope of the etymological sense, and regard, as indeed many do, the word prerogative as standing to indicate the primordial and original power of any prince, the king of England for instance, which has been from time to time reduced and confined by the resistance, passive or active, of the subject. However the term may be chosen or applied, it now denotes not only the privilege of being consulted in any intended change of the law, and the consent obtained, but the right of making war or peace, of laying embargos, of commissioning officers in the army and navy, of sending and receiving ambassadors, of making treaties, of bestowing honours, conferring rank, and creating peers. To these are to be added the regulation of the coinage and of weights and measures; the pardoning of offenders, which is sometimes called the exercise of the prerogative of mercy; the calling, proroguing, and dissolving parliament, in which however the king's prerogative has been restrained by positive enactments; and, lastly, various rights which the king enjoys in respect of his position as head of the church. All these things the king (queen) does by his prerogative, his own sole will, without any application to parliament, or to any court or council whatever, though members of the Privy Council, those particularly who form what is called the Cabinet Council, or the ministers, are supposed to advise the king in the exercise of his prerogative, and are sometimes made answerable by parliament for the injudicious or dangerous exercise of it. Theoretically however and nominally, these are prerogatives of the king himself—rights inherent in him in virtue of his office, as much his as the subject has certain rights belonging to him, either as a member of the great community of Englishmen, or as belonging to some particular section to which he belongs, or to some particular office in which he is placed. In the mutual respect of each, and the forbearance of each to encroach on the rights or prerogatives belonging to each other, lies the balance of the English constitution; and out of it arises security to all, and the enjoyment of the blessings which belong to a well-ordered political community. When evils are perceived, when the subject claims rights which are incompatible with wholesome government, or when the king claims rights as falling within the scope of any part of his prerogative which are opposed to the common good, there are remedial powers in the constitution which bring things right; and it is one of the most important functions of the two houses of parliament to see to this.

PREROGATIVE COURT, a court held by each of the archbishops (or their officials) of England and Ireland, by virtue of his prerogative, for the purpose of trying the validity of wills, registering them, and granting probate or administration. Its jurisdiction attaches where one dies possessed of bona notabilia, that is, of goods to the value of 5*l.* (except in the diocese of London, where it is 10*l.*) in one diocese or peculiar, and also goods, altogether of the same amount, in some other diocese or dioceses, peculiar or peculiars, within the same province; or where one, not being on a journey, dies in one diocese or peculiar, possessed of goods of that amount in another diocese within the same province. A peculiar is a district exempt from the jurisdiction of the ordinary of the diocese wherein it lies. By means of the Prerogative Court, one administration becomes sufficient; and the inconvenience and uncertainty of taking out administration in various dioceses, &c. are avoided. Where a person dies out of a province, leaving bona notabilia in one of its dioceses exclusively, the prerogative and diocesan courts have concurrent jurisdiction. A probate of the will of a bishop must in all cases be prerogative. A prerogative probate granted where there are not bona notabilia in several dioceses, &c., is only voidable; but a diocesan probate, where there are, is absolutely void. (4 *Inst.*, 335 Williams *On Executors, &c.*)

PRESBURG, *Posonium* (in Hungarian, *Posony*), once the capital of Hungary, is situated on the north bank of the Danube, in 48° 8′ N. lat. and 17° 10′ 45″ E. long. It is built on a hill of moderate height, commanding a fine view over an extensive plain watered by the Danube, the horizon being open in every direction except towards the north-west, where it is intercepted by distant mountains. The Danube is here 130 toises wide, and is crossed by a bridge of boats 365 paces in length, which was substituted in 1825 for the flying-bridge. The fortifications have been demolished, and the suburbs are no longer separated from the city. It appears to have existed in the time of the Romans, or at least under the great Moravian kingdom which the Maygars contributed to overthrow. It was chiefly peopled by German colonists, and was an important frontier fortress against the Germans and Bohemians. It suffered severely in the successive wars, as well with those nations as with the Tartars (1241) and the Turks. In 1446, Ofen having fallen into the hands of the Turks, Presburg was declared the capital of the kingdom, and the diets were held here till the year 1784, when Joseph II. decided that the viceroy and palatine, with the high officers of government, should reside at Ofen, as a more central situation. The emperor is however still crowned here as king of Hungary. Presburg, which was formerly not only the handsomest, but the most important and most populous city in the kingdom, is now far surpassed in all respects by Pesth, in political importance by Ofen, and in population by Debreczyn. Including the suburb of Blumenthal, with the Zuckermandel and the Schlossberg (which belong to Count Palffy, and are not properly parts of the city, though commonly reckoned as such), it has a population of 38,800 inhabitants, of whom 8000 are Protestants and 2700 Jews. The trade of the city is neither flourishing nor increasing: the navigation of the Danube has not afforded much advantage, but it is expected that the increasing number of steam-boats that navigate the river from Vienna to its mouth, and thence to Constantinople, will prove very beneficial to Presburg. The principal buildings are—the cathedral, in which the kings of Hungary are crowned; the county-hall, the antient senate-house, the archiepiscopal palace, the palace of prince Grassalkovics, and the theatre. Among the public institutions are a Catholic academy, with a library of 12,000 volumes; a Protestant lyceum, a Catholic gymnasium, a royal national model school, several other schools (one of them an infant-school), an hospital, and the great library of Count Appony, of 50,000 volumes, three monks' convents, and two nunneries. On a hill out of the city, 439 feet above the level of the Danube, are the remains of the royal palace, which, after having been long used as a barracks, was burnt down in 1811, and has not been restored. The German language and manners prevail, together with the Slavonian. There is much agreeable society at Presburg, in consequence of the many magnates and nobles, of officers living on their pensions, of clergy, and professors. The chapter, consisting of twelve canons, is antient, and well endowed. There are various manufactures of woollens, silk, tobacco, snuff, oil, rosoglio, and some tanneries, but all on a small scale. The environs of Presburg are very agreeable, and there are numerous places of amusement and public resort. One of the remarkable spots is an artificial hill, or mound, of inconsiderable height, to which the king of Hungary rides after his coronation, and brandishes a naked sword towards the four cardinal points, to intimate that he will defend the kingdom against its enemies, from whatever quarter they may come.

(Jenny, *Handbuch;* J. von Thiele, *Das Königreich Ungarie;* Blumenbach, *Gemälde der Oesterreichen Monarchie;* Hassel; Stein; &c.)

PRESBYTERIANS (πρεσϐύτερος, an elder) are professors of the Christian religion who believe that there is no order in the church, as established by Christ and his Apostles, superior to that of Presbyters; that all ministers, being ambassadors of Christ, are equal by commission; that Presbyter or Elder, and Bishop, are only different names for the same person; and that Deacons are laymen whose office is chiefly to take care of the poor. A Presbytery (πρεσϐυτέριον) they regard as a society of clerical and lay Presbyters, or, as they usually call them, Ministers and lay Elders. In support of these opinions they allege several passages of the New Testament. They affirm that the primitive form of church government was universally Presbyterian, and that this form, having, after the time of the Apostles, been supplanted by Episcopacy, was restored in some parts of Europe after the Reformation had begun.

The most noted Presbyterian Church of the present day is that of Scotland, which is called the Kirk, of which we shall here furnish a short account.

Presbyterianism was introduced into Scotland about 1560. Under Calvin's direction this discipline had already been put into operation at Geneva, whence it was brought by John Knox into his native land, though not in precisely the same form as that which was afterwards given to it. King James I., who had been a Presbyterian in Scotland, and who embraced Episcopacy upon coming to the English throne, made Episcopacy, nominally at least, the religion of Scotland. In the reign of Charles I. Presbyterianism regained the ascendency, but Episcopacy was once more declared the established religion at the restoration of Charles II. At the Revolution in 1688, Presbyterianism was reestablished in Scotland by authority of Parliament, and thus it has continued to the present time.

The constitution of Presbyterianism in Scotland is as follows:—The Kirk Session, consisting of the minister and lay or ruling elders of a parish or congregation, is the lowest court of judicature, the minister being, ex officio, the moderator or chairman. This Kirk Session has power to cite before it any members of the congregation, and to examine, instruct, rebuke, admonish, and suspend them from the Eucharist. The Presbytery is next in authority, and consists of all the ministers of a certain district, and one ruling elder from each parish, who is chosen half-yearly. At the meeting of a Presbytery, a moderator is chosen out of the ministers. There are 69 Presbyteries, each consisting of parishes in number not more than 24 nor fewer than 12. The Provincial Synods, of which there are 15, meet twice in the year, and are composed of the Presbyteries within the provinces which give name to the Synods. The highest authority is the General Assembly, which meets annually. This is composed of delegates from each Presbytery, from every royal borough, and from each of the Scotch universities, and the president is a nobleman who represents the person of the king, and who is called the Lord High Commissioner. In all matters of dispute the appeal lies from the Kirk Session to the Presbytery, from this to the Provincial Synod, and from the Provincial Synod to the General Assembly. Persons are appointed ministers by the laying on of the hands of the Presbytery. The maintenance of the clergy is regulated by the state, and they are nominated to livings by patrons. The Kirk has no Liturgy, no altar, and no instrumental music. Its doctrine is Calvinistic. At the Revolution the Westminster Confession was appointed the standard of the national faith, and it was enacted that no person should be admitted or continued a minister or preacher in this church, without subscribing to this Confession of Faith as his faith. By the Act of Union in 1707, the same subscription is required of all professors, principals, regents, masters, and others bearing office in any of the four universities of Scotland.

There are however many Presbyterians in Scotland who do not belong to the national establishment, and who are called Seceders. But they maintain the same articles of faith as the members of the Kirk, and hold Associate Synods for regulating matters of discipline. They secede, because they suppose the Kirk to be in a state not consistent with its acknowledged principles.

The first Presbyterian congregation in England was formed at Wandsworth, near London, in 1572. In the reign of Charles I., 1645, it was proposed, in the treaty of Uxbridge, to make the Established Church of England Presbyterian, and the proposition was carried into effect by way of trial in 1646. In 1649 the Presbyterian discipline was sanctioned by parliament, and the Established Church was Presbyterian till Episcopacy was restored with the restoration of Charles II. in 1660.

There are still congregations in England called Presbyterian; but in both doctrine and discipline they differ materially from the Scottish Presbyterians. 'The English Presbyterians, as they are called,' says one of their writers, 'adopt nearly the same mode of church government with the Independents. Their chief difference from the Independents is, that they are less attached to Calvinism, and consequently admit a greater latitude of religious sentiment.'

PRESCOT. [Lancashire.]

PRESCRIPTION. 'No custome is to bee allowed, but such custome as hath been used by title of prescription, that is to say, from time out of mind. But divers opinions have been of time out of mind, &c. and of title of prescription, which is all one in the law.' (Litt., § 170.) According to this passage, 'time out of mind,' and 'prescription,' which are the same thing in law, are essential to custom: another essential to custom is usage. But there is a claim or title which is specially called prescription, and which is like custom so far as it has the inseparable incidents of time and usage; but it differs from custom in the manner in which it is pleaded, which difference shows the difference of the right. This claim is called prescription, because the plaintiff or defendant who makes it 'prescribeth that,' &c.; stating, after the word 'prescribeth,' the nature of his claim.

The following is an example of a prescription (Co. Litt., 114, a):—'I S., seised of the manor of D. in fee, prescribeth thus: that I. S., his ancestors, and all whose estate he hath in the sayd manor, had and used to have common of pasture time of mind in such a place, &c., being the land of some other, &c., as pertaining to the same manor.' The claim of a copyholder of a manor for common of pasture in the manor, alleges a custom time out of mind within the same manor, by which all the copyholders of the manor have had and used common of pasture in it. The claim by prescription then is properly a claim of a determinate person: the claim by custom, as opposed to prescription, is local, and applies to a certain place, and to many persons, and perhaps, it may be added, to an indeterminate number, as the inhabitants of a parish. The following definition of prescription appears to be both sufficiently comprehensive and exact:—'Prescription is when a man claimeth any thing for that he, his ancestors, or predecessors, or they whose estate he hath, have had or used any thing all the time whereof no memory is to the contrary.' (*T. de la Ley.*) From this definition it follows that prescription may be a claim of a person as the heir of his ancestors, or by a corporation as representing their predecessors, or by a person who holds an office or place in which there is perpetual succession; or by a man in right of an estate which he holds. It is said that certain persons, attorneys for instance, may prescribe that they and all attorneys of the same court have certain privileges; it seems indifferent whether this is called prescription or custom, but it is more consistent with the old definitions to call it prescription, since it is not a local usage, and it is by or on behalf of a determinate number of persons, that is, all the attorneys of a particular court. It is also said that parishioners may prescribe in a matter of easement, as a way to a church-yard, but not for a profit out of land: such a prescription however is not contained within the above definition, and is in all respects more properly a custom.

It is essential to prescription (subject to the limitations hereinafter mentioned) that the usage of the thing claimed should have been time out of mind, continuous, and peaceable. 'Time out of mind' means, that there must be no evidence of non-usage or of interruption inconsistent with the claim and of a date subsequent to the first year of Richard I., which is the time of the commencement of legal memory. If it can be shown, either by evidence of persons living, by record, or writing, or by any other admissible evidence, that the alleged usage began since the first of Richard I., the prescription cannot be maintained. Repeated usage also must be proved in order to support the prescription, but an uninterrupted enjoyment for twenty years has been considered sufficient proof, where there is no evidence to show the commencement of the enjoyment. [PRESUMPTION.]

The thing prescribed for must be something definite. It must also be reasonable; and it must not be inconsistent with any established principle of law; for instance, it is said that a sheriff cannot prescribe for taking gifts for doing the duties of his office. It follows generally, that there can be no prescription to do any wrong or commit nuisance, or for a thing contrary to a statute. No prescription is good which is against the king's right (subject to the limitations hereafter mentioned), conformably to the maxim, Nullum tempus occurrit regi; yet a grant from the crown may be presumed.

Where a man prescribes for a thing which cannot be granted or aliened without deed, he must prescribe in himself, and in his ancestors, whose heir he is; and he cannot prescribe in himself and those whose estate he hath; for he cannot have their estate without deed or other writing which ought to be showed to the court. But of things appendant to an manor or to other lands or tenements, a man may prescribe that he and they whose estate he hath, have been seised of those things as appendant to the manor or to such lands and tenements time out of mind of man. And the reason is, that such manor or lands and tenements may pass by alienation without deed. (Litt., § 183.)

From the nature of the claim of prescription, it follows that a man cannot make a title to land by prescription, for the evidence of a title to land is quite different from and inconsistent with that of a thing claimed by prescription, which only applies to incorporeal things. A man may prescribe for all franchises and privileges which he may have, without a title appearing on record, as for waifs, estrays, wreck, treasure trove; and to have a park or warren, to have a fair, market, or right to toll, &c.

Nothing can be prescribed for at the present day that may not be the subject of grant; for the allegation of usage time out of mind must be usage of something which could originate in a lawful way. When, then, the claim of prescription is allowed, it is equivalent to admitting that there was an original grant which is now lost. (Luttrel's case, 4 *Rep.*, 86.) It is however no proof of a grant.

A question has been raised whether the same thing may be claimed by prescription and by custom, which is nearly the same thing as saying, whether the same thing could be granted to all the inhabitants of a given place, and also granted to one person in that place, either in gross or in respect of a piece of land; as for instance, whether a private right of way may not exist together with a public right of road. (Blewett *v.* Tregonning, 3 A. and E., 586.) If *all* prescription supposes an original grant, it is an inconsistency to suppose a grant to A, and a grant of the same thing to A and others with him.

There is some confusion in the books as to prescription and custom, and the real distinction between them has perhaps not always been observed. It seems immaterial whether the thing whose origin is unknown is called prescription or custom, for the two incidents of time and usage belong to both. Still there is the distinction as to the persons who claim, which has been already stated; and there is of course a difference in the evidence, which results from the difference in the persons claiming, or in whose right it is claimed.

A prescription may be lost or destroyed in various ways. If the thing in respect of which the prescription is claimed is destroyed, the prescription also is destroyed. A franchise by prescription is destroyed if the same liberties are granted by the king by charter. It may be lost by nonusage. But a prescription is not lost by changes which are immaterial and do not affect the nature of the claim: thus if a man prescribes for a watercourse to a fulling-mill, and he converts it into a grist-mill, he does not lose his right, which is generally to have a watercourse to a mill on a given site. And if a corporation should prescribe, and afterwards have a new name, it would not lose the right. (4 *Rep.*, 86.) When the ownership of the land and of the thing claimed out of or upon it are united in the same person, the prescription is destroyed.

Recent acts have made some alterations as to prescription, and limited the time within which actions can be brought or suits instituted relating to real property. The 3 & 4 W. IV., c. 27, applies to every thing of a corporeal nature, which is land in the sense in which land is interpreted in that act; but it only applies to those kinds of property of an incorporeal nature, which are advowsons, annuities, and rents. The 2 & 3 W. IV., c. 100, applies only to cases of modus and exemption from tithes. The 2 & 3 W. IV., c. 71, which is entitled 'An Act for Shortening the Time of Prescription in certain cases,' applies (§ 1) to 'claims which may be lawfully made at the common law by custom, prescription, or grant to any right of common or other profit or benefit to be taken from or upon any land, &c., except such matters and things as are therein specially provided for, and except tithes, rents and services;' (§ 2) 'to any way or other easement, or to any watercourse, or the use of any water,' &c.; and (§ 3) to the use of light. No claim to the things comprised within this statute 'shall, when such right, profit, or benefit (as is mentioned in § 1) shall have been actually taken and enjoyed by any person claiming right thereto, without interruption for the full period of thirty years, be defeated or destroyed by showing only that such right, profit, or benefit was first taken or enjoyed at any time prior to such period of thirty years; but nevertheless such claim may be defeated in any other way by which the same is now liable to be defeated; and where such right, profit, or benefit shall have been so taken and enjoyed as aforesaid, for the full period of sixty years, the right thereto shall be deemed absolute and indefeasible, unless it shall appear that the same was taken and enjoyed by some consent or agreement expressly made or given for that purpose by deed or writing.' As to the rights enumerated in the second section, the terms of twenty and forty years are respectively fixed in the place of the terms of thirty and sixty years mentioned in the first section. Under the third section, which applies to lights, an absolute right to light may be acquired by twenty years' uninterrupted enjoyment, unless the use has been enjoyed by some consent or agreement made or given by deed or in writing. The eighth section provides 'that when any land or water upon, over, or from which any such way or other convenient watercourse or use of water shall have been enjoyed or derived, hath been or shall be held under any term of life, or any term of years exceeding three years from the granting thereof, the time of the enjoyment of any such way or other matter as therein last mentioned, during the continuance of such term, shall be excluded in the computation of the said period of forty years, in case the claim shall within three years next after the end or sooner determination of such term be resisted by any person entitled to any reversion expectant on the determination thereof.' Formerly it was necessary for all persons who claimed in respect of an estate and had not the fee, to claim in the name of the person who had the fee, but under the last-mentioned act 'it shall be sufficient to allege the enjoyment thereof as of right by the occupiers of the tenement in respect whereof the same is claimed, for such of the periods mentioned in the act as may be applicable to the case, and without claiming in the name or right of the owner of the fee, as is now usually done.'

This statute applies also to 'any land or water of the king, his heirs or successors, or any land being parcel of the duchy of Lancaster or of the duchy of Cornwall.'

By the common law a man might prescribe for a right which had at any time been enjoyed by his ancestors or predecessors; but the statute of 32 Hen. VIII., c. 2, enacted that no person should 'make any prescription by the seisin or possession of his ancestor, unless such seisin or possession hath been within threescore years next before such prescription made.' This statute prevented any claim being made by prescription unless there had been seisin or possession within sixty years; but it still allowed the commencement of the enjoyment at any time within legal memory before the sixty years to be proved. The recent act directs that 'the respective periods of years thereinbefore mentioned shall be deemed to be the period next before[*] some suit or action wherein the claim or matter to which such period may relate shall be brought into question' (§ 4); but it only excludes proof of commencement of enjoyment, and it only gives the absolute right, when the several periods of years, reckoned backwards from the time of some suit or action wherein the matter is brought in question, are completed; and it neither excludes the proof nor gives the absolute right if there has been an interruption, within the meaning of this statute, which has been submitted to or acquiesced in 'for one year after the party interrupted shall have had notice thereof, and of the person making or authorising the same.' In these cases, if there has been seisin or possession of the ancestor or predecessor within sixty years, the statute of Henry VIII. will still apply, and evidence of the commencement of enjoyment within legal memory may still be given.

---

[*] Richards *v.* Fry, 7 A. & E., 698.

The acts here enumerated do not apply to a claim 'of a manor, a court leet, a liberty, separate jurisdiction, treasure trove, wreck, waifs, and other forfeitures, fair, market, fishery, toll, park, forest, chace, or any privilege legally known as a franchise, as well as anything pertaining to those rights which come under the description of dignities or offices.' (Mr. Hewlett's *Reply, &c. to certain Evidence before the Select Committee of the House of Commons on Records, February,* 1836.)

The term prescription is derived from the Roman law, but the meaning of the term in the Roman law is different. Blackstone says (iii., c. 17, note F.), 'This title of prescription was well known in the Roman law by the name of usucapio (*Dig.*, 41, tit. 3, s. 3), so called because a man that gains a title by prescription may be said *usu rem capere.*' This remark is not correct. Usucapio in the Roman law was founded solely on possession as such [POSSESSION], and it applied only to 'corporeal things:' 'by the laws of the Twelve Tables usucapion of moveable things was complete in one year; and of land and houses in two years.' (Gaius, ii. 42.) 'To usucapion was afterwards added, as a supplement, the longi temporis præscriptio, that is, an exceptio (plea) against the "rei vindicatio," the conditions of which were nearly the same as in the case of usucapion.' (Savigny, *Das Recht des Besitzes*, p. 6.) The term præscriptio was properly applied to that which a plaintiff (actor) prefixed (præscripsit) to the formula by which he made his demand against a defendant, for the purpose of limiting or qualifying his demand. It seems afterwards to have been used as equivalent to exceptio or plea.

Bracton (ii., c. 22) treats of ownership acquired 'sine titulo et traditione, et per usucaptionem, s. per longam continuam et pacificam possessionem;' but he adds that no time was legally fixed as necessary to make the title perfect, and it depended on the discretion of the justices. It appears then that the rule as to the time of prescription commencing from the first of Richard I. (A.D. 1189) was not established at the time when Bracton wrote, which was in the reign of Henry III. Bracton observes that 'longa possessio,' as above defined by him, 'sicut jus parit jus possidendi et tollit actionem vero domino petenti;' or the actual possession gives in course of time the right to possess. [POSSESSION.] In the same chapter he treats of the mode of acquiring 'possessio rei incorporalis, sicut possessio juris, vz alicujus servitutis per patientiam que trahitur ad consensum, et longum usum et pacificum.' Bracton then makes no distinction between a thing corporeal and incorporeal as to the mode of acquiring right by possession and long usage, nor does he use the word prescription.

(Comyns, *Prescription;* Viner's *Abridgment;* Starkie, *Law of Evidence;* Blackstone, ii., c. 17.)

PRESENTATION. [BENEFICE.]

PRESENTMENT. [JURY.]

PRESS. [PRINTING-PRESS.]

PRESSURE. To explain the use of this term in mechanics we must remember its previous and common use. When we attempt to move matter, or when we sustain a weight, the effect is accompanied by a perception which is called pressure. The sense of touch is nothing but this perception; contact without pressure is not touch, and there are even weights too small to give the sense of touch. A small feather supported on the open palm is not felt, though it would fall to the ground if the palm were removed.

The word pressure is soon indissolubly connected with the notion of motion caused or prevented. Let the obstacle which is pressed suddenly break, and the hand which pressed must follow, unless the person who presses can take an instantaneous warning to cease his effort. Hence, whenever we see motion caused, prevented, or altered, we are apt to carry with us the notion that pressure is exerted. The weight in the scale of a balance is said to press the scale; not that we suppose the scale to have muscles to be acted upon, and nerves to carry news of the action to a living brain, but that we see a counteraction of the known tendency of the weight to fall, and know that if the counteraction were the work of a human agent, that agent would be conscious of the perception of pressure. Hence everything fitted to produce the sensation of pressure, such as a weight, the elasticity of a spring, &c., comes to be called a pressure, and the word loses its meaning of a perception conveyed, and takes that of an agent proper to produce that perception if the human being were situated so as to receive it.

This consideration is not unimportant, for a latent confusion between pressure as a perception, and pressure as a cause proper to produce that perception, has prevented many from a clear understanding of the Newtonian doctrine of gravitation, has caused some to reject it altogether, and has made one or two write books against it. We have in mechanics the word FORCE, which really means nothing but the cause of motion produced, altered, or prevented: but this word force having been used in two distinct senses, namely, both in the sense of pressure and in that of acceleration produced by pressure, it is sometimes necessary to have recourse to the word pressure instead of force where precision of language is required. The motion of the planets is continually altered: there must be a producing cause of that alteration, a force, an agent proper to produce the sensation of pressure in a human being who should interfere with it, if such a thing could be; or, in common language, a pressure. If it is found that the laws of alteration in a planet's motion are such that the pressure must always be directed towards the sun, and if we thence say that the sun attracts the planet, or pulls the planet towards it (pull and pressure being the same terms, or at least only differing in their original meaning by this, that a pull is made towards the agent, and a pressure from him), a person who thus learns the notion of attraction may, without absolutely attributing consciousness to the sun, obtain a rather mysterious notion of attraction from something remaining of the original sense of the word pull or pressure. This it is of course desirable that he should get rid of: but if, from failing to do so, he should be inclined to doubt of what is called attraction, he would do well to remember that by the same rule he should deny that a weight placed in the scale of a balance presses against the scale, or that a weight hung to a beam pulls the beam.

Having said thus much, nothing remains as to the manner of estimating pressures, except to give a reference to the articles FORCE, MASS, MOMENTUM, MOTION (LAWS OF), &c.

We thence collect that in problems of dynamics it is requisite to estimate pressure (in cases in which it cannot be balanced against a weight) by the velocity which it would produce or destroy in a given mass of matter, and in a given time: it being known that the weight of a mass means that pressure which, applied to the mass, would produce in one second 32·19 feet of velocity. An instance of this process occurs in CENTRIPETAL AND CENTRIFUGAL FORCES.

Pressure can only produce an effect in *time;* an instantaneous alteration of velocity (as noted in IMPULSE) being mechanically absurd. But if a pressure produce its whole effect in an imperceptible time, there is all the appearance of an instantaneous destruction or creation of velocity. Suppose a hammer, for instance, to strike an anvil with a velocity of 20 feet in a second. The instant the contact begins both hammer and anvil begin to be compressed, and the compression begins at the rate of 20 feet a second. But the resistance to compression is enormous, and is a pressure which, though it takes time to destroy any velocity, yet will destroy a velocity of 20 feet a second in a very small fraction of a second. The moment the velocity is all destroyed the effort of the anvil and hammer (both of which are compressed) endeavouring to restore themselves, the continuation in fact of the pressure which destroyed the velocity, will give a velocity to the hammer in a contrary direction, or the hammer will rebound, as it is well known to do. In the appendix to Professor Whewell's 'Elementary Treatise on Mechanics' (third or fourth edition), a mathematical investigation of such problems (by Mr. Airy) will be found, upon highly probable hypotheses as to the constitution of matter. The following result of these hypotheses (which cannot be far wrong) will give an idea of the enormous pressures which are created in common cases of what is called impact. If a column of iron three inches high, be let fall on an anvil two feet high, from a height of eight feet, the compression of both hammer and anvil is about one-thousandth of a foot, and the pressure exerted at the moment when it is greatest is that of a quiescent column of iron similar to the hammer in its action, but of no less than 4000 feet high.

PRESTEIGN. [Radnorshire.]

PRESTER JOÃO, 'the Priest John,' was the name given in the middle ages to a supposed Christian sovereign who was said to live somewhere in the interior of Asia. This report appears to have originated with the Nestorians of Mesopotamia, whose missionaries penetrated into Persia, India, and Tartary, and were protected by some of the sovereigns of those regions. [Nestorians.] Oungh, a powerful khan of the Keraïtes, or Krit Tartars, in the eleventh century ruled over a great part of Eastern Tartary, north of the Chinese wall and near the banks of the river Amour. His residence was at a place called Karakorum. Some of the Mongol khans, and among the rest Temugin, afterwards called Gengis Khan, paid allegiance to Oungh Khan. [Gengis Khan.] A war broke out however between Gengis Khan and Oungh, in which the latter was defeated, with the loss of his life, A.D. 1202. Oungh Khan was reported in Europe to be a Christian, and to have taken priest's orders, and some Nestorian missionaries fabricated and published letters said to have been addressed by him to the pope, Louis VII. of France, the emperor of Constantinople, and to the king of Portugal, in which he is made to style himself John the High-Priest. (Petis de la Croix, *Histoire de Gengis Khan.*)

The first European traveller who mentions Prester John was a Franciscan friar, called John Carpini, who was sent, in 1246, nearly half a century after the death of Oungh Khan, by Pope Innocent IV., on a mission to Batou Khan, the son of Gengis, to induce him to restrain the Mongols from their predatory incursions into Russia, Poland, Hungary, and other Christian countries. Carpini did not meet with the Prester John, but appears to have supposed that he lived somewhere farther to the eastward. Several years after Carpini's journey, another Franciscan monk, called Rubruquis, was sent by Louis IX. of France, who was then in Palestine, A.D. 1253-4, as a missionary to Tartary. The story of Prester John was the cause of the mission. Rubruquis, after great difficulties and privations, reached the camp of Batou Khan in Central Tartary, who forwarded him across the deserts to the court of Mangou, the great khan at Karakorum, where Rubruquis found no Prester John, but he found some Nestorian priests, as well as some Mohammedan imaums, with whom he had several interviews, which however he acknowledges were to little purpose, as the parties could not understand each other.

Rubruquis says that the Nestorians had greatly exaggerated their own influence in Tartary, as well as the power of the late Oungh Khan, who appears however to have tolerated and even encouraged Christian missionaries in his dominions.

Mangou gave Rubruquis a letter for the king of France, and ordered him to be supplied with all necessaries for his return home. On his arrival in Palestine, Rubruquis wrote from his convent at Acre an account in Latin of his adventurous journey, which he addressed to Louis, who had returned to France. This curious narrative is written with much simplicity and greater veracity than that of his predecessor Carpini. It is printed in Purchas's collection of travels, and in Bergeron's 'Voyages faits en Asie, par Benjamin de Tudela, Carpin, Rubruquis, &c.'

The existence of a Christian sovereign in Asia called Prester John, continued to be believed in Europe till the end of the fifteenth century, when the Portuguese, having reached India by the way of the Cape of Good Hope, set about looking for Prester John in that country, but without success, though they found a community of Nestorian Christians on the Coromandel coast. At last Pedro Covilham happened to hear that there was a Christian prince in the country of the Abessines [Abyssinia], not far from the Red Sea, and he concluded that this must be the true Prester John. He accordingly went thither and penetrated to the court of the king of Habbesh, who was then in Shoa. [Abyssinian Christians.] It must be remarked however that the 'negus' or king of Habbesh had never assumed the name of Prester John. (Ludolf, *History of Ethiopia*, b. xi.; Tellez, *Historia Geral de Ethiopia*, b. xi.)

PRESTON, a town in Lancashire, in the hundred of Amounderness, on the northern bank of the Ribble, about 15 miles above its mouth, in 53° 46′ N. lat., 2° 42′ W. long.; 190 miles in a direct line north-north-west of the General Post-office, London; 221 miles by the Birmingham, Grand Junction, and North Union railways (a distance traversed by the day mail in 10½ hours); or 213 miles by the coach-road through St. Alban's, Stony Stratford, Daventry, Coventry, Lichfield, Newcastle-under-Lyme, Knutsford, Warrington, and Wigan.

Preston probably arose out of the decay of Ribchester (probably the Coccium of the Antonine Itinerary), now a village about 10 or 12 miles higher up the Ribble. It was held by Tosti or Tostig, son of Earl Godwin and brother of Harold [Harold II.], and was a borough by prescription; the privileges of the burgesses were extended by a charter of Henry II. without date. There was at an early period an hospital here; and Edmund, earl of Lancaster, son of Henry III., founded an hospital for Grey or Franciscan friars; but from what foundation or at what period the town derived its name (Preston, *i.e.* Priest's town) is not known. The town was partly destroyed by Robert Bruce and the Scots, in one of their incursions into England (A.D. 1322). In the great civil war of Charles I. a severe action was fought near the town on Ribbleton Moor (A.D. 1648), when the Duke of Hamilton, who was bringing an army from Scotland to aid the royalist cause, was routed by Cromwell and Lambert. In A.D. 1715, the Jacobite insurgents from Northumberland, under Forster [Northumberland], took possession of the town; but after a brave resistance were obliged to surrender to the royalist forces. In the subsequent insurrection of 1745-46, the Jacobites passed through the town in their retreat: they attempted to entrench themselves here, but withdrew on the approach of the Duke of Cumberland.

The town is on an eminence rising from the north bank of the river, and consists of a number of streets irregularly laid out, but tolerably well lighted and paved. Half a century ago Preston was considered the genteelest town in Lancashire, a distinction which it owed to the number of good families resident in the neighbourhood, to its being the seat of the law courts of the duchy of Lancaster, and to its comparative freedom from the bustle of trade and manufacture. It was then a handsome well-built town, with many good houses. Since then its character has materially changed; it has become the seat of a considerable cotton manufacture; and factories, some of them on a very large scale, and houses are continually in course of erection. Nearly three-fourths of the houses are rated at 5*l.* or less: they are however generally neatly and substantially built of brick; and many are handsome and of large size. Near the town are several handsome villas. The town is supplied with water by an incorporated company. There are several pleasant walks in the neighbourhood, and a waste called 'the moor' adjacent to the town, containing 240 acres, over which the burgesses possessed the right of common, has been lately enclosed and laid out in public walks for the recreation of the inhabitants. There are two bridges over the Ribble: Walton bridge, on the road to Chorley, Wigan, and London, a neat bridge of three arches, built A.D. 1782; and Penwortham bridge, on the road to Liverpool, a bridge of five arches, built in the middle of the last century. The parish church was formerly dedicated to St. Wilfred; but the structure has been rebuilt, and dedicated to St. John. It has a square embattled tower, erected A.D. 1814, with clustered pinnacles. It will hold 1500 persons. St. George's church, built above a century ago, is a brick building, capable of containg 1000 persons. The church of the Holy Trinity capable of containing 1250 persons, was built A.D. 1814. St. Paul's in Park-street, and St. Peter's in the Fylde-road, are both Gothic churches, erected within the last few years by grants from the Parliamentary Commissioners: they are capable of accommodating 1250 and 1450 persons respectively. There are several dissenting places of worship; and at least two Roman Catholic chapels, one of them a very elegant building. There are a custom-house, a town-hall (a neat building of brick), a county sessions-house and house of correction, a modern and convenient building used as a gaol and debtors' prison for the borough; a commodious lock-up house, a neat theatre, a handsome suite of assembly rooms, warm and cold baths, a building for the dispensary, and a house of recovery from fever.

The parish of Preston comprehended in 1831 an area of 14,230 acres and a population of 36,336. It was subdivided into nine chapelries or townships: the borough and township of Preston contained 1960 acres, and a population of 33,112. By the Boundary Act the township of Fishwick (area 600 acres, 759 inhabitants) was added to the borough for parliamentary purposes, and by the Corporation Reform Act for municipal purposes also, making the present area of the borough 2560 acres; the population 33,871. Subsequent increase is supposed to have raised the population to about 40,000. The number of houses in 1831 was 6722, viz. 6299 inhabited, 342 uninhabited, and 81 building; the number of families was 6749, only 130 of which were engaged in agriculture. The staple trade of Preston, till within the last half century, was in linens, for which it was a considerable mart, and some of which were manufactured here. Toward the close of the last century the cotton-manufacture was introduced, and is now the staple of the place, giving employment to 3000 men, besides a greater number of women and boys. There are several iron-founderies, chiefly for making the machinery used in the cotton-manufacture. Some leather is made, and there is a small fishery on the Ribble. The Ribble is navigable at spring-tides for vessels of 150 tons: but it is ill adapted for trade: the shipping which frequent it are all coasters. About 30,000 to 40,000 tons of shipping enter the river or clear out yearly. Coal is brought to the town by the navigation of the river Douglas, which flows into the Ribble just above its mouth. The North Union railroad, and the Manchester and Liverpool railroad, connect Preston with those two great towns, and the Grand Junction and London and Birmingham railroads extend the same means of communication to the midland districts and the metropolis. The Preston and Wyre railroad, now nearly finished, connects Preston with the new harbour of Fleetwood at the mouth of the Wyre. Another railroad, in the course of execution, runs from Preston to Lancaster, another from Preston to Longridge on the Ribble, and a third, branching from the North Union, connects Preston with Chorley, Bolton, and Manchester. The Lancaster canal, which runs from Lancaster to Chorley, where it joins the Leeds and Liverpool canal, passes on the west side of the town, which it connects with the great canal system of the manufacturing districts. There are three weekly markets held in a spacious and well-paved market-place in the centre of the town: the Saturday market is by far the largest of the three, and is principally for corn. There are several yearly fairs; one of these, held early in January, is a great horse-fair.

The borough has been divided, under the Municipal Reform Act, into six wards; it has twelve aldermen and thirty-six councillors. The jurisdiction of the borough magistrates is not exclusive, but the county magistrates do not in fact interfere. Quarter-sessions are held before the mayor, aldermen, and recorder. There is a Court of Record for all personal actions to any amount. Petty-sessions are held nearly every day. A public festival, called a Guild Merchant, is held by the corporation every twenty years; it is commemorated on the first day by a procession of the members of the corporation and of the different trades in characteristic dresses, with bands of music; and by a procession of the ladies of the town and neighbourhood, preceded by girls employed in the cotton-factory, on the next day. Both processions attend the church. The cost of this pageant is usually very considerable. Preston sent members to parliament in the reigns of Edward I. and II., after which the privilege was lost or neglected till the time of Edward VI. The number of voters on the register, in 1835-6, was 4204. Preston is one of the polling-stations for the northern division of the county.

The living of Preston is a vicarage in the archdeaconry of Richmond and diocese of Chester, of the clear yearly value of 665*l.* The perpetual curacies are of the following clear yearly value:—St. George, 161*l.*; St. Paul, 95*l.*; St. Peter, 110*l.*; Trinity, 126*l.* The curate of St. Peter has a glebe-house.

The township of Preston contained, in 1833, an infant-school with 135 children; twenty-seven dame-schools, with 515 children; an endowed grammar-school with 52 boys; another endowed school (the Blue-Coat school), with 25 boys and 25 girls; five subscription charity-schools, with 765 boys and 585 girls; thirty boarding or day schools, with 1318 children of both sexes; and seventeen Sunday-schools, with 2226 boys and 2421 girls. Most of these Sunday-schools have lending-libraries attached. There was no school in Fishwick township. In the other parts of the parish there were two endowed day-schools, with 162 children (118 boys and 44 girls); two other day-schools, with 49 children (23 boys and 26 girls); and five Sunday-schools, with about 280 children. (Aikin's *Environs of Manchester*; *Beauties of England and Wales.*)

PRESTON-PANS, a town and parish in Haddingtonshire in Scotland. The parish extends about two miles along the shore of the Frith of Forth, and about a mile inland. The town of Preston-pans is on the shore of the Frith, about eight miles in a direct line east of Edinburgh. It is divided into two parts by a rivulet flowing into the sea: the western part is called the Cuthill or Kuittle. It is a straggling dingy town, chiefly consisting of a single street parallel with the Frith, and studded here and there with salt or other manufactories, which keep the place almost continually enveloped in smoke. (Chambers's *Gazetteer of Scotland.*) There is a small harbour about half a mile west of the town, called Morrison's haven. The manufacture of salt (from which the town obtained the termination of its name, 'pans') is still carried on: there are a soap-house, a brewery, and one or two potteries. A considerable fishery is carried on, and there are coal-pits near the town. Preston-pans is a burgh of barony. The parish, in 1831, had 426 houses, inhabited by 514 families: the total population was 2322, of which about three-fourths were in the town.

The ruins of Dolphingston Castle, once a place of some note, are in the parish.

Preston-pans was the scene of the first pitched battle between the royal forces and the insurgent Highlanders in the rebellion of 1745. On the 20th of September, Sir John Cope, with the royalist troops, amounting to 2100 men, infantry and dragoons, marched from Haddington towards Edinburgh, and encamped near the town of Preston-pans. Here he was surprised on the morning of the 21st by the insurgents. The troops had scarcely time to form in order of battle, when they were charged by the Highlanders: the line was broken by their impetuous onset; the cavalry were soon put to flight, and the infantry, with the exception of about 170 men, were either killed or captured. Colonel Gardner, who commanded a regiment of dragoons, fell in the engagement, gallantly fighting after his regiment had been put to flight. The artillery, tents, baggage, and military chest were all taken by the insurgents, who lost only about 100 men, killed and wounded. This victory was followed by the almost entire occupation of Scotland by the insurgents and the invasion of England by them. It forms a striking incident in Sir Walter Scott's novel of 'Waverley.'

PRESUMPTION. A presumption is variously defined. The following is a definition:—'A presumption may be defined to be a belief as to the existence of a fact not actually known, arising from its necessary or usual connection with others which are known.' (Starkie, *Law of Evidence*, i. 23.) In another passage (p. 1234) the same definition is given in substance, with the word 'inference' substituted for 'belief.'

A fact may be proved by the immediate knowledge of the witnesses to it, which is called direct evidence. If it cannot be so proved, some other fact may generally be proved by direct evidence, from which the fact in question may often be inferred. If such other fact can be proved, and the existence of the fact in question can be inferred, such inference is a presumption. The inference may be either strictly logical or necessary, or it may be only probable, that is, the fact inferred may be true or it may not be true. If we cannot infer from the fact proved that the fact in question may be true, there can be no presumption at all as to such last fact. In all cases then, in order to establish a presumption, there must necessarily be an inference from a fact or facts; but the inference may be either necessary or probable. If necessary, it cannot, by the supposition, be disproved; if probable, it may either be disproved by evidence, or it may not be possible to disprove it for want of evidence, and yet the inference will still only be probable.

Presumptions which are necessary can hardly ever be considered as not conclusive in any system of law. Presumptions which are only probable may by positive law be made as conclusive as necessary presumptions, that is, it may not be permitted to disprove them when they could be disproved; or where such disproving evidence is wanted, and yet the inference is only probable, positive law may give it the same conclusive force as a necessary presumption.

A presumption, when established, that is, a fact when presumed, is legally the same as a fact proved in such manner as the particular system of law requires such fact to be proved. If then the law annexes any legal consequence to a given fact when proved, it annexes the same to it when the fact is legally presumed. It is only by virtue of legal consequences being annexed to facts that they become objects of jurisprudence. The establishment then of a presumption, in a legal sense, is only the establishment of a fact to which certain legal consequences are annexed.

In our own system, the presumption is sometimes made by a judge or a number of judges, and sometimes by a jury, but the consequences are the same. Some writers say that presumptions are either 'legal and artificial' or 'natural.' They divide 'artificial or legal presumptions' into two kinds, immediate and mediate. 'Immediate are those which are made by the law itself directly and without the aid of a jury. Mediate presumptions are those which cannot be made but by the aid of a jury.' 'Presumptions may therefore be divided into three classes: 1, Legal presumptions made by the law itself, or presumptions of mere law; 2, Legal presumptions to be made by a jury, or presumptions of law and fact; 3, Mere natural presumptions, or presumptions of mere fact.' (Starkie, p. 1241.)

The first class of presumptions, it is said, are either absolute and conclusive, or they may be rebutted by evidence to the contrary. The presumption of law that a bond was executed upon a good consideration cannot be rebutted by evidence, so long as the bond is unimpeached, that is, so long as it is admitted to be a bond. But though the law presumes that a bill of exchange was accepted on good consideration, it admits evidence to show that such was not the fact. Now this presumption of mere law is nothing more than a fact presumed by a judge or judges, to which fact so presumed, that is, so taken to be true, certain legal consequences are annexed or belong. It is however a very inaccurate expression to speak of a presumption of mere law; for, as the same writer says (p. 1242), 'when the law presumes or infers any fact to which a legal consequence is annexed from any defined predicament of facts, the law in effect indirectly annexes to that predicament the legal consequence which belongs to the presumed fact.'

One presumption of mere law may be opposed by another, and the law, that is, the court, must then decide which is the stronger.

Presumptions of *mere law*, as shown, are such as are made by the court. There are instances of presumptions made by act of parliament, that is, the legislature has declared that a certain fact or facts, when proved, shall be conclusive proof of another unproved fact which is not a necessary, and, it may be, is often not a highly probable inference from the proved fact. A statute of 21 James I., c. 27 (now repealed), made proof of the concealment of the death of a bastard child by the mother conclusive evidence of her having murdered it, unless she could prove that it was born dead. Sometimes an act of parliament declares that a certain presumption shall not be allowed or made. (2 and 3 Wm. IV., c. 71, s. 6.) A presumption of mere law is sometimes called an *intendment* of law.

Presumptions of *law* and *fact* are 'also artificial presumptions which are recognised and warranted by the law as the proper inferences to be made by juries under particular circumstances.' (Starkie, p. 1243.) In other words, these are facts which the law, that is, the court, will allow a jury to presume from other facts proved by direct evidence. When the presumed fact is declared by the jury to be a real fact, or is implicitly contained in their verdict, the legal effect is the same as if it were presumed by the judge. Indeed it is said 'that the inference (made by the jury) is never conclusive,' which appears to mean that there are presumptions which are not necessary, and sometimes may not be highly probable, but they are still such as a jury may make (at least under the direction and advice of the court), and their verdict will be good. 'Thus a jury is required, or at least advised by a court to infer a grant of an incorporeal hereditament after an adverse enjoyment for the space of twenty years unanswered.' (Starkie, p. 1244.) On this subject it is said in another passage (p. 1214), 'the presumption of right in such cases is not conclusive; in other words, it is not an inference of *mere law* to be made by the courts, yet it is an inference which the courts advise juries to make whenever the presumption stands unrebutted by contrary evidence. Such evidence in theory is mere presumptive evidence; in practice and effect it is a bar.'

The third class contains 'the natural presumptions of *mere fact*.' 'They are wholly independent of any artificial legal relations and connections, and differ from presumptions of mere law in this essential respect, that those depend upon or rather are a branch of the particular system of jurisprudence to which they belong; but mere natural presumptions are derived wholly by means of the common experience of mankind from the course of nature and the ordinary habits of society.' (Starkie, p. 1245.) This class of presumptions properly belongs to a jury, and yet the courts will sometimes make presumptions of this kind without the aid of a jury. These presumptions then are such as a jury may make without the advice or direction of the court, and 'it seems to be a general rule that whenever there is evidence on which a jury have founded a presumption according to the justice of the case, the courts will not grant a new trial.' (Starkie, p. 1247.)

Though this division of presumptions is far from being characterised by precision, it cannot be denied that it is a kind of index to the practice of the courts as to presumptions. The division is founded—first, on the fact that certain presumptions, which are by no means necessary consequences from the facts proved, are admitted by the judges either as conclusive, or as valid, till they are disproved; these presumptions are sometimes made by the court, but when it is necessary, the court will permit or advise the jury to make them, in order to arrive at a conclusion as to the fact in question: and second, it is founded on the different functions of the judge and the jury, the former declaring the law, and the latter finding the facts, when their assistance for that purpose is necessary.

These presumptions of *mere law*, whether made by the court or by the jury under its direction, are really artificial rules of proof which have been established by judicial decisions, or which in any new case the court upon due consideration will make, and if necessary will direct the jury accordingly.

In those courts where there is no jury, one ground of the classification made by Starkie does not exist, and the judge makes his presumptions either in conformity to the technical rules of his court in cases to which they apply, or he makes his presumptions in cases where there are no technical rules, just as a jury does or any indifferent persons do upon facts submitted to them for their consideration.

Presumption then is either a positive rule by which a certain conclusion is declared by statute, or by the judges, or by the jury under the direction and advice of the judges, to follow from certain other proved facts; or it is a conclusion from certain other proved facts which a judge or a jury may make if they find the probative force of the proved facts sufficient to induce them to make the inference called by Starkie a natural presumption, or presumption of mere fact. Presumptions therefore are incident to every head of law in which proof is required; and the presumptions which are positive rules of law are part of the law of the things to which they relate.

The term 'præsumptio' occurs occasionally in the 'Digest,' and in the sense of an inference from a fact proved or admitted. (*Dig.*, 22, tit. 3, s. 25.)

PRESUMPTIVE HEIR. [Descent.]

PRE'VESA, a town in European Turkey, on the north side of the entrance of the Gulf of Arta, in 38° 57′ N. lat. and 20° 49′ E long. The origin of Prevesa is not known; it is about three miles distant from the ruins of the antient Nicopolis founded by Augustus Cæsar in commemoration of his naval victory of Actium. Its situation, and perhaps its commercial prosperity, made it an object of desire to the Venetians, who obtained possession of it in 1684, and it was subsequently confirmed to them by the treaty of Passarovitz. It appears to have been a dependency of the Seven Islands, and in 1798 came with them into the hands of the French by virtue of the treaty of Campo Formio. War having broken out between France and the Porte, Ali Pacha of Albania sent 5000 men, under his son Mouctar, to attack Prevesa. The French garrison (less than 1000 strong) and the townsmen marched out to encounter the assailants, but were entirely defeated by the Albanians, who took and plundered Prevesa, the population of which is said at this time to have amounted to 10,000 or 12,000. The oppressive government of Ali quickly reduced the population and annihilated the previously flourishing commerce of the town. The streets were deserted, most of the houses, and all the churches except one, were destroyed. Ali made Prevesa his chief naval station, fortified the town with new works, and adorned it by the finest palace or seraglio in his dominions, built at the entrance of the bay. Some new and handsome houses were built by the Turks and Albanians who settled here, but Prevesa has never recovered its prosperity under the Turkish yoke. In 1825 the town suffered much from an earthquake.

Prevesa has probably a population of from 3000 to 4000, and may still be regarded as the principal outlet of the trade of the Gulf of Arta. The chief articles of export are grain, especially wheat and maize, timber, oil, tobacco, cotton, and wool; capotes, or Albanian cloaks, are also important articles of trade. The corn is chiefly sent to the Ionian Islands, to Malta, and to various parts of Italy. The timber is the growth of the forests on the southern shores of the gulf. It is sent chiefly to Malta, for building and firewood. The cotton and cotton-yarn are chiefly from Thessaly. The imports are coffee, sugar, common cloth, velvet, iron goods, fire-arms, &c. (Holland's and Hughes's *Travels in Albania*, &c.)

PRICE. [VALUE; WAGES.]

PRICE, RICHARD, was born at Tynton in Glamorganshire, February 23, 1723. His father Rice Price, of whose second marriage Richard was the sole offspring, was a rigid Calvinistic minister, remarkable for his intolerance, who spared no pains to imbue his son with sound Calvinistic doctrine. Richard however began early to claim the privilege of free opinion, and by his scruples often incurred the anger of his parent. The latter died in 1739, and by his will the bulk of the property, which appears to have been considerable, came into the possession of one son, the widow and six other children being left in straitened circumstances to provide for their own maintenance. The widow and the eldest son survived this event only a few months, and shortly after Richard, then in his eighteenth year, resolved on proceeding to London in the hope of qualifying himself for the clerical profession. The heir of his father's fortune provided him with both horse and servant as far as Cardiff, but left him without the means of performing the rest of the journey except on foot or in a waggon. His education during his father's lifetime had been superintended by several dissenting clergymen, and on reaching the metropolis, through the interest of a paternal uncle, he obtained admission to a dissenting academy, where he pursued his studies in mathematics, philosophy, and theology. In 1743 he engaged himself as chaplain and companion to the family of Mr. Streathfield of Stoke Newington. Here he continued to reside during the ensuing thirteen years, at the end of which the engagement terminated by the death of Mr. Streathfield, who left him some small property. About the same time his circumstances were further improved by the death of his uncle, and by his receiving the appointment of morning preacher at Newington Green Chapel. He married in 1757. The year following he published his 'Review of the principal Questions and Difficulties in Morals,' 8vo., Lond., 1758 and 1787, a work which, though designated by Brown as 'very elaborate, very tedious, but not very clear,' seems to have established his reputation as a metaphysician and moralist. In 1767 he was applied to by a committee of gentlemen connected with the legal profession for his opinion of a plan which they contemplated adopting in order to secure an annuity to their surviving widows. This drew his attention to the defective character of the principles upon which many similar societies had been already instituted, and induced him to write his 'Treatise on Reversionary Payments,' 8vo., Lond., 1769, the publication of which was the almost immediate cause of the dissolution of several of those societies, and the beneficial modification of others. It has since passed through five editions, the last is that edited by Mr. Wm. Morgan, in 2 vols. 8vo., Lond., 1803.

In 1776 appeared his 'Observations on Civil Liberty and the Justice and Policy of the War with America.' So highly was this work appreciated by the advocates of American independence, that an application was made to the author to permit the publication of a cheap edition, which he readily conceded, and thus, observes Mr. Morgan, 'sacrificed all private emolument to the support of a cause from which he could not possibly derive any other benefit than the consciousness of having endeavoured to deserve well of mankind.' In a few months nearly 60,000 copies are said to have been disposed of, and among the many congratulatory addresses which he received on the occasion, the corporation of London testified their 'approbation of his principles and the high sense they entertained of the excellence of his observations on the justice and policy of the war with America' by presenting him with a gold box enclosing the freedom of the city. Two years later (1778) the American Congress, through their commissioners, Dr. Franklin and others, communicated to him their desire to consider him a citizen of the United States, and to receive his assistance in regulating their finances, assuring him that, in the event of his deeming it expedient to remove with his family to America for that purpose, a liberal provision should be made for requiting his services. This invitation was declined, on the ground of his being ill qualified to render the assistance sought, his connections with this country, and his fast advancement into the evening of life; adding, that he looked to the United States as being then the hope and likely soon to become the refuge of mankind.

Dr. Price died in London in 1791, surviving but few years his wife and several of his most eminent and intimate friends, among whom were Dr. Adams, master of Pembroke College, Oxford, Mr. Howard, the philanthropist, and Dr. Franklin. During the latter part of his life he suffered severely from an affection of the bladder. The honorary degree of Doctor of Divinity was conferred upon him in 1769 by the University of Glasgow, solely through the instrumentality of his friends, and apparently without their intentions having been previously made known to him. He was a firm believer in the immateriality of the soul, and considered that the Scriptures authorised the opinion that there is no state of action or perception between death and the eternal judgment. Drs. Priestley and Price, notwithstanding their frequent controversies, were always on terms of the closest friendship. Speaking of the latter, Dr. Priestley remarks—'Perhaps the sentiments of no man's mind were ever more clearly perceived in the natural expression of them than those of Dr. Price. . . Such simplicity of manners, with such genuine marks of perfect integrity and benevolence, diffused around him a charm which the forms of politeness can but poorly imitate.'* His disinterestedness was conspicuous in all his dealings, and, as a rule, he expended one-fifth of his income on charitable objects. For further information the reader is referred to the 'Memoirs of the Life of Richard Price, D.D., by William Morgan, F.R.S.,' London, 1815, 8vo., from which this notice has been principally drawn.

The works of Dr. Price not already referred to are:—1, 'Four Dissertations on Providence, Prayer, the state of Virtuous Men after Death, and Christianity,' 8vo., 1766, 1768; 2, 'The Nature and Dignity of the Human Soul,' 8vo., 1766; 3, 'An Appeal to the Public on the subject of the National Debt,' 8vo., 1772, 1774; 4, 'An Essay on the Present State of the Population in England and Wales, with Morgan on Annuities,' 8vo., 1779; 5, 'The Vanity, Misery, and Infamy of Knowledge without suitable Practice,' 8vo., 177 ; 6, 'An Essay on the Population of England from the Revolution to the present time,' 8vo., 1780; 7, 'The State of the Public Debts and Finances at signing the Preliminary Articles of Peace in January, 1783,' 8vo., 1783; 8, Postscript to same, 8vo., 1784; 9, 'Observations on the Importance of the American Revolution and the Means of making it useful to the World,' 8vo., 1784; 10, 'A Discourse on the Love of our Country,' 8vo., 1789, 1790; 11, 'Britain's Happiness and its full Possession of Civil and Religious Liberty briefly stated and proved,' 8vo., 1791; 12, Sermons, viz. 'Fast Sermons,' 1759, 1779, 1781, &c.; 'Sermons on Various Subjects,' 8vo., 1786, 1816; 'Sermons on the Christian Doctrine,' 8vo., 1787; 13, 'On the Expectations of Lives, the increase of Mankind, the influence of great towns on Population, and particularly of the state of London, with respect to healthfulness and number of inhabitants,' Phil. Trans., 1769; 14, 'On the Insalubrity of Marshy Situations,' Ib., 1774; 15, 'On the Difference between the Duration of Human Life in Town and in Country Parishes and Villages,' Ib., 1775; 16, 'Short and Easy Theorems for finding in all cases the difference between the values of Annuities payable yearly, half-yearly, quarterly, and monthly,' Ib., 1776; 17, 'On the Proper Method of calculating the Value of Reversions depending on Survivorship,' Ib., 1790; 18, 'On the Effect of the Aberration of Light on the Time of the Transit of Venus over the Sun's Disk,' Ib., 1790. The 'Transactions' of the year 1763 contain an essay on the solution of a problem in the theory of probabilities, which, though not entirely the work of Dr. Price, requires to be noticed under the present article. The problem was: 'Given the number of times an unknown event has happened and failed; required the chance that the probability of its happening in a single trial lies somewhere between any two degrees of probability that can be named,' and belongs to that division of the theory termed 'inverse probabilities,' the more important of the two, and which may be said to have originated with this problem, since it was the first of the kind that was answered, and, notwithstanding its practical utility, no successful attempt had been previously made to answer it. Dr. Price found a solution in an unfinished state among the MSS. of the then late Rev. Mr. Bayes, F.R.S., and his chief merit consisted in immediately appreciating its importance, and directing his mind to its improvement and extension. A supplement to the solution was inserted by Dr. Price in the 'Transactions' of the following year, shortly after which he was elected a member of the Society.[*]

---

* 'Sermon preached at Hackney by Dr. Priestley on the occasion of the death of Dr. Price,' p. 20.

PRIDEAUX, JOHN, an English bishop, was born at Stowford, near Ivybridge in Devonshire, September 17th, 1578. His father, being in humble circumstances, and having a large family, could give him only a common education. While yet in his boyhood he was a candidate for the office of parish-clerk at Ugborow, a neighbouring village, but he did not succeed, and to this failure he used to attribute his elevated position in after-life. He was then noticed by a lady of the parish, who maintained him at school till he had acquired a knowledge of Latin, and he then went to Oxford, and was admitted a poor scholar at Exeter College, in 1596: he was elected probationer fellow of his college in 1602, being then B.A. In the following year he received holy orders, and having become noted for his profound knowledge of divinity, as well as his great learning in general, he was elected rector of his college upon the death of Dr. Thomas Holland in 1612. In 1615 he succeeded Dr. Robert Abbot, then promoted to the see of Salisbury, as Regius Professor of Divinity, canon of Christ Church, and rector of Ewelme. He afterwards held the office of vice chancellor for several years. 'In the rectorship of his college,' says Wood, 'he carried himself so winning and pleasing by his gentle government and fatherly instruction, that it flourished more than any house in the university with scholars, as well of great as of mean birth; as also with many foreigners that came purposely to sit at his feet to gain instruction.' He no less distinguished himself in the divinity chair, which he occupied twenty-six years. In 1641, he was consecrated bishop of Worcester, but on account of his adherence to the king he found his dignity neither pleasant nor profitable. He became so impoverished as to be compelled to sell his books, and so was, as Dr. Gauden says, *Verus librorum helluo*. 'Having,' continues Wood, 'first by indefatigable studies digested his excellent library into his mind, he was after forced again to devour all his books with his teeth, turning them by a miraculous faith and patience into bread for himself and his children, to whom he left no legacy but pious poverty, God's blessing, and a father's prayers.' He died of a fever, at Bredon in Worcester, July 12, 1650.

The works of Bishop Prideaux were numerous, and mostly written in Latin, upon grammar, logic, theology, and other subjects. Wood describes him as 'a plentiful fountain of all sorts of learning, an excellent linguist, a person of a prodigious memory, and so profound a divine, that he was called 'Columna fidei orthodoxæ, ingens scholæ et academiæ oraculum,' &c. Though he died before the publication of the London Polyglott, he was well known to the editor Brian Walton, who appeals to his authority on the nicer points of Hebrew criticism, in vindicating the Polyglott from certain cavils that had been raised against it. Bishop Prideaux had a son named Matthias, who was born in 1622, and died of the small-pox in 1646. He was a fellow of Exeter College. After his death, in 1648, was published, in small 4to., a work of his entitled 'An easy and compendious Introduction for reading all sorts of Histories,' with a 'Synopsis of Councils,' added by his father. This book was several times reprinted, but it would now probably be thought more curious than useful, though it might furnish some valuable hints to persons engaged in teaching. (Wood's *Athenæ Oxonienses;* Todd's *Life of Brian Walton;* Chalmers's *Biographical Dictionary*.)

PRIDEAUX, HUMPHREY, was born at Padstow in Cornwall, May 3, 1648, of an antient and honourable family well known in that county. He was sent to school first to Liskeard, then to Bodmin, and was removed thence to Westminster, to be placed under Dr. Busby. Here he was soon chosen king's scholar, and after three years he was elected to Christ Church, Oxford, where he became a student in 1668. He commenced B.A. in 1672, and shortly after, under the direction of Dr. Fell, he published an edition of the historian Lucius Florus. He took his degree of M.A. in 1676, and in the same year he published, by appointment of the University, the inscriptions of the Arundel Marbles with a comment, in one vol. folio, under the title of 'Marmora Oxoniensia ex Arundellianis, Seldenianis, aliisque conflata, cum perpetuo Commentario,' of which a corrected edition was published in 1732 by Michael Maittaire. In 1679 Prideaux was presented by lord-chancellor Finch to the rectory of St. Clement's, Oxford, and in the same year, being appointed Dr. Busby's Hebrew lecturer at Christ Church, he published two tracts of Maimonides with a Latin translation and notes. In 1681 he was installed prebendary of Norwich, and in the following year was made B.D., and shortly afterwards was instituted to the rectory of Bladen with Woodstock, in Oxfordshire. He proceeded D.D. in 1686, and having exchanged his living of Bladen for that of Saham in Norfolk, he went to settle upon his prebend in Norwich. Here he became engaged in some severe contests with the Roman Catholics, the result of which was the publication of his work 'The Validity of the Orders of the Church of England made out.' He also took an active part in resisting the arbitrary proceedings of James II. which affected the interests of the Established Church. In 1688 he was collated to the archdeaconry of Suffolk, and, not without due consideration, he took the oaths of allegiance to William and Mary, and acted up to them faithfully, but he always looked upon the non-jurors as honest men, and treated them with kindness and respect. The next four or five years he spent at the parsonage of Saham, and exerted himself to the utmost in discharging his parochial and archidiaconal duties. While the sees of the non-juring bishops were filling up, without the knowledge or desire of Dr. Prideaux, the bishops of London and St. Asaph earnestly recommended him for the diocese of Norwich, but the recommendation did not succeed, and Dr. Moor was appointed. Upon the death of Dr. Pocock in 1691, the professorship of Hebrew at Oxford was offered to Dr. Prideaux, who declined it. In 1694 he resigned his living at Saham, and in 1696 he was instituted to the vicarage of Trowse near Norwich. He published in 1697 his 'Life of Mahomet,' of which three editions were sold off the first year. In 1702 Dr. Prideaux was made dean of Norwich in the room of Dr. Henry Fairfax. On the translation of Dr. Moor from Norwich to Ely, in 1707, Prideaux was advised and encouraged to apply for the vacant see, but he was not at all disposed to seek for such advancement. This year he published 'Directions to Churchwardens,' a work which has often been reprinted. The best edition is that corrected and improved by Mr. Tyrwhitt, Lond., 1833. In 1710 appeared Dr. Prideaux's work upon 'Tythes,' 1 vol. 8vo., which he had projected in 4 vols., but his plan was defeated by 'the calamitous distemper of the stone,' to use his own language; and this year he resigned the vicarage of Trowse. His disease was the occasion of much suffering and loss of time, and it entirely disabled him from public duties. But he still pursued his private studies, and at length, in 1715, he brought out the first part of his principal work, the 'Connection of the History of the Old and New Testament, and the second part in 1717, folio. This has been one of the most widely circulated books in the English language, and it has still a peculiar value among several more recent works of a similar design. It was the last work that he published. His strength had been long declining, and he died November 1, 1724, in his 77th year, and was buried in Norwich cathedral. About three years before his death he presented his collection of Oriental books, more than 300 in number, to the library of Clare Hall, Cambridge. Several posthumous tracts and letters, with a 'Life of Dr. Prideaux,' the author of which is not named, were published in 1748 8vo. Dr. Prideaux was a man of varied and solid learning and of great moral worth and ardent piety.

---

[*] It was in the above paper that the important theorem was first announced, viz., that the propability in favour of an hypothesis is proportional to the probability which that hypothesis gives to observed events (Lacroix, *Traité des Prob.*, p. 149, third edit.); but as Mr. Lubbock, in his 'Essay on Probability,' published in the 'Library of Useful Knowledge,' observes, either Bayes or Price appears to have confounded the chance of the probability of the event's happening being comprised within the proposed limits, with the probability itself.

(Wood's *Athenæ Oxonienses; Life*, as above; *Letters by eminent Persons.*)

PRIEST (Saxon, *preoster;* French, *prêtre* (prestre); Dutch, *priester;* Spanish, *presbytero,* all remotely from the Greek *πρεσβύτερος, an elder*, and immediately from the Latin *presbyter*), in its popular acceptation, is the name of a minister of religion in all ages and countries.

Priest is used to express the Greek *hiereus* (ἱερεύς) and the Latin *sacerdos*, which signify in general a sacrificer. Whatever may be the primitive meaning of the Hebrew כֹּהֵן (*cohen*), it is rendered in the Septuagint by ἱερεύς, and its usage plainly shows that it denotes a sacrificer. An elder, זָקֵן (*zaken*), has πρεσβύτερος as its corresponding word. In Wiclif's New Testament, which is a translation from the Vulgate, priest, answering to the Latin presbyter, several times occurs, where the Authorised Version has elder; e.g. *Acts*, xiv. 23, 'And whanne thei hadden ordeyned prestis to hem bi alle citees;' c. xv. 2, 'The apostlis and preestis,' which, in v. 4 is 'The apostlis and the eldre men;' *James*, v. 14, 'Prestis of the chirche.'

Priest, in the formularies of the Church of England, is used in its original sense of presbyter, and points out the second degree of the ministers, to be admitted to which a man must be, according to the 34th canon, of the age of 'four and twenty years complete.'

The existence of an official person to act in some way between the Deity and man appears among the earliest notices of history, whether sacred or profane. In the *Book of Genesis*, Melchizedek is named 'Priest of the most high God.' Among the Jews an order of men existed who were especially appointed by God to minister in holy things, and whose qualifications and functions are set forth at large in the writings of Moses. The Egyptians had great numbers of priests, and they had lands in the time of Joseph. (*Gen.*, xlvii. 22.) In the first ages of the Greeks, the same person was mostly their priest and king. In the course of time the office of priest became distinct, and sometimes women, as well as men, were appointed to this office. It is probable however that the most antient priesthood among all nations was that which fathers or heads of families exercised over their own dependents; and thus it will appear that kingly government and sacerdotal authority of some kind or other would naturally spring from the paternal relation. (Shuckford's *Connection of Sacred and Profane History.*)

PRIESTLEY, JOSEPH, the son of Jonas Priestley, a cloth-dresser at Birstal-Fieldhead, near Leeds, was born at Fieldhead, March 13, 1733, old style. His mother dying when he was six years of age, he was adopted by a paternal aunt, Mrs. Keighley, by whom he was sent to a free grammar-school in the neighbourhood, where he was taught the Latin language and the elements of the Greek. His vacations were devoted to the study of Hebrew under a dissenting minister; and when he had acquired some proficiency in this language, he commenced and made considerable progress in the Chaldee, Syriac, and Arabic; but whether with or without the assistance of a tutor does not appear. In the mathematics he received some instruction from Mr. Haggerstone, who had been educated under Maclaurin. From his habits of application and attachment to theological inquiries, his aunt early entertained hopes of his becoming a minister. Ill health however, which in many cases induces a preference of a studious to a more active life, led him to abandon for awhile his classical studies, and apply himself to mercantile pursuits. We learn from his own statement that his constitution, always far from robust, had been injured by a 'consumptive tendency, or rather an ulcer in the lungs, the consequence of improper conduct when at school, being often violently heated with exercise, and as often imprudently chilled by bathing, &c.' Without the aid of a master, he acquired some knowledge of the French, Italian, and German. With the return of health his earlier occupations were resumed, and at the age of nineteen (1752), he entered the dissenting academy at Daventry (now 'Coward College,' London), conducted by Mr. (afterwards Dr.) Ashworth, the successor of Dr. Doddridge. His parents were both of the Calvinistic persuasion, as was also his aunt, who had omitted no opportunity of inculcating the importance of the Calvinistic doctrine. As however differences of opinion on doctrinal points were not with her sufficient ground for rejecting the society of those whom she believed to be virtuous and enlightened, her house became the resort of many clergymen whose views were more or less opposed to those of Calvin. In their discussions young Priestley took considerable interest, and they may be supposed to have had considerable influence in leading him to a systematic examination of the grounds upon which he had rested his own belief. Before the age of nineteen he styles himself rather a believer in the doctrines of Arminius, though he adds, 'I had by no means rejected the doctrine of the Trinity or that of the Atonement.' Before leaving home, he expressed a desire to be admitted a communicant in the Calvinistic congregation which he had been in the habit of attending with his aunt; but the minister having elicited from his replies that he entertained doubts relative to the liability of the whole human race to 'the wrath of God and the pains of hell for ever,' on account of the sin of their first parent, his admission was refused.

On reaching the academy he found the professors and students about equally divided upon most questions which were deemed of much importance, such as liberty and necessity, the sleep of the soul, &c., and all the articles of theological orthodoxy and heresy, which thus became topics of animated and frequent discussion. The spirit of controversy thus excited was in some measure fostered by the plan for regulating their studies, drawn up by Dr. Doddridge, which specified certain works on both sides of every question which the students were required to peruse and form an abridgement of for their future use. Before the lapse of many months, he conceived himself called upon to renounce the greater number of the theological and metaphysical opinions which he had imbibed in early youth, and thus, he himself observes, 'I came to embrace what is generally called the heterodox side of every question: . . . . but notwithstanding the great freedom of our debates, the extreme of heresy among us was Arianism, and all of us, I believe, left the academy with a belief, more or less qualified, of the doctrine of the Atonement.' During his residence at the academy, he composed the first part of his 'Institutes of Natural and Revealed Religion,' published in 1772; the remaining three parts appeared in 1773-74.

On quitting the academy in 1755, he became minister to a small congregation at Needham-Market in Suffolk, at an average salary of 30*l.* per annum. To increase his income, he circulated proposals for teaching the classics, mathematics, &c., for half-a-guinea a quarter, and to board his pupils for 12 guineas a year. Finding these produced no effect, and that his congregation, on becoming acquainted with his opinions, were gradually forsaking him, which however may be in some measure ascribed to an increasing impediment in his speech, he quitted Needham in 1758, for a similar but temporary engagement at Nantwich in Cheshire. Here he was more successful as a schoolmaster, and by means of the strictest economy was able to purchase some philosophical apparatus, including an air-pump and electrical-machine, and also to keep out of debt, which, through life, he always made a point of doing. While at Needham, he informs us that a careful examination of the Old and New Testaments convinced him that 'the doctrine of the Atonement, even in its most qualified sense, had no countenance either from scripture or reason,' and induced him to compose his work entitled 'The Scripture Doctrine of Remission, which shows that the Death of Christ is no proper Sacrifice nor Satisfaction for Sin; but that Pardon is dispensed solely on account of a personal Repentance of the Sinner,' which was published in 1761, the year in which he removed from Nantwich, to succeed Mr. (afterwards Dr.) Aikin, as tutor in the languages and belles-lettres at Warrington academy. Here he married the daughter of Mr. Wilkinson, an ironmaster of Wales, a lady of great amiability and strength of mind, by whom he had several children. Here also he composed several works, among which are his lectures on 'The Theory of Language and Universal Grammar' (1762); on 'Oratory and Criticism' (1777); on 'History and General Policy' (1788); on 'The Laws and Constitution of England' (1772); an 'Essay on a Course of Liberal Education for Civil and Active Life' (1765); 'Chart of Biography' (1765); 'Chart of History' (1769), &c. A visit to the metropolis was the occasion of his introduction to Dr. Franklin, Dr. Price, and others. To the first of these he communicated his idea of writing a historical account of electrical discoveries, if provided with the requisite books. These Dr. Franklin undertook to procure, and before the end of the year in which Priestley submitted to him the plan of the work he sent him a copy of it in print, though five hours of every day had been occupied in public or private teaching, besides which he had kept up an active philosophical correspondence. The title of this work is 'The History and Present State of Electricity, with 'Original Experiments,' 1767 (third edition, 1775).[*] Shortly before (1766) its publication he was elected a member of the Royal Society, and about the same time the honorary title of Doctor of Laws was conferred upon him by the University of Edinburgh. The approbation bestowed on his 'History of Electricity' induced him some time after to compose his 'History and Present State of Discoveries relating to Vision, Light, and Colours,' 2 vols. 4to., which he intended should be succeeded by a similar account of the other branches of experimental science; but the sale of this work not answering his expectations, the design was abandoned, and, we believe, the work itself did not evince any very intimate knowledge of the subject.

A disagreement between the trustees and professors of the academy led to his relinquishing his appointment at Warrington in 1767. His next engagement was at Mill-Hill chapel, Leeds, where his theological inquiries were resumed, and several works of the kind composed, chiefly of a controversial character. The vicinity of his dwelling to a public brewery was the occasion of his attention becoming directed to pneumatic chemistry, the consideration of which he commenced in 1768, and subsequently prosecuted with great success. His first publication on this subject was a pamphlet on 'Impregnating Water with Fixed Air' (1772); the same year he communicated to the Royal Society his 'Observations on Different Kinds of Air,' to which the Copley medal was awarded in 1773.

'No one,' observes Dr. Thomson, 'ever entered upon the study of chemistry with more disadvantages than Dr. Priestley, and yet few have occupied a more dignified station in it, or contributed a greater number of new and important facts. The career which he selected was new, and he entered upon it free from those prejudices which warped the judgment and limited the views of those who had been regularly bred to the science. He possessed a sagacity capable of overcoming every obstacle, and a turn for observation which enabled him to profit by every phenomenon which presented itself to his view. His habits of regularity were such that everything was registered as soon as observed. He was perfectly sincere and unaffected, and the discovery of truth seems to have been, in every case, his real and undisguised object.' He discovered oxygen gas, nitrous gas, nitrous oxide gas, nitrous vapour, carbonic oxide gas, sulphurous oxide gas, fluoric acid gas, muriatic gas, and amoniacal gas. The first of these, which he named dephlogisticated air, he discovered in 1774, having obtained it by concentrating the sun's rays upon red precipitate of mercury. [OXYGEN.] He showed that the red colour of arterial blood resulted from its combination with the oxygen of the atmosphere; that the change produced in atmospheric air during the processes of combustion and putrefaction arose from a similar abstraction of oxygen; and recognised the property possessed by vegetables of restoring the constituent thus abstracted. Moreover the pneumatic apparatus now used by chemists was principally invented by him. 'But though,' observes Dr. Thomson, 'his chemical experiments were for the most part accurate, they did not exhibit that precise chemical knowledge which distinguished the experiments of some of his contemporaries. He never attempted to determine the constituents of his gases, nor their specific gravity, nor any other numerical result.' Of this he himself was doubtless aware; for in a letter written many years after (1795), he observes, 'As to chemical lectureship, I am now convinced I could not have acquitted myself in it to proper advantage.....Though I have made many discoveries in some branches of chemistry, I never gave much attention to the common routine of it, and know but little of the common processes.'

The theory promulgated by Lavoisier, though founded on the discoveries of Cavendish and Priestley, was never adopted by the latter, who continued to adhere to the phlogistic theory notwithstanding the many facts and arguments adduced against it.

While at Leeds, very advantageous proposals were made to him to accompany Captain Cook in his second voyage to the South Seas; but when about to prepare for his departure, it was intimated to him by Mr. (afterwards Sir Joseph) Banks, that objections to his religious principles had been successfully urged by some of the ecclesiastical members of the Board of Longitude.

In 1773, through the recommendation of Dr. Price, he received the appointment of librarian and literary companion to the Earl of Shelburne, with a salary of 250*l.* a year, a separate residence, and a certainty for life in the event of his lordship's death or their previous separation. In the second year of this engagement he accompanied his patron through France, Flanders, Holland, and Germany. At Paris his philosophical publications procured for him an easy introduction to several of the leading chemists and mathematicians, whom he describes as professed atheists; and by whom he was told that he was the only individual they had ever met with, and of whose understanding they had any opinion, who was a believer in Christianity. To combat their and similar prejudices, he wrote his 'Letters to a Philosophical Unbeliever, containing an examination of the principal objections to the doctrines of natural religion, and especially those contained in the writings of Mr. Hume' (1780); to which he afterwards added the 'State of the Evidence of Revealed Religion, with animadversions on the two last chapters of the first volume of Mr. Gibbon's History of the Decline and Fall of the Roman Empire' (1787). While resident with Lord Shelburne, who allowed him 40*l.* a year towards defraying the expenses of his chemical experiments, he printed the first four volumes of his 'Experiments and Observations on Air,' 1774-1779; a fifth appeared in 1780. He also wrote his 'Miscellaneous Observations on Education' (1778), and an 'Introductory Dissertation' to Hartley's 'Observations on Man.' In this dissertation, having expressed his doubts concerning the immateriality of the sentient principle in man, he was denounced in most of the newspapers and other periodicals as an unbeliever in revelation and an atheist. This led to the publication of his 'Disquisitions relating to Matter and Spirit' (1777), wherein his object is to show that man is wholly material, and that our only prospect of immortality is from the Christian doctrine of a Resurrection.' In the same year appeared his work on the 'Doctrine of Necessity.'

The cause of the separation between Priestley and Lord Shelburne (1780) has never transpired, and does not appear to have been known to Priestley himself. Some have attributed it to the odium to which the works last mentioned subjected their author, and to the invidious attacks which issued in almost all quarters from the press; but whatever may have been their true motives, the conduct of both appears to have been strictly honourable. Priestley retired with an annuity of 150*l.* a year, and in 1787 Lord Shelburne made overtures for renewing the original engagement, which however Priestley thought proper to decline.

Among the many points of church doctrine which, as we have seen, were successively repudiated by Dr. Priestley, it is remarkable that the doctrine of the Trinity should not have been hitherto included, at least not in the same unqualified manner. In a letter to Mr. Henderson, dated August, 1774, he has left a confession of his faith at that time. 'I believe,' he writes, 'the prophecies in our Bible were given by God; that the gospels are true; that the doctrine of original sin is absurd; that the spirit of God only assists our apprehension; that the foreknowledge of God, held by the Arminians, is equal to the decree of God held by the Calvinists; that they are both wrong; and the truth is, the pains of hell are purgatory. Many things I yet doubt of; among these are the Trinity and the mediation of Christ.'

On leaving Lord Shelburne, he became minister to the principal dissenting congregation at Birmingham, and a subscription was entered into by his friends for defraying his philosophical experiments and promoting his theological inquiries. His receipts from these sources must, by his own account, have been very considerable. Offers were also made to procure him a pension from government, but this he declined. In 1782, he published his 'History of the Corruptions of Christianity,' 2 vols. 8vo. A refutation of the arguments contained in this work was proposed for one of the Hague prize essays; and in 1785 the work itself was burnt by the common hangman in the city of Dort. It was succeeded by his 'History of Early Opinions concerning Jesus Christ,' 1786, 4 vols. 8vo.

A literary warfare now ensued between Priestley and Dr.

---

[*] His 'Original Experiments,' though numerous and interesting, did not give rise to any discovery of importance, and the entire work is described by Dr. Thomson as 'carelessly written,' which may readily be attributed to the rapidity with which it was executed.

Horsley, by both of whom it was carried on with much warmth. In a letter to Dr. Price, dated Birmingham, January 27, 1791, he says, 'With respect to the church with which you have meddled but little, I have long since drawn the sword and thrown away the scabbard, and am very easy about the consequences.' But he did not confine himself to dealing with churchmen: his object was to obtain for the dissenters what he considered to be their rights, and in the pursuit of which he published about twenty volumes. He attacked certain positions relating to the dissenters in Blackstone's *Commentaries* with a vigour and acrimony which seem to have surprised his more courteous and feeble adversary.

His 'Familiar Letters to the Inhabitants of Birmingham,' from the ironical style in which they were written, exasperated even the populace, urged on by party malice and bigotry. His Reply to Burke's Reflections on the French Revolution, an event to which the lower orders of Birmingham were at that time unfavourably disposed, led to his being nominated a citizen of the French republic; and the occasion of a public dinner given by some of his friends, July 14, 1791, in celebration of the anniversary of the destruction of the Bastile, at which however Priestley himself was not present, afforded to an ignorant mob the opportunity of gratifying the malignity which they conceived they had grounds to entertain towards him. After demolishing the place where the dinner had been given, they broke into his house, destroyed his philosophical apparatus, a valuable collection of books, and a large number of manuscripts, the result of many years' labour, after which they made an unsuccessful attempt to burn the dwelling and what was left in it. [Birmingham.] An eye-witness of the 'riots' asserts that the high road, for full half a mile of the house, was strewed with books, and that on entering the library there was not a dozen volumes on the shelves, while the floor was covered several inches deep with the torn manuscripts. In the meantime, he and his family were forced to seek safety in flight. The first two nights he passed in a post-chaise, the two succeeding on horseback, but owing less to his own apprehensions of danger than to those of others. The sum awarded to him at the assizes as compensation for the damage is not stated, but he tells us that it fell short of his loss by 2000*l.* Individual generosity made amends. Among other instances of this kind, his brother-in-law made over to him the sum of 10,000*l.* invested in the French funds, besides an annuity of 200*l.* a year.

After this he removed to Hackney as the successor of his deceased friend Dr. Price; but finding his society shunned by many of his former philosophical associates, among whom were the members of the Royal Society, from whom he formally withdrew himself, and seeing no prospect of enjoying permanent tranquillity in England, he determined on quitting it. Accordingly, April 7, 1794, he embarked with his family for America, and took up his abode at Northumberland in Pennsylvania. A few days before his embarkation he was presented with a silver inkstand bearing the inscription, 'To Joseph Priestley, LL.D., &c., on his departure into exile, from a few members of the University of Cambridge, who regret that this expression of their esteem is occasioned by the ingratitude in their country.' He had contemplated no difficulty in forming a Unitarian congregation in America; but in this he was greatly disappointed. He found that the majority disregarded religion; and those who paid any attention to it were more afraid of his doctrines than desirous of hearing them. By the American government, the former democratic spirit of which had subsided, he was looked upon as a spy in the interest of France. 'The change,' he writes in a letter dated Sept. 6, 1798, 'that has taken place is indeed hardly credible, as I have done nothing to provoke resentment; but being a citizen of France, and a friend to that Revolution, is sufficient. I asked one of the more moderate of the party whether he thought if Dr. Price, the great friend of their own Revolution, was alive, he would now be allowed to come into this country. He said, he believed he would not.'

His wife died in 1796. His youngest son had died a few months previous. He himself, in 1801, became subject to constant indigestion and difficulty of swallowing any kind of solid food. This continued to increase till 1803, when, perceiving his end approaching, he told his physician that if he could prolong his life for six months, he should be satisfied, as in that time he hoped to complete the works upon which he was then engaged. These were his 'General History of the Christian Church from the Fall of the Western Empire to the Present Time,' 4 vols., 1802-3 (which had been preceded by his 'General History of the Christian Church to the Fall of the Western Empire,' 2 vols., 1790), and 'The Doctrines of Heathen Philosophy compared with those of Revelation' (posthumous). He died February 6, 1804, expressing the satisfaction he derived from the consciousness of having led a useful life and the confidence he felt in a future state in a happy immortality. On his death becoming known at Paris, his éloge was read by Cuvier before the National Institute. There is a statement in more than one work that Priestley's death was occasioned by poison, but it does not appear to be supported by any authority.

The auto-biography of Dr. Priestley, originally written, as he informs us, during one of his summer excursions, concludes with the date 'Northumberland, March 24, 1795.' It was published in America after his decease, with a continuation by his son Joseph Priestley, and observations on his writings by Thomas Cooper (president judge of the fourth district of Pennsylvania) and the Rev. William Christie. Priestley's Correspondence has been collected and incorporated with the above memoir by Mr. John Towill Rutt, forming the first two volumes of his collected edition of Priestley's 'Theological and Miscellaneous Works,' in 25 vols. 8vo., Hackney, 1817, &c. At pp. 537-544 of the second volume of this edition will be found, chronologically arranged, a complete list of Priestley's works; an imperfect list is given in Watt's 'Bibliotheca Britannica.'

(Thomson's *Annals of Philosophy*, 8vo., vol. i., 1813; Thomson's *History of the Royal Society*, 4to., 1812; Cuvier's 'Notice of the Life of Priestley,' in the *Biographie Universelle;* the articles 'Electricity' and 'Chemistry' in the *Encyclopædia Metropolitana*, by the Rev. Francis Lunn; Rutt's *Memoir and Correspondence of Priestley*, above mentioned, &c.)

PRIMATE. [Archbishop.]

PRIMA'TES, the name given by Linnæus to the first order of *Mammalia*, and thus characterised by him:—Dentes primores incisores; superiores iv., paralleli. Mammæ pectorales ii.

The order contains the following genera:—

Homo, of which Linnæus records two species, viz. *Homo sapiens* and its varieties (Man), and *Homo Troglodytes* (Homo sylvestris, Orang Outang, *Bout.*).

Simia, thirty-three species.

Lemur (including *Lemur volans*). [Pleuroptera.]

Vespertilio, six species. [Cheiroptera.]

End of Volume the Eighteenth.

Printed by William Clowes and Sons, Stamford-street.
